In the field of solid state physics, A. J. Forty (University of Warwick) reported experiments on absorption and reflectivity measurements which are contributing significantly to knowledge of band structures. Photoemission from surfaces is also providing new possibilities in metallurgy. D. A. Urtch (Queen Mary College, London) said that chemists on the other hand were exploring the possible use of synchrotron radiation to study the atomic components of molecular orbitals by way of X-ray emission spectroscopy. The new ring would allow an extension of current work to the light elements where X-ray emission is less favoured. The polarised nature of the radiation offers a valuable new tool in studies of single crystal structures throughout the ultraviolet and X-ray regions. Of more immediate interest to molecular biologists, however, are the intensities of some $10–10^5$ over conventional continuum X-ray sources that could become available. J. C. Hazelgrove (Medical Research Council, Cambridge) discussed advantages of these radiations in studies of transient states where it is important to have detailed short exposure X-ray diffraction pictures of specimens whose decay under normal sources alters vital characteristics during the time of exposure.

On the instrumental side, P. J. Key (National Physical Laboratory) said that the synchrotron, as a standard of relative spectral distribution throughout the near ultraviolet to the X-ray region, is becoming well established and radiometry problems are being studied. A discussion on X-ray optics introduced by M. Hart (University of Bristol) showed that fluxes some 10^5 greater than obtainable with conventional sources can be expected when the polarised nature of the synchrotron radiation is exploited. Quarter wave plates, crystal spectrometers and the development of X-ray diffraction gratings were also discussed.

In spite of the progress made and the enthusiasm of the users, it was evident that NINA and the other synchrotrons, where the users are parasitic to the experiments of the high energy nuclear physicists, are not ideal sources. The parasitic mode of operation is extremely inefficient where users are unable to control the quality and duration of the synchrotron beam. The SRC plan would seem to meet the foreseeable needs of the Reading conference and it was with this in mind that they attended the SRC meeting. Quite properly questions were asked relating to costs, location and long term usefulness of the proposed storage ring. The scientists present were particularly concerned that delays at this stage could result in the United Kingdom being without a source of synchrotron radiation if present plans concerning NINA are adhered to. A preliminary estimate of between 12 and 18 months for the level of funding in the SRC document was given at the meeting. It was agreed that there is every need to impress upon the SRC a sense of urgency in proceeding with the plan beyond the design stage, in order to ensure that the period between the close down of NINA as a synchrotron source and the start up of the new storage ring is kept to an absolute minimum.

Midwinter sunrise at Newgrange

J. Patrick

College of Technology, Bolton Street, Dublin 1, Eire

At Newgrange on the morning of the winter solstice the Sun's rays shine through a specially contrived slit in the roof, along a 19 m passage to illuminate the central burial chamber. This passage grave was built about 1,000 yr earlier than the third phase of Stonehenge, by a different culture. It supports the claim that prehistoric cultures had studied the cycles of the Sun and utilised them in orientating their monuments.

NEWGRANGE is a passage grave in a Neolithic cemetery in County Meath, Ireland, about 30 miles NNW of Dublin (0 301 703). Two large samples of charcoal which were collected from caulking in between the roof slabs, yielded dates of 2475±45 b.c. and 2465±40 b.c. respectively. Depending upon which correction curve is used, this gives an age of 3100±100 BC for the building of the tomb. It consists of a huge, artificially constructed cairn of water-rolled stones, which is approximately 80 m in diameter. A passage, 19 m long, runs into the mound to give access to a large chamber about 3 m square and 6 m high. There are three recesses that open into the chamber, so that the ground plan has a cruciform appearance (Fig. 1). In each of these recesses is a large stone basin which was used to hold the burnt remains of the interred occupants.

Carvings

The tomb has been open to visitors since 1699 and an unknown amount of the original burial deposit may have been removed since then. In 1967 excavation of the tomb floor in front of the basin stones revealed the burnt bone fragments of about five people. These were accompanied by some grave goods characteristic of this type of tomb in Ireland, including stone pendants and beads, stone 'marbles' and bone points.

At the base of the mound is a continuous kerb of large slabs. It is believed that dry-stone walling was built on top of the kerb to a height of 3 m and that this wall was made of quartz for about 30 m on each side of the entrance. The sun on the

(From ref. 1.)

Fig. 2 The decorated Entrance Stone in front of the burial chamber. The roof box can be seen, surmounted by the lozenge relief carving. (Green Studio.)

glistening white quartz would have presented a spectacular sight from the surrounding countryside. Most of this wall collapsed soon after completion of the monument, and the kerb stones became completely buried and remained hidden until uncovered again at the start of this century. Outside the kerb, there are 12 large standing stones that may form part of a circle, but their true relationship with the mound is not known for certain. They may be older than the passage-grave.

One of the most outstanding features of Newgrange is the decoration on the stones. The Entrance Stone, set in front of the passage, is regarded as one of the most impressive pieces of Megalithic art in Europe (Fig. 2). The artist who executed this piece of work has succeeded in using the shape of the stone to the utmost advantage in creating its aesthetic appeal. Another small but remarkable design is the three-spiral figure in the rear recess (Fig. 3). There are many other decorations within the passage and chamber, and on the kerbstones, virtually making Newgrange a Megalithic art gallery.

Astronomical alignment

Perhaps the most interesting feature of Newgrange is the 'roof box'. Dry stone walling has been constructed on top of the passage orthostats to support the second roofslab at a higher level than the first, leaving a gap about 20–25 cm high and 1 m wide (Figs 1 and 2). The gap is protected from the weather by a box like structure of slabs supported on dry walls. This is open to the front. For further protection against the weather, the rear edge of the first roof slab and the front edge of the second roof slab have water channels cut on them. The leading edge of the uppermost roof slab of the roof box has an excellent relief carving of lozenges (Fig. 2).

During the winter solstice in 1969 Professor M. O'Kelly observed that 4 min after sunrise the Sun's rays shone through the roof box, along the passage, and up to the rear recess of the burial chamber, which became fully illuminated (Fig. 4). The spectacle lasted for 17 min before the sun moved out of alignment. Later, Mrs O'Kelly recalled a tradition that at a certain time of the year the sun lit up the three-spiral figure in the end of the chamber[1].

In 1972 Professor O'Kelly asked me to make an accurate survey of the roof box to see if this phenomenon would have occurred when the burial chamber was first built. The passage

Fig. 3 The three-spiral figure in the rear recess of the chamber. (Green Studio.)

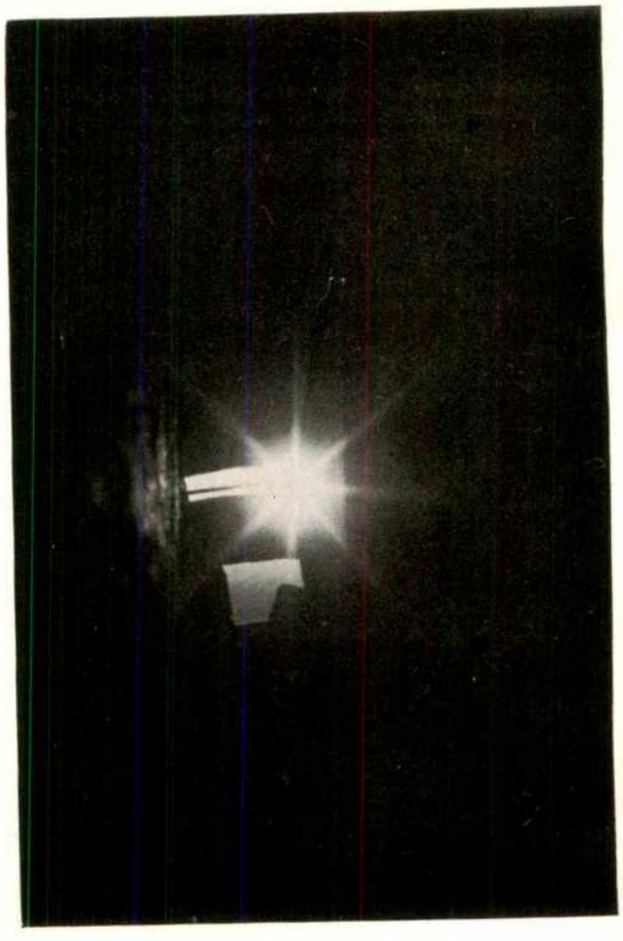

Fig. 4 Sunlight shining through the roof slit during mid-winter solstice. (M. J. O'Kelly.)

is in the form of two curves (Fig. 1), so that for a ray of light to travel directly from the roof box to the back wall of the rear recess it must be in the azimuth range 133° 42′–138° 24′. The elevation of the distant horizon (0° 51′) is the minimum elevation of which the Sun's direct rays can enter the slit. The floor of the chamber is about 15 cm lower than the roof box, so at the minimum elevation sunlight will extend across the floor and into the rear recess. Light rays will not enter the chamber when the elevation exceeds about 1° 40′. This range of azimuths and elevations, reliable to about 15′ and 5′ respectively means that the Sun's rays will shine directly into the chamber if its declination lies between −22° 58′ and −25° 53′. It therefore seems that

the Sun has shone down the passage to the chamber ever since the date of its construction and will probably continue to do so for ever, regardless of secular changes in the obliquity of the ecliptic. It also means that the spectacle occurs for a number of days before and after the winter solstice.

Unfortunately, the vagaries of time have had their effect on the passage and some of the stones are now leaning inwards, thus trimming down the width of the beam of light. At the time of construction the beam would have been about 40 cm wide whereas now it is only 17 cm. The two principal orthostats causing the obstruction are L18 and L20 (Fig. 1). The first 10 orthostats on either side of the passage have been straightened but there is no way of straightening the rest without dismantling the whole structure.

There are about 200 passage graves in Ireland with many more allied tombs in Scotland and Brittany, but to my knowledge none of them has a roof box like that at Newgrange. As this structure is unique, and as the whole monument is so grandiose, it seems likely that its orientation is deliberate.

The monument best known for its astronomical orientations is Stonehenge on the Salisbury Plain. After it had been built, it was remodelled several times, and the main astronomically orientated structures were erected in its third phase, which is dated at around 1800–2000 BC. This is about 1,000 years after the construction of Newgrange, and there is little connection between the two monuments or between the cultures which built them. The unambiguous definition of both direction and altitude at Newgrange is by far the most convincing evidence that some Megalithic structures were deliberately orientated on astronomical phenomena. This must lend greater credence to the theory that different cultures in the British Isles were investigating the basic solar cycles. It is quite possible that data passed between different cultures, so that Stonehenge eventually became an important repository of astronomical knowledge.

I would like to thank Professor and Mrs O'Kelly for their assistance and advice.

Received February 4; revised March 28, 1974.

Structure and orientation of an RNA polymerase operon in *Escherichia coli*

L. Errington, R. E. Glass, R. S. Hayward & J. G. Scaife

MRC Molecular Genetics Unit, Department of Molecular Biology, University of Edinburgh, Mayfield Road, Edinburgh EH9 3JR

The genes for at least two Escherichia coli *RNA polymerase subunits are contained in a single operon.*

THE DNA-dependent RNA polymerase is a key enzyme in expression of the hereditary material. In *E. coli* it consists of at least four different subunits α, β, β', and σ. The structural gene for the β subunit (*rif*) has been precisely located on the genetic map because mutations conferring resistance to the antibiotic rifampicin also result in the sythesis of RNA polymerase molecules altered in this polypeptide[1]. Here we present evidence based on deletion studies, indicating that the structural gene for at least one other subunit, β', is linked to the *rif* gene, and that both share a common promoter (P). These elements map clockwise on the bacterial chromosome in the order *P–rif–*β'. Thus our results provide a clear genetic basis for the suggestion made by Matzura, Molin and Maaløe that β' and β' may be synthesised on a single polycistronic mRNA[2]. In addition, they show that the structural genes and the promoter for this mRNA map clockwise on the bacterial chromosome, in the order *P–rif–*β'.

Because and deletion affecting RNA polymerase would be lethal in haploid cells[3], we have constructed strains partially diploid for the *rif* region of the chromosome by introducing into the cell an F′ factor which carries extensive amounts of chromosomal DNA on both sides of this locus (Fig. 1). Thus deletions into *rif* do not affect cell viability. Moreover we have chosen to isolate such deletions on the F′ factor, because they can easily be characterised by transferring the episome into a variety of appropriately marked strains. To obtain information about the structure and orientation of the operon, we have isolated a specific episomal deletion ending within the *rif* gene, and which extends leftwards into the nearby *arg*CBH operon (Fig. 1). This deletion, which has removed all the DNA immediately to th left of *rif*, has nevertheless left the β' gene carried by the F′ completely intact. This result is expected if the β' gene were adjacent to *rif* and located to its right. Moreover, this deletion also places the synthesis of the β' subunit under the control of the *arg*CBH operon. Since *arg*CBH is read in a clockwise fashion[4], we conclude that the β' and β' genes are both read in that direction.

Isolation of deletions into *rif*

We have developed a simple method for selecting deletion mutations on an F′ factor which simultaneously affect the *rif* gene and its neighbour, *bfe* (ref. 5); mutations in these loci confer resistance to antibiotic rifampicin and the virulent bactriophage BF23 respectivly. Mutations to resistance in either gene are normally recessive to the wild-type allele (ref. 3 and L.E. and J.G.S. unpublished). Thus, a partial heterodiploid of the *bfe*^{s} *rif*^{r}/F′ *bfe*^{s} *rif*^{s} is sensitive to both BF23 and rifampicin. Mutants with deletions inactivating the wild-type *bfe* and *rif* genes carried by the F′ will, however, become resistant to both BF23 and the antibiotic since the only intact *bfe* and *rif* genes remaining in the cell are those conferring resistance. We can therefore readily select for such rare mutants by plating cultures of the partial heterodiploid on solid medium containing rifampicin,

The genotypes of our bacterial strains are shown in Table 1. The strain LE104 was specially constructed for our deletion selection. It was made from AB2147 *ilv arg*H *met*B *thi his lac*Y *gal xyl mal*A *tna str*^{r} (Wechsler, personal communication). In a series of steps the following markers were introduced into AB2147 (Silverstone and Errington, unpublished): *pur*D (cross against a *pur*D derivative of Hfr AB311 (ref. 18); Δ*arg*(C–B)$_{sup102}$ (cross against Hfr P4X sup102 (ref. 6); *rif*-r (spontaneous mutation); *rec*A56 (cross against Hfr KL16 recA56 (ref. 19); *bfe-r* (spontaneous mutation); KLF10$^+$ (cross against AW2).

* The pattern of *ara* and *lac* suppression in this strain is slightly different from that seen in LE210. However its suppressor is still temperature sensitive, since the strain does not grow on nutrient plates at 42° C.

spread with phage BF23 (Table 2).

The starting strain, LE104 (Table 1), carries the KLF10 episome which spans the *arg*CBH-*met*B-*rif*-*pur*D region of the chromosome (Fig. 1). The strain is Rec⁻ to prevent recombination between the episome and the chromosome and, to ensure that the cells retain the KLF10, the chromosome contains mutations in both *met*B and *pur*D. We can also determine whether the *bfe-rif* deletions extend into the nearby *arg*CBH operon, because the chromosome of this strain carries an Arg⁻ mutation (*sup*102)[6]; deletions terminating before *arg*CBH leave the cells Arg$^+$, whereas deletions extending into the *arg* operon will make the cells Arg⁻.

We have found that mutants having the desired Bfe^r Rif^r phenotype arise spontaneously at a frequency of about 3×10^{-8}. The following observations show that these mutants are due to deletions on the F′ factor (Table 2). First, many of them (63%) are Arg⁻ and have therefore lost, in addition to *bfe* and *rif*, one or more of the *arg* genes from the episome. Moreover, these Arg⁻ mutants do not revert to Arg$^+$ ($<10^{-8}$). Secondly, crosses in which the mutant F′ factors are transferred to recipients carrying mutations in *arg*E, C and B generate a deletion map (Table 2) congruent with the known map of the *arg* operon. Three of the deletions, Δ7, 12 and 18, enable us to order two amber *rif*^{0} mutations, *rif*$^0_{amD12}$ and *rif*$^0_{amIII/8}$, which affect the β subunit of RNA polymerase (ref. 7 and R.S.H., S. J. Austin, and J. G. S., unpublished).

Isolation of deletions affecting *rif* and *bfe*. Cultures (5 ml) of LE104 (Table 1), grown overnight in minimal salts[20] containing glucose (0.2%) thiamin (10 μg ml^{-1}) and arginine (20 μg ml^{-1}), were mixed with the virulent phage BF23 (multiplicity of infection = 10) and shaken at 37° C (3 h). They were then concentrated to 0.3 ml by centrifugation and spread in soft agar (2.5 ml) containing 10^{11} p.f.u. of BF23 on three minimal agar plates containing arginine (20 μg ml^{-1}), thiamin (10 μg ml^{-1}) and glucose. After 4 h at 37° C each plate was overlaid with soft agar (3 ml) containing rifampicin (1.2 mg ml^{-1}), giving a final concentration in the plate of 100 μg ml^{-1}. The plates were incubated at 37° C for 2 d.

Characterisation of deletions. Each mutant carrying a deletion on KLF10 was mated against appropriately marked recipient strains by cross-streaking on selective medium[7]. Some combinations were not tried (nt).

Crosses against Arg⁻ recipients. The genotypes of the recipient strains, HTA1, P4XC53, MN8A and HTA19 are listed in Table 1. Deletion strains able to give Arg$^+$ recombinants (+) give confluent growth in the cross streak. Those unable to give recombinants (−) show no growth at all. Note that both *arg*C53 and *arg*B2 are in Hfr strains which only permit the recovery of chromosomal recombinants[21].

Crosses against *rif*^{0} mutants. Each donor was crossed against rif^0 recipients (LE210, 213, Table 1) containing a temperature-sensitive amber suppressor SuIII (A2(P))[17]. Met$^+$ derivatives containing each mutant KLF10 were recovered at the permissive temperature (30° C) on selective medium. They were then tested for the ability to generate *rif*$^+$ recombinants able to grow at the restrictive temperature (42° C). In this table we show the percentage of ts$^+$ cells in a colony of each derivative. Control colonies of the recipient *rif*°$_{amIII/8}$ (LE213) and *rif*°$_{amD12}$ (LE210) gave no more than 0.001% and 0.01% ts$^+$ revertants respectively.

Crosses against a *met*B *pur*D recipient. Our initial selection required that our deleted KLF10 factors retain *met*B and *pur*D (see text). That they do retain these markers was confirmed in crosses against AS 13 *met*B *pur*D.

* Number found in a total of 30 mutants recovered from a single culture of LE104.

† Deduced from the Arg$^+$ phenotype of the parental deletion strains in this class.

Operon containing the *rif* and ß′ genes

One of the mutants selected from LE104 (Table 1), can give Arg⁺ recombinants on transfer of the F factors to *arg*C53, but not *arg*B2, recipients (Table 2). Consequently its deletion, △18, must have one end in the *arg*C-B region of the episome. The other is between rif^{0}_{amD12} and $rif^{0}_{amIII/8}$ (Table 2). If the β′ gene lies just to the right of *rif*, △18 should inactivate *rif* but still leave the β′ gene intact. Cells containing KLF10△18 would thus be expected to have two copies of the gene for β′ and only one for β (located on the chromosome).

We assay the β and β′ subunits of RNA polymerase by electrophoresis of pulse-labelled, whole cell lysates on polyacrylamide gels containing sodium dodecyl sulphate, which separates the large β and β′ subunits from other cell proteins (Fig. 2)[2]. We have studied a number of KLF10△18 diploids in this way. Their behaviour (see below) shows that KLF10△18 still determines β′ subunit synthesis, and implies that the β′ gene lies just to the right of *rif*.

Evidence has previously been obtained suggesting that the β supunit is synthesised before the β′ subunit[2]. Thus, if *rif* lies just to the left of the β′ gene, both could be in a single operon read left to right (clockwise) on the chromosome (Fig. 1). This conclusion leads us to predict that a nonpolar deletion which begins in the *arg*CBH operon and ends in the *rif* gene should place the synthesis of β′ under the control of *arg*CBH, which is read clockwise[4]. Expression of the *arg* genes is subject to negative control requiring at least arginine (or a derivative) and the product of the *arg*R repressor gene[8]. When bacteria are grown in the presence of arginine their *arg*CBH operon is fully repressed, but in its absence, the operon becomes induced and the genes in the pathway are expressed at a (ten-fold) higher rate. Still higher rates of *arg* expression (100-fold) result when cells are prevented from synthesising functional *arg* repressor by mutations in *arg*R. In many *arg*R mutants expression of the operon proceeds at the full constitutive level, unaffected by the presence of arginine in the growth medium[9].

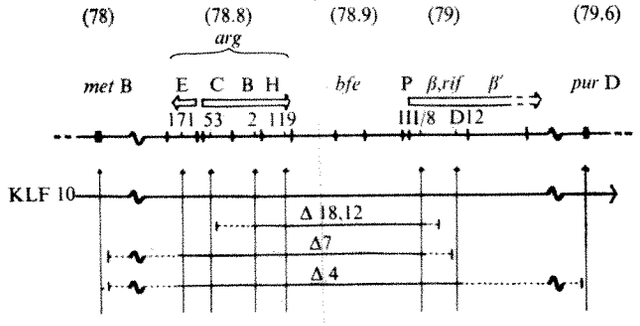

Fig. 1 The *metB-purD* segment of the *E. coli* chromosome. The figure shows the markers used in our genetic analysis, the wild-type KLF10 (omitting sex factor DNA) and the *bfe-rif* deletions isolated on this F′ factor. The arrows at the top of the figure indicate the direction of gene transcription and the numbers in brackets refer to the position of genes (in minutes) on the *E. coli* map[26].

In strains carrying KLF10△18 we are able to detect changes in the overall rate of β′ synthesis due to *arg* of the β′ gene carried by the episome. We find that an arginine-repressed KLF10△18 diploid (Table 3, line 4) synthesises nor more β′ than a normal haploid strain[27] and markedly less than a control KLF10 diploid (Table 3, line 2). In addition, the KLF10△18 diploid synthesises significantly more β′ when grown in the absence of arginine, although the rate of synthesis of β subunit is unaltered (Table 3, line 2). An isogenic control strain carrying wild-type KLF10 synthesises β and β′ at a rate not affected by the presence of arginine (Table 3, lines 1 and 2). More dramatically, we find (Fig. 2 and Table 3, lines 4 and 6) that the specific increase in β′ synthesis in KLF10△18 strains is enlarged about seven-fold as a result of an *arg*R mutation. This *arg*R mutation has an equivalent effect on the synthesis of ornithine transcarbamylase, one of the *arg* enzymes (T. Bretscher and S. Baumberg, personal communication)

Measurement of the amount of β′ synthesised by the KLF10△18 *arg*R diploid enables us to estimate the efficiency of the *arg*CBH promoter, if we assume

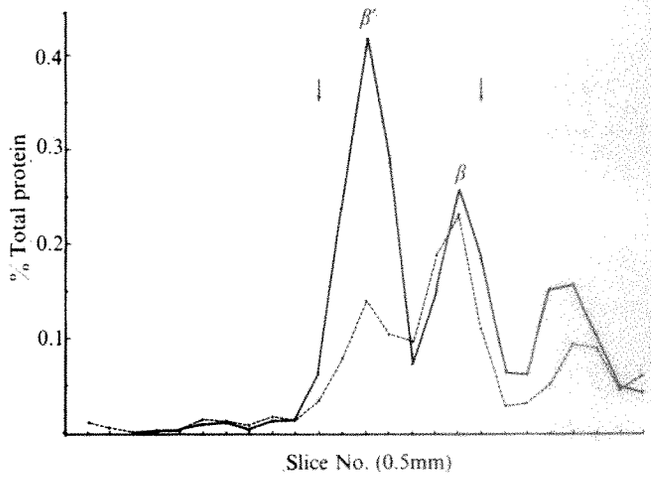

Fig. 2 Gel analysis of ³H-labelled protein in crude lysates of *arg*R⁺ (LE114) and *arg*R⁻ (LE117) strains carrying KLF10 △ 18. Both lysates were prepared from parallel cultures grown in excess arginine (100 μg ml⁻¹) and run with marker polymerase on separate SDS-polyacrylamide gels (Table 1). Only the top of each gel is shown. Fractions from the *arg*R⁺ *and arg*R⁻ lysates are shown by broken and solid lines respectively. The limits of the stained β′ and β subunits of the marker polymerase are indicated by the arrows. % Total protein = (³H per slice)/(³H in total protein applied per gel) × 100.

that △18 is not polar. We ascribe 0.95 (±0.37)% of the total leucine incorporation (pulse label) to arginine-controlled β′ synthesis (Table 3, lines 4 and 6). The mol% of leucine in the β′ subunit (molecular weight, 160,000) is about the same as that for total *E. coli* protein[10]. Thus, assuming that a single cell contains 3.3×10^{-13} g of protein[10], we calculate that the *arg*CBH promoter is set to give about 7×10^{3}–15×10^{3} protein molecules per cell. A comparable level of expression has ben reported for the typtophan operon[11].

Control of the RNA polymerase operon

We have characterised a deletion fusing the *arg*CBH operon to the middle of the *rif* gene, which puts synthesis of the β′ subunit under arginine control. Our finding shows that a gene determining synthesis of the β′ subunit lies to the right of *rif*. This gene, which is read clockwise, is presumably the structural gene for the β′ polypeptide. The episome-coded β′ synthesis we can detect in KLF10△18 diploids is entirely under arginine control. The deletion △18 has therefore removed the normal promoter for β′ synthesis without affecting the DNA sequence between *rif* and the β′ gene. Consequently the promoter for β′ synthesis

Table 3 Synthesis of the β and β′ subunits of RNA polymerase in KLF10 diploids

	Strain No.	*arg*R allele	KLF10	Arginine in culture (μg ml^{-1})	^{3}H in β′ subunit (% total labelled protein)*	P†	^{3}H in β subunit (% in total labelled protein)*	P†

5	LE116	−	wild-type	100	0.57 (± 0.05)		0.84 (± 0.06)	
6	LE117	−	Δ18	100	1.32 (± 0.28)		0.56 (± 0.06)	

*Data in lines 1–4 represent the means of four lysates; those in lines 5 and 6 are means of two lysates. The standard errors of these means are shown in bracket.s

†*P* values indicate the significance of the difference between cultures grown in the presence and absence of arginine computed by the method of paired comparisons[22]; ns indicates the difference was not significant.

The strains used in these experiments are isogenic (Table 1). They were grown in M9 medium[23] without methionine to guard against episome loss.

Preparation of labelled cell lysates. Young M9-minimal cultures (5×10^7 ml^{-1}) were pulse labelled for 1.5 min with 4, 5 ^{3}H-leucine, chased with cold leucine for 2 min and lysed as previously described[13]. We used minimal medium containing 100 μg ml^{-1} arginine to grow cultures repressed for the arginine biosynthetic enzymes.

SDS polyacrylamide gel electrophoresis. We used the buffer system of King and Lemmli[24]. The separating gel (60 mm) had 16% acrylamide, 0.094% NN′-methylene bisacrylamide (Bis), 0.025% ammonium persulphate and 0.025% (v/v), N, N, N′, N′-tetramethylethylene diamine (TEMED); the stacking-gel (10 mm) had 2.5% acrylamide, 0.6% Bis and 0.1% (v/v) TEMED. It was either chemically polymerised with 0.0167%) ammonium persulphate or photopolymerised with 0.0005% riboflavin. Each lysate sample (25 or 50 μl), reheated at 75° C for 5 min, was applied to the gel with bromophenol blue (final concentration 0.0002%) and marker RNA polymerase previously incubated in sample buffer[24]. Samples were stacked at a constant current of 0.375 m per gel at room temperature for approximately 3 h and electrophoresis was continued for a further 21 h at 1.1 m per gel. Gels were stained with 0.1% Coomassie Brilliant Blue R250 in methanol:acetic acid:H_2O (5:1:5) at 37 °for 2 h and destained in 7% acetic acid/5% methanol at 37° C O/N. The β, β′ region was sliced (0.5 mm) and placed in firmly capped scintillation vials containing 2 ml of Petri's permeabilising scintillation fluid[25] and POPOP (0.1 mg^2 ml^{-1}). The vials were incubated in the dark (18 h) at 37° C. The precooled samples were counted for ^{3}H in a Packard liquid scintillation counter. All labelled material was eluted and the efficiency of counting was constant and reproducible. Counts were computed as a percentage of the total protein determined by counting aliquots of whole lysate under identical conditions. This method of total protein estimation gave the same results as the method of Hayward *et al.*[13].

must lie to the left of *rif* and is presumably common to both genes.

Matzura *et al.*[10] find that, under widely different conditions of growth, *E. coli* synthesises the β and β′ subunits as a rather constant fraction of the total cell protein. In addition, no increase in their rate of synthesis is detected following *rif* and β′ gene replication[10] or in strains containing a λ *drif*[1] transducing phage[12]. Nevertheless the cell has the potential to increase in parallel the rates of β and β′ synthesis to a level considerably higher than normal[13]. These combined observations indicate that the cell coordinately regulates synthesis of at least these two subunits. On the basis of the results presented here we suggest that the expression of the *rif* and β′ genes is coordinately regulated at a site on the chromosome to the left of *rif*.

There are a number of candidates for a regulatory molecule acting at this site. For example, polymerase operon expression could be maintained at a constant level throughout the cell cycle if one or more of the polymerase subunits themselves acts as a repressor. An inbuilt self-regulatory function of this type has recently been attributed to operons in several organisms[14–16].

We are able to test whether the β′ subunit alone has the regulatory function suggested. In heterodiploid strains containing KLF10△18 β subunit synthesis is exclusively determined by the chromosomal *rif* gene, subject to normal polymerase operon regulation. A significant part of β′ subunit synthesis, on the other hand, is regulated by arginine rising to a considerable excess (about 2.5-fold) in the *arg*R strain. Thus, if the polymerase operon were self-regulated by the β′ subunit, *arg*R$^-$/KLF10△18 heterodiploids should show a concomitant reduction in the rate of β synthesis. We have been unable to find such a reduction (Table 3, lines 4 and 6) suggesting that repression of the polymerase operon is not achieved by the β′ subunit acting alone at the proposed regulatory site.

We thank Drs J. B. Kirschbaum and W. B. Brammar for their help in the preparation of this paper. We thank Lepetit Pharmaceuticals Ltd., Maidenhead for a gift of rifampicin. L. E. is a Medical Research Council scholar.

Regulation of the expression of the histidine operon in *Salmonella typhimurium*

Takashi Kasai*

Department of Biology, Johns Hopkins University, Baltimore, Maryland 21218

A positive factor enhancing the expression of this operon binds at the promoter, but exerts its effect downstream on a DNA region which acts as an attenuator of transcription.

The histidine operon of *Salmonella typhimurium* consists of nine structural genes, transcribed into a polycistronic mRNA[1-3] (Fig. 1). There are five unlinked regulatory genes: *hisR, S, T, U* and *W*[1]. Products of these genes are thought to be required for the biosynthesis of a His-tRNA species involved in repression as a corepressor[1,2,4,5]. No gene coding for an aporepressor has been found.

Although most investigators have regarded the histidine operon as a model for negative control[1,2], some data suggestive of positive control have appeared recently[6]. All regulatory mutations tested, including *hisR, S,* and *T,* and promoter-operator mutants appear to carry transcriptional regulatory defects, suggesting that the major control mechanism of the *his* operon is at the level of transcription (unpublished data of myself and P. E. Hartman). Here I report evidence of a positive regulatory mechanism required for transcription of the *his* operon and indicate the possible general importance of such positive control mechanisms.

Transcription of wild-type operon

High frequency transducing phage (φ80 λ ^{imm}d*his*$^+$) carrying the *S. typhimurium* histidine operon was isolated by Voll[7]. The regulatory behaviour of a lysogenic strain indicates that the phage retains the intact regulatory segment (G. R. Smith, B. Tong and B. N. Ames, unpublished results) as well as all the structural genes of histidine biosynthesis (Fig. 2*a*).

Phage DNA containing the wild type histidine operon was transcribed by purified *E. coli* RNA polymerase holoenzyme and the product was fractionated through successive hybridisation steps. After the first-step hybridisation to nontransducing phage DNA (Fig. 2*a*), 60–80% of the remaining ^{3}H-mRNA had originated from the bacterial region of the transducing phage. The bacterial RNA was further hybridised to the separated strains of φ80 λ ^{imm}d*his*$^+$ DNA in the presence of excess cold RNA of various kinds (Fig. 2*b*). The cold competitor RNAs were from the following *Salmonella* strains: *his-515,* which is deleted for the entire bacterial region integrated into the phage genome (Fig. 2*b*); *his-712,* deleted for most of the histidine operon and a short distance beyond[3]; and *his01242,* a deletion of the distal portion of the operator region (Fig. 1) causing high constitutive levels of enzyme[8]. Pulse labelled *in vivo* RNA also was isolated from *his01242* cells and hybridised directly to the separated strains of φ80 λ ^{imm}d*his*$^+$ DNA as in the second step of the *in vitro* RNA fractionation (Table 1*b*). Results are expressed as the percentage of RNA transcribed from the bacterial segment of DNA. As Figure 2*b* shows the percentage of RNA derived from the histidine operon is given as the difference between the third and fourth rows for each DNA strand in Table 1*a* and *b*.

The coding strand of the *his* operon is shown to be the *r* strand of the transducing phage DNA (45% of counts in Table 1*b*). Genes outside the histidine operon, possibly including the gene for gluconate-6-phosphate dehydrogenase

a, In vitro RNA was prepared as described by Nakanishi *et al.*[35] with some modifications. All incubations were done at 37° C. The transciption mixture contained Tris(hydroxymethyl) amino methane-HCl, *p*H 7.9, 20 mM, KCl 100 mM, dithiothreitol 0.1 mM, ATP, GTO, UTO, 0.15 mM each, ^{3}H-CTP 0.075 mM (specific activity 12.5 Ci mmol, New England Nuclear Corp.), EDTA (*p*H 8.0) 4 mM, $MgCl_2$ 15 mM, rifampicin (Sigma) 10 μg ml^{-1}, φ80λ^{imm}d*his*$^+$ DNA 25 μg ml^{-1} and RNA polymerase 10 μg ml^{-1}. DNA was first incubated for 2.5 min in the reaction mixture containing Tris-HCl, *p*H 7.9, KCl, dithiothreitol, nucleotide triphosphates and EDTA. RNA polymerase was then added and preincubation was followed for another 10 min. The transcription was started with the addition of excess $MgCl_2$ and was allowed to continue for 10 min. Rifampicin was added together with $MgCl_2$ to select for RNA chains initiated by the preinitiation complex. The total volume of the final reaction mixture was 125 μl. After the reaction was terminated by the addition of 0.5 ml of the stopping solution[35] containing DNase I, the reaction mixture was incubated at 0° C for 20 min. 0.5 ml of 0.1 M Tris-HCl, *p*H 7.2, containing 1% sodium dodecyl sulphate (SDS) and one drop of 20 mM acetic acid were added. RNA was isolated with *p*H 5.2 phenol and run through the double layered column of Dowex AG50W-X8 (K$^+$ form) and Sephadex G-25. (ref. 36). RNA polymerase was prepared from *E. coli* N7060 cells lacking RNase I and polynucleotide phosphorylase by the method of Burgess *et al.*[37]. The preparation had no detectable protein contamination on polyacrylamide gel electrophoresis with SDS. Cold *S. typhimurium* RNAs used in competition were isolated from exponentially growing cells. Hybridisations were carried out in two steps as described in Fig. 2. *b*, Each 155,000 c.p.m. (12.5 μg) of *in vivo his01242* ^{3}H RNA was hybridised to the separate strands as described in Fig. 2*b*. Preparation of *in vivo* ^{3}H RNA is described in Table 2.

* Present address: Universita di Napoli, Facolta di Medicina e Chirurgia, Instituto di Patologia Generale, via Sergio Pansini, Naples.

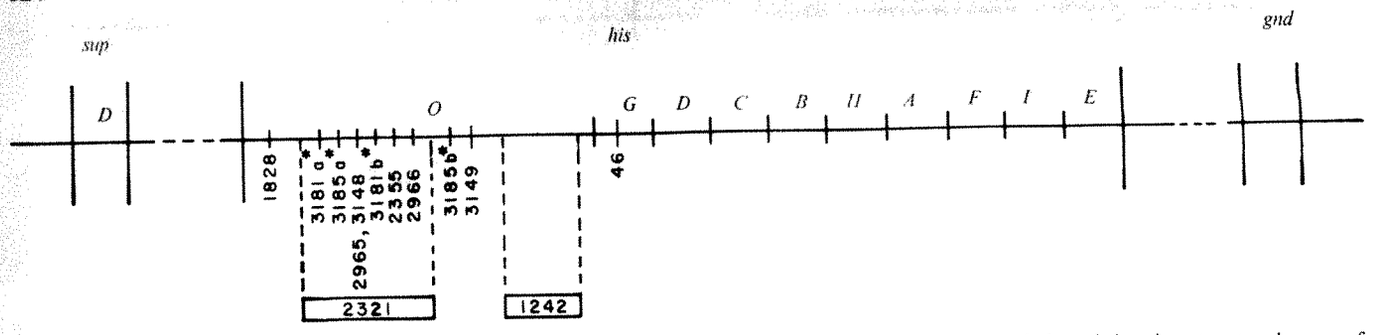

Fig. 1 The histidine operon of *Salmonella typhimurium*. The *his* operator-promoter region has been expanded, and the nine structural genes of the operon, *hisG* through *hisE*, are depicted[3]. Two outside markers, *supD* and *gnd*, are shown. Mutation 46 is a mis-sense mutation in the *hisG* gene; all other numbers refer to operator-promoter mutations. Genetic mapping of the operator-promoter region (*O*), approximately 300 nucleotide pairs long, was carried out by B. Ely, D. B. Fankhauser and P. E. Hartman (unpublished results).
* It is proposed that these mutants have more than one altered site.

(*gnd* in Fig. 2), may be preferentially transcribed from the *l* strand (52% of counts from *l* strand in Table 1*b*). *E. coli* tRNA gave competition no greater than *his-515* RNA, indicating that the entire transcribable region of the bacterial DNA carried by transducing phage is deleted in mutant *his-515*. Compared with the high level of *in vivo* *his01242* expression, the percentage of histidine mRNA henceforth called *his* mRNA) is very low when transcribed *in vitro* on φ80 λ ^{imm}d*his*$^{+}$ DNA as template (*r* strand in Table 1*a* compared with *r* strand in Table 1*b*). Since the level of *his* mRNA is compared with that of the neighbouring genes the results indicate that purified RNA polymerase, for some reason, does not support transcription of the wild type histidine operon to the same extent as transcription of the adjacent DNA regions.

Transcriptional barrier on DNA

Mutation *his01242* has been incorporated into the histidine transducing phage (G. R. Smith, B. Tong and B. N. Ames, unpublished results). When φ80 λ ^{imm}d*his01242* DNA is used as template for purified RNA polymerase, *in vitro* expression of the histidine operon is high relative to that from the external bacterial region and is essentially the same level as that found for *in vivo* expression of *his01242* (Fig. 3*a*). This high rate of transcription *in vitro* is not unique for a particular RNA polymerase or DNA preparation. These results agree with the observation that *his01242* DNA supports much more synthesis of L-histidinol dehydrogenase (encoded by the *hisD* gene) than does wild type DNA in coupled and uncoupled systems of *in vitro* protein synthesis (J. Broach, S. Artz and B. N. Ames, unpublished results). Such results indicate the presence of a DNA region which lowers the expression of the histidine operon *in vitro*. Removal of this region in the deletion mutant *his01242* allows purified RNA polymerase to transcribe the histidine operon at a greatly enhanced frequency.

DNA was isolated from phage carrying the promoter-type mutation, *his02355*. Although *his02355* expression is reduced about 50-fold *in vivo* (B. Ely and Z. Ciesla, unpublished results), φ80 λ ^{imm}d*his02355* DNA gives a level of *in vitro* transcription similar to wild type DNA (Fig. 3*a*). As expected in such experiments, the *l* strand shows low levels of hybridisation to ^{3}H-RNA within the histidine operon (Fig. 3*b*). The low levels found may be the result of read-through from preceding initiation sites or abnormal initiations.

The high level of transcription of *his01242* DNA by purified RNA polymerase indicates that it is neither binding of the RNA polymerase nor RNA chain initiation which is regulated in the DNA region deleted in *his02142*. The DNA region, therefore, must either block the elongation of RNA chains in transcription or expel RNA polymerase from the template in its travel towards the initiation site. If it is the elongation of the RNA chain that is regulated, the positive factor might act as an antiterminator.

Positive factor binds at promoter site

The genetic structure of the regulatory segment of the *his* operon has been determined (B. Ely, D. B. Fankhauser and P. E. Hartman, unpublished results) in conjunction with studies on enzyme levels (B. Ely, personal communication) and mRNA levels (unpublished data of myself and P. E. Hartman). I now focus on the most critical of these observations.

Most of the promoter-like mutations cluster upstream with respect to the *his01242* deletion (Fig. 1). The *in vivo* *his* mRNA levels of some typical promoter mutants with different genetic backgrounds are shown in Table 2. There are two kinds of promoter mutations: class I responds to the mutation *hisT1504* which produces a tRNA^{His} that is still active in protein synthesis but is not active as an effector of the *his* operon[4,5,9,10]. Class II has lost the response to *hisT1504* or retains a very low level of response. Even though they cannot respond well to *hisT1504*, three mutations (class II*B*) respond to essentially the full level of expression when they are combined as double mutants with *his01242* (last column of Table 2). It is extremely difficult to explain this phenomenon by a model exclusively involving

Table 2 Histidine mRNA levels* of promoter type mutants in different genetic backgrounds.

Strain	Type of promoter mutation	Second mutation		
		None	*hisT1504*	*his01242*
0+	Wild type	8	50	100
03181	I	8	33	44
03185	I	5	34	—
03148	IIB	10	4	98
02965	IIB	3	3	94
02355	IIA	4	5	5
02321	IIA	10	8	5
02966	IIB	8	4	92
03149	I	13	22	—

Strains were grown in the E medium of Vogel and Bonner[38] containing 0.1 mM L-histidine (repressed condition). Exponentially growing cells were pulse labelled for 3 min with ^{3}H-5-uridine (New England Nuclear Corp.), and lysed with dodecylamine and SDS (ref. 39). ^{3}H-RNA was isolated with phenol[36] and hybridised to denatured φ80λ^{imm}d*his*$^{+}$DNA and φ80λ^{imm}DNA retained on Millipore filters. The relative amount of mRNA was determined from the initial slope of the *his* operon-specific DNA-RNA hybridisation curve plotted against an increasing amount of *in vivo* ^{3}H-RNA. The methods will be described elsewhere in detail.
—, Not tested.
*The level of *his01242* was taken as 100.

negative control. The RNA polymerase binding site *per se* is not impaired in class II*B* mutants. And, if *his01242* is the site to which the repressor binds, why is it that inactivation of the corepressor in the *hisT* strain does not cause depression as does a deletion in the operator region?

The paradox is resolved by the following considerations. (1) The class II*B* promoter mutations reduce the binding of a positive factor. (2) The positive factor increases the expressibility of the *his* operon in the presence of the DNA region deleted in *his01242*. (3) Class II*B* mutants respond poorly to the *hisT1504* mutation simply because the positive factor is necessary to receive, either directly or indirectly, the altered information from the *hisT1504* mutation. Similarly, class II*B*/*hisG46* (Fig. 1) double mutants grown on histidinol fail to exhibit normal physiological derepression (B. Ely, personal communication).

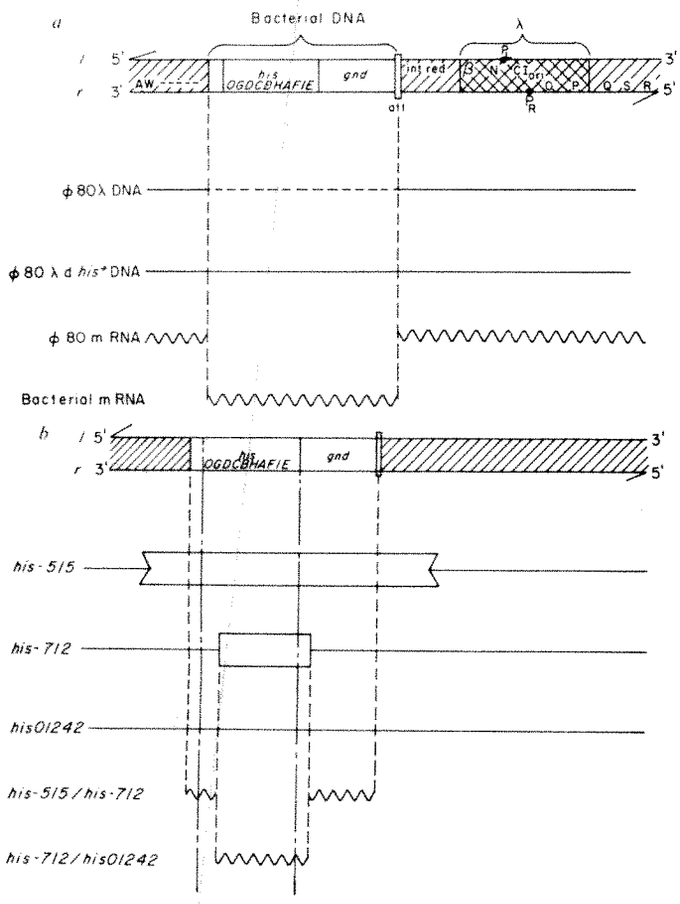

Fig. 2 Separation of histidine mRNA by two-step hybridisation. The strain used to grow the transducing phage was an *E. coli* *his* deletion mutant, doubly lysogenic for φ80λ^{imm}d*his*$^+$ and φ80λ^{imm} phages. φ80λ^{imm} carries the heat-sensitive mutation, CI857. The transduced segment of bacterial DNA carries the *gnd* gene in addition to the *his* operon[7]. This segment is tentatively located to the left of *att* since there is not enough phage chromosome between *att* and *ori* to accommodate the transduced segment. The *ori* function is required for the propagation of this phage[30] and the lower density of the φ80λ^{imm}d*his*$^+$ virion with respect to φ80λ^{imm} (my unpublished data) indicates that the transducing phage has lost more phage DNA than is replaced by the bacterial DNA segment. Phage from heat induced lysogens were purified by polyethylene glycol precipitation[31] and DNA was isolated from both types of phage after separation through CsCl (ref. 32). Strand separation of the transducing phage DNA was done by CsCl centrifugation in the presence of poly(U,G)[33]. Unseparated DNA strands were immobilised for DNA-RNA hydridisation on Millipore nitrocellulose filters (HAWP 047 00, Millipore) according to the method of Gillespie and Spiegelman[34]. Each filter of 6 mm diameter contained 6.7 μg DNA. *a*, in the first step hybridisation, 90,000 c.p.m. of *in vitro* ^{3}H-RNA was incubated with four filters which retain unseparated φ80λ^{imm} DNA strands in 150 μl of 4 × SSC (0.15 M NaCl, 15 mM sodium citrate) containing 2 mM CTP and 0.2 mg *E. coli* tRNA per ml (General Biochemicals Co.). Cold CTP was added to chase from the filter ^{3}H-CTP remaining in the *in vitro* ^{3}H-RNA preparation. Hybridisations were carried out for 15 h at 75° C in small glass vials with screw caps. To determine the proportion of bacterial RNA in this preparation, a 25 μl sample of the first hybridisation mixture was separately transferred to a vial containing two filters of φ80λ^{imm}d*his*$^+$ DNA and φ80λ^{imm}DNA, filled up to 50 μl with 4 × SSC and incubated for 8 h at 75° C. The filters were counted as described below and the purity (*P*) of the bacterial RNA was determined as follows:
P (%) = [(c.p.m. hybrid on φ80λ^{imm}d*his*$^+$DNA − c.p.m. hybrid on φ80λ^{imm}DNA)/c.p.m. hybrid on φ80λ^{imm}d*his*$^+$DNA] × 100
b, After quenching in an ice bath, a 25 μl sample of the first hybridisation mixture was transferred to a second vial with 50 μl of 4 × SSC containing 1.5–3.0 μg ml^{-1} *r* or *l* strand of φ80λ^{imm}d*his*$^+$DNA and 6 mg ml^{-1} of various cold competitor RNAs or *E. coli* tRNA. Hybridisation was continued at 74° C for and additional 7 h. At the end of the incubation, the reaction mixture was diluted with 1.5 ml of 2 × SSC and the DNA-RNA hybrid was collected on a Millipore filter. After treatment with 10 μg RNase A per ml (Worthington) in 2 × SSC at 37° C for 15 min, the filter was dried and counted in a toluene based scintillator.

Under this mechanism, it is clear why all three strains of the class II*B* type regain full expressibility when the barrier against RNA polymerase passage is removed by deletion of the *his01242* region (Table 2). Class II*A* mutations, on the other hand, may affect RNA polymerase binding or both RNA polymerase and positive factor binding. Our values for *in vivo* mRNA production in class II*A* mutants (3–10% in Table 2) are at near-background levels. Sensitive enzyme assays show, in fact, that class II*A* mutants do respond with an increase in enzyme on combination as double mutants with the *his01242* deletion, but they never attain full expression (B. Ely, personal communication).

Attenuator: a common phenomenon?

The above data seem to indicate the presence of a positive factor which binds at the promoter region and exerts its effect downstream on an 'attenuator' region of DNA deleted in *his01242*. The existence of a positive factor-binding mutation in strain *his02966* carrying a mutation located to the right of the presumed RNA polymerase binding site defined by the *his02355* mutation (Fig. 1) makes it likely that the positive factor travels together with RNA polymerase to exert its effect at the attenuator.

The existence of attenuator regions may be a general phenomenon. Extensive deletions in the *E. coli* tryptophan operon that include the region between the operator and the first cistron have a rate of transcription increased two to four-fold *in vivo* for the remaining genes, suggesting that the distal portion of the *trp* operator region limits operon expression[11]. A transcriptional barrier has been detected on λ phage DNA[12]. The *lac* operon might also contain an attenuator which is deleted or altered in UV-5 and similar mutants that exhibit, *in vivo*[13,14] and *in vitro*[15], a reduced requirement for a positive effector protein. In addition each constitutive gene has its own characteristic level of expression, and some constitutive genes are known to be susceptible to 'up-promoter' mutations[16–20]. The existence of an attenuator in certain operons suggests that the potential expressibility of constitutive genes may be much higher and the determination of the constitutive level of expression may be part of the function of the attenuator. A constitutive level of gene expression could either be determined by the base sequence of the attenuator, or by the level of the positive factor. If the DNA sequence of the attenuator solely determines the level of constitutive expression, the necessity of a specific regulatory protein is eliminated.

This model proposes that not only qualitative, but also quantitative information can be coded directly by the

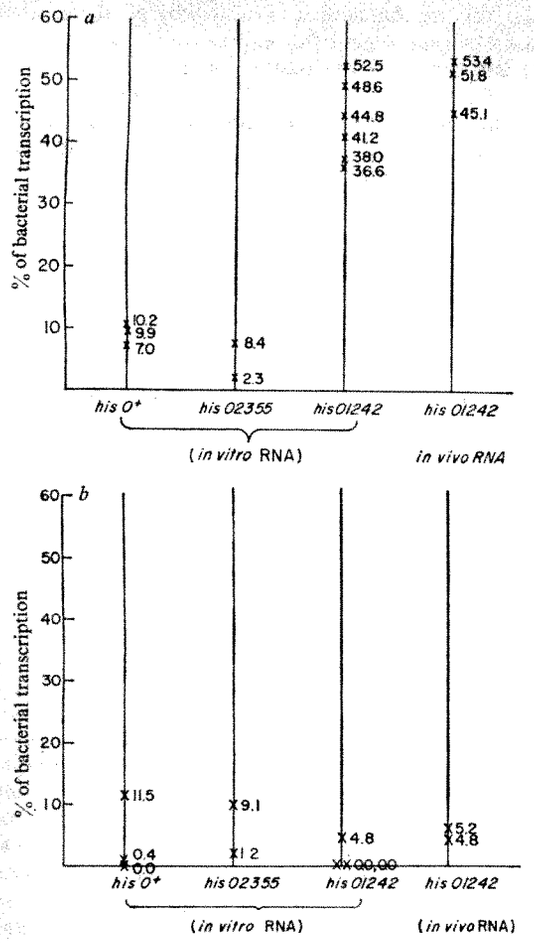

Fig. 3 Level of histidine operon transcription. Individual measurements of the fraction of *his* messenger (*a*) and *his* antimessenger (*b*) in the RNA corresponding to the transduced bacterial segment are plotted with various templates used (*in vitro*) and with the strain *his*01242 (*in vivo*). Methods are described in Tables 1 and 2. *a*, hybridisation to the *r* strand of φ80λ^{imm}-d*his*+DNA; *b*, hybridisation to the *l* strand of φ80λ^{imm}d*his*+DNA

sequence of DNA. Auxiliary protein factors in transcription, positive or negative, may be regarded as means to respond to external information that is superimposed on information built into the DNA polynucleotide sequence. An alternate possibility which is unlikely but is not rigorously excluded is the following. The attenuator could be an RNA chain initiator site (I_1) which requires the positive factor, and I_1 may be followed by a cryptic RNA chain initiation site (I_2) which does not require positive factor. If all RNA polymerase molecules for *his* operon transcription have to travel unidirectionally from the same promoter, the attenuation can be achieved at I_1 by blocking an RNA polymerase molecule which is not accompanied by the positive factor. I_2 may be available for the RNA polymerase only when I_1 is deleted by a deletion such as *his01242*.

Control of *his* operon

I propose that expression of the histidine operon is controlled as follows. Charged His-tRNA, possibly in conjunction with a protein factor, recognises the operon-specific control site on DNA and regulates the binding of a positive factor to the promoter region. This positive factor, in turn, reduces the efficiency of an attenuator which otherwise would limit the frequency of transcription of the operon.

The function of the positive factor as a component of the transcriptional machinery suggests that this molecule is shared by one or more classes of genes, rather than being specific to the *his* operon. Studies of regulatory mutants show that histidine enzyme levels[1] and *his* operon transcription (unpublished results of myself and P. E. Hartman) are regulated by the concentration of His-tRNA. The action of His-tRNA could be effected through interaction with some operon-specific protein such as His-tRNA synthetase[1,21,22] or phosporibosyl-ATP synthetase (EC 421C)[23–26], the target enzyme for feedback inhibition coded by the first cistron of the *his* operon[27–29].

A likely DNA site for the operon-specific control is the most proximal region of the regulatory segment where a large group of constitutive mutations, such as *his01828* (Fig. 1) are located (B. Ely, D. B. Fankhauser and P. E. Hartman, unpublished data). The fact that a single short deletion of the *his01242* region gives rise to full expression makes it unlikely that any dependent negative regulatory mechanism is involved. Thus, the negative control element on the proximal region of the *his* operon probably also exerts its effect through the attenuator. Consequently, it is likely that the binding or action of the positive factor is under the control of the level of His-tRNA. This idea is supported by the observation of a requirement for positive factor-binding site for the expression of a proximally located constitutive mutation, *his01828*. That is, the high enzyme levels elicited by *his01828* are considerably decreased when it is combined in *cis* as a double mutant with a positive factor binding mutation, *his03148* (B. Ely, personal communication).

I thank Dr P. E. Hartman for help, encouragement and for critically reading the manuscript, and B. Ely and H. C. Massey jun. for cooperation. R. P. Goodman, R. A. LaRossa and R. T. Peterson assisted in these experiments. I also thank R. G. Martin and D. Rogerson for growing transducing phages. This work was supported in part by a research grant from the National Institute of Allergy and Infectious Diseases to P. E. Hartman.

UGA and non-triplet suppressor reading of the genetic code

J. F. Atkins* and S. Ryce

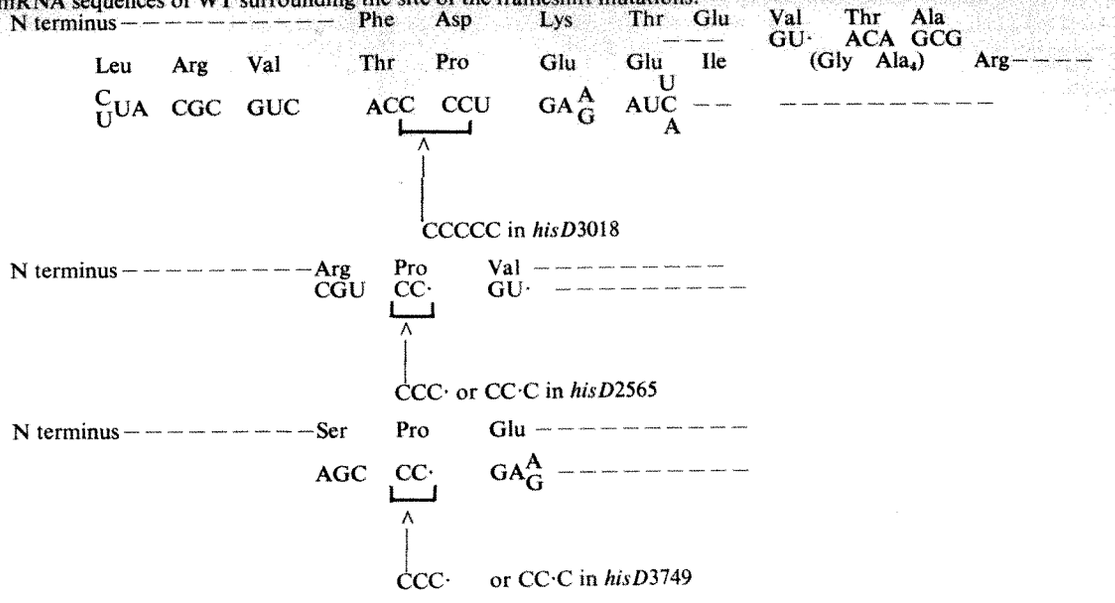
Department of Genetics, Trinity College, Dublin 2, Ireland

Mutants in a tRNA methylase gene, supK, of Salmonella typhimurium *give suppression of UGA and certain frameshift mutants. In addition suppressors which do not suppress UGA, but which suppress frameshift mutants of opposite (effective) signs are described.*

ADDITIONS or deletions of nucleotides in DNA in other than multiples of three are called frameshift mutations and give out-of-phase translation[1]. Analysis of such mutations has shown the triplet nature of the genetic code[2,3], and has helped in the elucidation of the translation termination signals (or barriers) either created by mutational events within genes[4] or naturally occurring at the ends of genes (W. P. Winter, quoted in ref. 5). Analysis of frameshift mutations has also shown the mutagenicity of various environmental chemicals[6]. We have been interested in seeing if single step mutations can give non-triplet reading at certain codons, because of the insight this may provide into the degree of fixation of the present genetic code in having three as the reading unit, and for the new types of alterations of the translation apparatus which may be revealed.

At an early stage it was found that frameshift mutations could be compensated for, or suppressed, by a second insertion/deletion change close to the site of the original mutation such that the wild type reading frame was restored[2,4]. Suppressors of this type are termed intragenic, or internal. More recently it was found that secondary mutations external to the gene in which a frameshift mutation occurs can also specifically suppress many frameshift mutations[7–11]. In three classes of external suppressor mutants there are alterations in the structural genes for tRNA species and another seems to have a defective tRNA-modifying enzyme[15]. In one mutant the frameshift suppressor tRNA has been shown to have an extra base in its anticodon[16]. Of four frameshift mutants which can be externally suppressed, three[12], and probably the fourth[13], have a single base insertion in a region of single base repeats, as shown by amino acid sequence analysis of the altered protein product in intragenic (+-type) revertants. The external suppressor of at least one of these frameshift mutants acts by reading four bases, including the frameshift site, as a codon[14]. Non-triplet reading can also be influenced by certain mutations in the genes for two ribosomal proteins[17].

* Present address: Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724.



In addition to external suppressors which specifically compensate for frameshift mutations, one class of suppressors has been isolated which suppresses both a frameshift mutation, *trpA*91 of *Salmonella typhimurium*[7], and chain-terminating UGA mutations. We report that this class of suppressor mutations occurs in a gene, *supK*, which encodes a tRNA-modifying enzyme[18,11].

Selection of reversions

The prototype of extensively studied +1 frameshift mutants is *S. typhimurium hisD*3018 (ref. 19). It has a +c insertion type frameshift mutation in the region shown in Fig. 1 (refs. 14, 20). The only external suppressors of *hisD*3018 that have been characterised so far insert proline[15,16] at a CCCU codon at the frameshift site. We decided to test whether *hisD*3018 can also be suppressed by certain UGA suppressors as has been shown for *trpA*91. Strains were constructed, each containing *hisD*3018, *trpA*91 and one of three different *lac*UGA mutations borne on episomes of *E. coli* origin. Spontaneous revertants selected at 30° C and 37° C in the three strains for (1) Lac$^+$ (lactose utilisation) His$^+$ (histidine independence), (2) Lac$^+$ Trp$^-$ (tryptophan independence), (3) Trp$^+$ His$^+$, and (4) Lac$^+$ alone. At either temperature there were revertants in each category which showed phenotypic suppression of the unselected marker, and without exception all reversion to Trp$^+$ His$^+$ phenotypically cross-suppressed the lactose mutations.

Other combinations of mutations were tested for simultaneous reversion of the frameshift and nonsense phenotypes and did not reveal any such cross suppression, though it may be found in more extensive tests. The combinations tried were: — *hisC*50 (amber)[21] *trpA*91 (FS[frameshift]); *hisC*117 (ochre)[21] *trpA*91 (FS); *hisD*3018 (FS) *trpA*91 (FS)/F′ *lac*×82 (amber); *hisC*3736 (FS)[22] *trpA*91 (FS)/F′*lac* UGA (three different Z^- alleles); *hisF*3704 (FS)[22] *tprA*91 (FS) /F′ *lac UGA* (three UGA alleles); *trpA*872 (FS) *hisD*3018 (FS) /F′ *lac* UGA (three UGA alleles). Mutation *trpA*872 is an internal suppressor of *trpA*91,[7] and is not itself suppressed by *trpA*91 external suppressors. In addition strains were constructed containing *trpA*91/F′ *lac* UGA and either *hisD*3749 or *hisD*2565 (Fig. 1), known +c frameshift mutations[12]. No cross suppressors were recovered when *hisD*2565 was the histidine marker, but we were not able to obtain unambiguous results when *hisD*3749 was the histidine mutation.

a, Amino acid and mRNA sequences of WT surrounding the site of the frameshift mutations.

b, Map position.

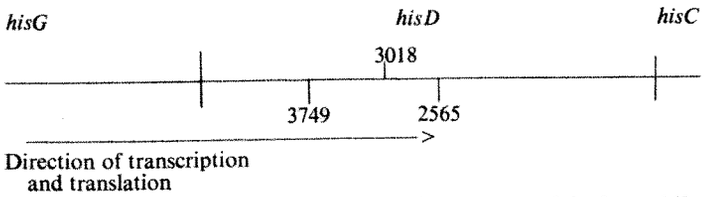


Fig. 1 The nucleotide sequences were deduced from the amino acid sequences of intragenic revertants of the frameshift mutants by Yourno and co-workers[12,14,20]. · Means any base.

Five revertants (nos 610-614) of *hisD*3018*trpA*91/F′*lac*-UGA (Table 1) differing in temperature sensitivity and degree of cross-suppression were selected for further studies. These also had the peculiar property of different abilities to grow on nutrient agar. Since the parent strains grow well at 40° C on nutrient agar, and none of the five revertants do, we selected for back reversions at 40° C on nutrient agar. Revertants with wild type growth rate arose at a frequency of 10^{-8}, and all had simultaneously lost the His$^+$, Trp$^+$ and Lac$^+$ phenotypes as well as their temperature sensitivity. This strongly suggested that all four phenotypic characteristics may be due to a single suppressor-generating mutation. The five revertants (610-614) were then designated *sup*−610 to −614.

Mapping suppressors

Preliminary mapping of *sup*610 to 614 indicated a location in the *argB metK* region. The mutations were further mapped by transduction methods similar to those used previously[7] with P22 or its variants H4 or L4 (ref. 23). The recipients were *hisD*3018 *trpA*91 *pro*−438 *sup*$^+$ (alleles 610–614) /F′ *pro*$^+$ *lac*UGA and the donor phage was grown on *his*C3072 *trpA*91 *leu*-1132 *serA*790 *lys*-554 *sup*$^-$. *sup*$^-$ transductants were selected at 40° C on nutrient agar, approximately 20% of the *sup*$^-$ recombinants were Ser$^-$ Lys$^+$ and 8.5% Ser$^+$ Lys$^-$. Reciprocal transductions with selection for Lys$^+$ and scoring for His$^+$ Trp$^+$ Lac$^+$ and t^s were plated at 30° C and gave consistent results. The suppression and temperature sensitivity characteristics were not separable, thus confirming that in each strain a single mutation was responsible for the pleiotropy. *serA* and *lys* are not cotransducible but the suppressor gene is cotransducible with either marker. Both a dominant frameshift suppressor, *sufD* (ref. 22), and a recessive UGA suppressor, *supK* (ref. 18), have been located in this region between *serA* and *lys*. Derivatives of the *sup*$^+$ (that is, suppressor containing) strains were constructed which were cured of the *F′pro*$^+$*lac*$^-$ episomes, and had the genotypes *hisD*3018 *trpA*91 *serA*790 *sup*$^+$ in their genomes. The strains were infected with the *E. coli* F prime KLF_{16} carrying *serA*$^+$*supK*$^-$*sufD*521*lys*$^+$ with selection for *ser*$^+$. *sufD*52 does not suppress *hisD*3018 or *trpA*91. The F′ ductants were all His$^-$ Trp$^-$ and not t^s. Curing the strains of KLF_{16} restored the His$^+$ Trp$^+$ and t^s characteristic of each strain, thus demonstrating recessivity of the suppressors 610 to 614. This recessivity shows non identity with *sufD*, and is consistent with their being *supK* mutants. Identity with *supK* was confirmed when previously characterised *supK* mutants −584, −1175, and −1176 (ref. 18)

Table 1 Temperature sensitivity and phenotypic suppression characteristics of five His+ Trp+ Lac+ reversions

Phenotypically His+ Trp+ Lac+ Revertants	Phenotype selected originally	Temperature of selection	Growth on nutrient agar at 30° C	at 37° C	at 40° C	Phenotypic suppression of Lac	His	Trp
610	Lac+ Trp+	30° C	Yes	No	No	+++	+	+
611	Lac+ Trp+	30° C	Yes	Yes	No	+++	++	+++
612	His+ Trp+	37° C	Yes	No	No	++	+	+
613	Lac+ His+	37° C	Yes	Yes	No	+++	++	±
614	Lac+	30° C	No	No	No	+	+	+
Parent strains of revertants 610–614			Yes	Yes	Yes	—	—	—

*hisD*3018 *trpA*91 *pro*-438/F′*pro*$^+$*lac*$^-$ UGA (three different UGA alleles)

Strain construction methods were analogous to those described previously[7]. The *pro* mutation was of spontaneous origin and was used to hold in the episome by omitting proline from the medium. The strains were not exposed to any mutagen. All strains were *str*^{s}. +++; single colonies (> 1 mm diameter) in 48 h at the optimum temperature. We estimate +++ as 5–10% efficient based on our own assays of anthranilate synthetase, and comparison with *sup*-584 (see below and ref. 18) for *lac* supression. *F′ pro*+ *lac* UGA were from strains TR289, 294 and 341.

showed similar frameshift and UGA suppression characteristics when cotransduced with *serA* into *his*3018*trpA*91 strains carrying *F'lac*$^-$ *UGA* episome.

Models for *supK* suppression

Cross suppression between UGA and another triplet (UAA) has previously been reported[24,25] but the suppression of UGA and certain frameshift mutations described here is novel. Can these results be explained without invoking non-triplet reading?

One model in which during translation the fidelity of triplet reading may be maintained while at the same time the effect of a frameshift mutation is suppressed is as follows. A frameshift mutation may generate several nonsense codons in the new phase in an mRNA message. Normally the ribosomes do not continue translating the message beyond the first nonsense codon unless either of two conditions are fulfilled: (1) a suitable suppressor for this first nonsense is present in the cell; (2) an internal initiator codon is available in close vicinity. This initiation may be in the neutral, that is, wild-type phase.

Fulfilment of condition (1) at the first nonsense and (2) at the encounter of the second nonsense, if this nonsense is different from the first, would result in the reversal of the effect of a frameshift mutation while maintaining triplet reading. Two polypeptide fragments are then produced.

This model can be applied to suppression of *trpA*91 and *hisD*3018 by the UGA suppressor, *supK* by assuming UGA as the first out of phase nonsense (see Fig. 1) and either UAA or UAG as the second encountered nonsense. Complementation of the two fragments could then give active enzyme. An alternative version of this model, which could lead to the production of overlapping fragments which might be joined into full length polypeptide chains[26], was discussed earlier[7]. Since in both versions of this model the amino acid sequence in the region between the frameshift and the end of the first fragment is unimportant, any amino acid inserted by a UGA suppressor is likely to be acceptable at the UGA site and lead to suppression of the frameshift mutants. We tested three alleles of *supS*, a strong dominant UGA suppressor[27], in partial diploid strains *trpA*91*hisD* 3018*ile*$^-$ *supS*$^-$ /*F* $_{13}$*met*$^+$*ile*$^+$*supS*$^+$ and found no suppression of either frameshift. In addition in an earlier test no internal reinitiation, as detectable by complementation with the available mutants, was found in *hisD* (ref. 28). We therefore favour models in which the suppression of frameshift mutations involves non-triplet reading.

One possibility is that the non-triplet reading occurs not at the frameshift site but at the first nonsense codon encountered thereafter in the out of phase frame, for example UGA· (where · means any base). This could be ruled out if a frameshift which has an amber or ochre as the first downstream out of phase nonsense codon, is suppressed by *supK* suppressors. With the available strains *hisD*3749 and *hisD*2565 we were unable to test this model conclusively (see above).

Alternatively suppression of the frameshift mutants may occur by non-triplet reading close to the frameshift sites. In *supK* mutant strains tRNA is undermethylated and more than one species of tRNA may be affected. The defective modification of one species of tRNA enables it to read the triplet UGA, and of a different species may allow it to read a non-triplet as a codon. It is possible that other components of the translation machinery are undermethylated in *supK* mutants, and may be causing the non-triplet reading. This is, however, unlikely in view of the specificity of the tRNA methylases which have been examined[29]. It is known that *hisD*3018 is a +1 frameshift so presumably its suppression is by quadruplet reading. The sign of *trpA*91 is unknown but the most likely possibilities are that its suppression is by quadruplet or quintuplet reading in *supK* mutant strains (see below).

We find a class of external suppressors for *trpA*91 which are in a gene other than *supK* and which do not also suppress UGA. External suppressors for *trpA*872 have also been isolated. These too are not in the *supK* gene and do not in addition suppress UGA. Since *trpA*91 and *trpA*872 are compensatory frameshift mutants[7], one must be read as a quadruplet and the other may be read as a quintuplet, or possibly as a doublet. A doublet seems unlikely because of the amount of general misreading a doublet suppressor presumably would generate. The reading of four, twice, close to each other to correct the reading is probably only a theoretical possibility in view of the very low efficiency which would be expected. Other types of experiments may have some relevance to how this type of suppression may occur. A ribosome binding experiment gave no evidence for the nature of the adjacent base affecting triplet codon anticodon interaction[30]. But equilibrium dialysis experiments between pentamer oligonucleotides and wild type tRNA show that wild type tRNA does have weak binding to the fifth base (ref. 31 and O. C. Uhelenbeck, personal communication) as well as to the fourth[32]. Presumably a change outside the anticodon loop could make this binding more efficient. This would then be analogous to the situation with the first UGA suppressor tRNA sequenced[33]. But on the basis of the high degree of leakiness of UGA mutants[34,35] compared with that found with the frameshift mutants which have been examined[17], and other considerations it seems more likely that the suppressor activity is due to an insertion in the tRNA anticodon itself.

The study of frameshift mutants in bacteria was initiated when a frameshift specific mutagen, ICR191 an acridine derivative, was found for bacteria[21]. The six frameshift external suppressors which have been characterised in most detail, *sufA–F* suppress frameshift mutations which arose after ICR 191 mutagenesis[22]. *trpA*91 was however isolated after X irradiation and *trpA*872 is of spontaneous origin, and the external suppressors for *trpA*91 and *trpA*872 are in classes which are clearly different (S. R., unpublished) from *sufA–F*. This then raises the possibility that several additional frameshift suppressor classes can be isolated.

We thank J. R. Roth for providing many bacterial strains, L. Soll, J. C. Loper, and G. W. P. Dawson for helpful comments, H. J. Creech, Institute of Cancer Research, for a gift of ICR 191, and B. McTiernan for technical assistance. This work was supported by a grant from the National Science Council of Ireland.

Narrow-band observations of galactic and extragalactic sources at 1 mm

We report the result of a search for discrete extragalactic sources of continuum radiation near 1.2 mm. The observations were made during a run of one week on the United States National Radio Astronomy Observatory (NRAO) 11-m telescope at Kitt Peak, Arizona.

We attempted observations of a total of 90 known extragalactic objects: three were probably detected (3C84, 3C120, 3C273) and two were possibly detected (3C345, 0727–11). These five objects comprise two quasars, a Seyfert galaxy, an N galaxy and an unidentified radio source. In each case the millimetre emission represents a substantial fraction of the total power of the object, and for 3C120 and 3C345 it may well exceed the power at all other known wavelengths. We also observed a number of well known galactic regions and found millimetre emission in several of them. A detailed description of the observational techniques and discussion of some of the theoretical implications of these observations will be given elsewhere.

Table 1 Probable detections

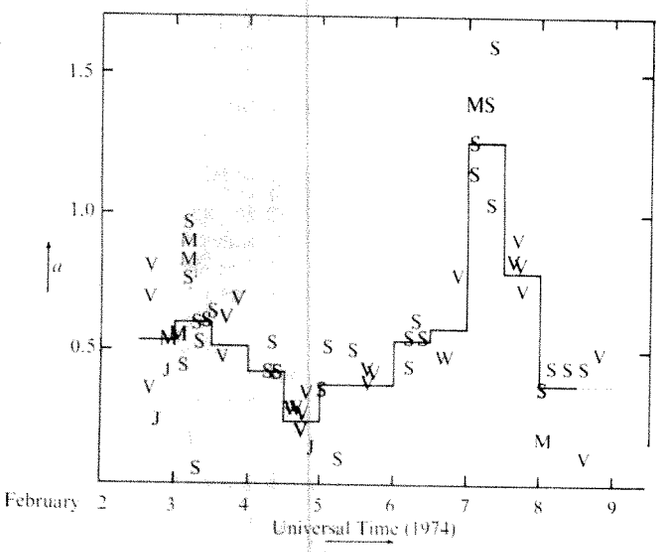

Fig. 1 Atmospheric attenuation coefficient, a, as a function of time during our observing run, from observations of the planets Venus (V), Mars (M), Saturn (S) and Jupiter (J).

In order to study as many types of object as possible, our observing list included: (*a*) all 3C quasars; (*b*) all 3C radio galaxies with $z \leq 0.02$; (*c*) all known Seyfert galaxies with NGC or Markarian numbers and $\delta \geq -2°$; (*d*) all known N galaxies; (*e*) all QSOs with $z \leq 0.2$ in the Braccesi and Formiggini list[1] of optically selected blue stellar objects; (*f*) all known radio sources with $|b| > 10°$ satisfying one or both of the criteria S(1 cm) $\geq$ 4 f.u., S(3 mm) $\geq$ 2 f.u.; (*g*) all galaxies brighter than 11 mag (m_{pg}) with $\delta \geq -2°$; (*h*) all infrared galaxies with S(10 μm) $\geq$ 0.1 f.u., $m_{pg} \leq 12$; (*i*) all galactic radio sources with S(6 cm) $\geq$ 30 f.u. and diameter $\leq 6'$—a total of over 200 objects. Several experimental limitations and problems prevented us from observing more than about half of this list, namely: the location of the Sun; the inability of the telescope to look within 90° of a wind in excess of 20 mile h^{-1} (three nights of our run); intermittent unstable behaviour of the detector/amplifier system; bugs in the computer software. In spite of the resulting selection effects we believe that the sources we observed are a representative sample of the main types of known extragalactic object.

Most of the sources were observed for between 10 and 20 min. A smaller group of 25 sources, comprising the nearest objects in each of the above categories (*a*) – (*h*), together with several radio sources with strong, variable, flat-spectrum emission at high radio frequencies, were observed for between 30 min and 3 h.

We used the NRAO 1-mm continuum receiver (J. D. G. Rather, P.A.R.A., and P. E. C. to be published), beam-switched over 130″. The radiation is detected by a three-part, scandium-doped, germanium bolometer[2]. With its standard low pass filters, this receiver has a response extending from 800 μm to 3 mm. Imperfections in the dish surface act as an additional low pass filter; at 250 GHz, the aperture efficiency is about 12% for an unpolarised feed (the 1-mm receiver is partially polarised). The overall bandpass of the standard filters, atmosphere and telescope will be published elsewhere. Because this bandpass is so large, the mean wavelength depends strongly on the spectral index of the source[3]. For this reason, we used additional filters to restrict the bandwidth. With these filters, the mean wavelength should be close to 1.2 mm for any reasonable spectral index. Thus our observations are the first of extragalactic sources that can genuinely be described as giving narrow band fluxes close to 1 mm (see ref. 4 for line observations of galactic sources at 1.3 mm). For comparison, some sources were observed with only the standard broadband filtering.

We determined the flux scale for the sources, and the attenuation of the atmosphere, by making frequent observations of the planets. Planetary fluxes were computed from the temperatures given by Rather[3], which we believe to be correct to 10%. Venus and Jupiter had to be observed through the wall of the dome, the transmission of which we measured to be 40%. We assumed the attenuation of the atmosphere to be given by $\exp(-a \sec z)$ where z is the zenith distance and a is a function of time. This would be true for monochromatic observations through a plane-stratified atmosphere, and we found this simple model to be a reasonable approximation.

Figure 1 shows how a varied with time during our run, measured from 61 planetary observations taken at different elevations each day. The sudden decrease in transparency on the night of February 7 was due to the arrival of a front, accompanied by light cloud, and shows the importance of frequent calibration at these wavelengths. The solid line shows the mean values of a for 12-h intervals, which we have used in the present preliminary analysis.

The lists of our probable ($\geq 3.5\sigma$) and possible (2.5 to 3.5σ) detections are given in Tables 1 and 2. The few broadband observations we made, and the results of earlier broadband measurements by Ade, Rather and Clegg in February 1973 (previously unpublished) are also shown. The data from each of the several scans on each object were converted to a flux density and corrected by the appropriate attenuation factor, before being combined into an r.m.s. error-weighted mean. ($\overline{S} = (\sum_i S_i/\sigma_i^2)\sigma^2$ where $\sigma^{-2} = \sum_i \sigma_i^{-2}$ and S_i, σ_i are the mean and standard error for an individual scan). A histogram of $\overline{S}/\sigma$ is shown in Fig. 2 for all our observations: apart from the excess of points with $\overline{S}/\sigma \geq 2.5$ the histogram agrees well with the expected Gaussian distribution, indicating that there are no gross systematic errors present. We are confident that the majority of the sources with $\overline{S} \geq 2.5\sigma$ are genuine detections.

Table 3 lists the sources from which no radiation was detected.

Schematic radio, millimetre, infrared and optical spectra have been compiled from the literature for six extragalactic objects (Fig. 3). The Parkes source 0727-11 is at present unidentified: its proximity to the galactic plane means that a galactic origin cannot be ruled out. Although discussion of these spectra must await a more thorough determination of our flux-density scale and effective wavelength, the impression is that we are seeing a similar phenomenon in most of the objects, namely a flux-density rising steeply with frequency in the millimetre region. The fact that 3C273 is the nearest known quasar (this is probably true even if its redshift is not cosmological) and that 3C120 is the nearest N galaxy (it has also been classified as a Seyfert[7] and as an N-type Seyfert[8]) suggests that strong millimetre emission may be a common property among galaxies with active nuclei. (The flux measured from the nearest Seyfert galaxy NGC4051 was 28 ± 12 f.u., on the brink of detectability.) The corresponding millimetre luminosities cannot be determined without more reliable spectral information, but they will be of order

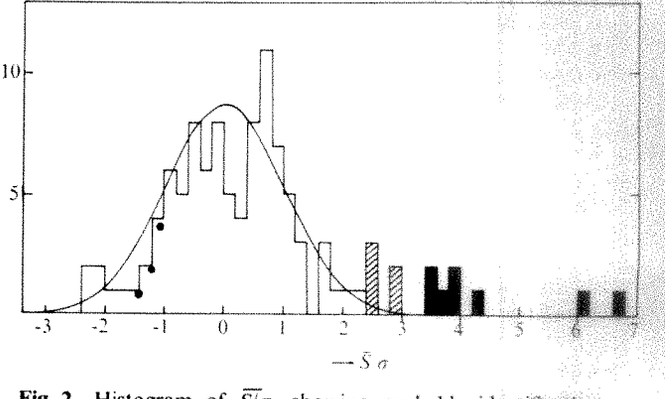

Fig. 2 Histogram of $\overline{S}/\sigma$, showing probable identifications (heavy shading), and possible identifications (light shading).

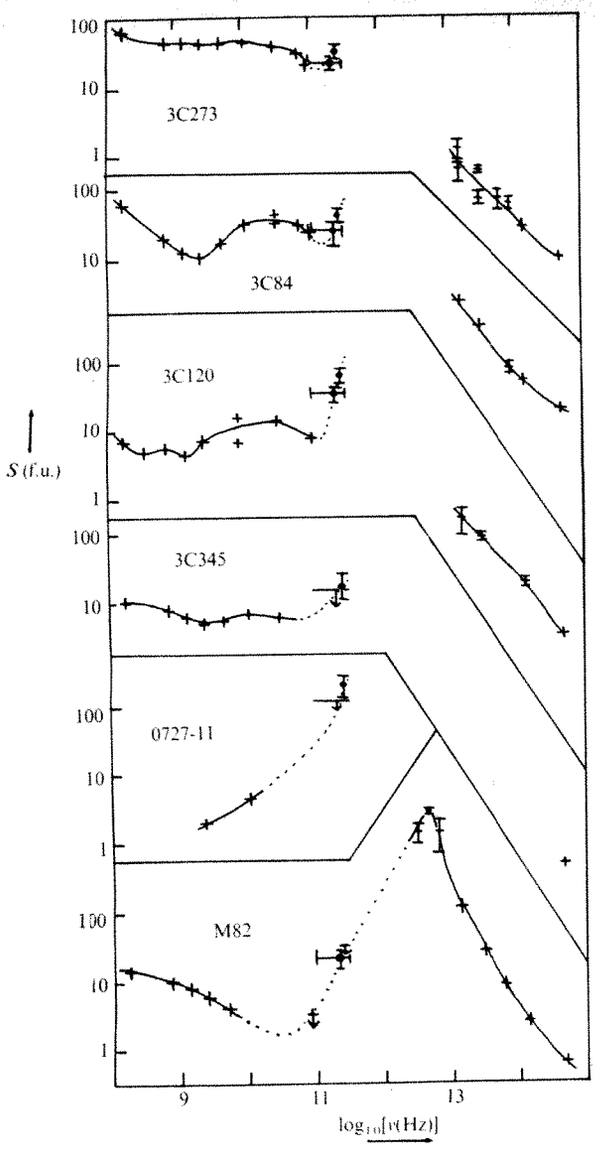

Fig. 3 Schematic radio, millimetre, infrared and optical spectra for detected extragalactic sources. Filled circle with vertical bar, present observations at 1.2 mm; circle with vertical and horizontal bars, broadband.

$P(\nu).\nu$, where $P(\nu)$ is the monochromatic luminosity, and at 1.2 mm, this quantity ranges from $\sim 10^{41}$ erg s^{-1} for M82 to $\sim 10^{47}$ erg s^{-1} for 3C345 if its redshift is cosmological.

The possible detection of the nearby spiral galaxy M81 is extremely surprising, since there is no other optical peculiarity which would explain why it should have a millimetre luminosity more than 10^4 times greater than our own galactic centre. This observation should be treated with caution until a less marginal detection can be achieved.

We stress that the flux densities quoted here are preliminary, although we do not expect the flux scale to be in error by more than 25%. We also emphasise that the search we have made is in no sense complete down to some flux level, owing to the strong dependence of the atmospheric attenuation on zenith distance and time. But among the objects mentioned in this paper, we doubt if we have missed any sources brighter than 200 f.u.

We thank the NRAO for time on the telescope, and for support facilities. The staff of NRAO, Arizona, provided assistance. The NRAO is operated by Associated Universities, Inc. under contract with the National Science Foundation. We also thank the Science Research Council for support (P.E.C. & M.R-R) and for a Research Fellowship (P.A.R.A.).

Queen Mary College, University of London, Mile End Road, London E1, UK

Received February 26; revised March 25, 1974.

Note added in proof: Reanalysis of the spectral response of the detector system suggests that the mean effective wavelength for our narrow band observations may be closer to 1.4 mm than 1.2 mm. If this is confirmed, the flux densities in Tables 1–3 need to be reduced by 25%.

Spontaneous fission on the Ap star HR465

There is an anomalously high abundance of heavy elements on the Cr-Eu subgroup on the Ap star HR465 (refs 1–3). The overall abundance pattern of elements with $Z \gtrsim 40$ indicates that the heavy elements originate from *r*-process nucleosynthesis[3]. In the *r*-process abundance curve there is a broad peak in the rare earth region centred around $Z \simeq 65$ ($A \simeq 165$). The rare earth elements on HR465, however, produce a peak centring near neodymium and samarium at $Z = 60 \sim 62$ (ref. 3); this clearly differs from the trend of the *r*-abundance pattern. Nor does the rare earth peak on HR465 correspond to the *s*-process abundance peak around barium and lanthanum ($A = 135 \sim 140$). Moreover the amount of barium on this star is too small to produce this rare earth peak by the local *r*-process, which begins from the *s*-process peak of barium and lanthanum[4]. Other explanations for the overabundance of rare earth elements on Ap stars do not seem appropriate for HR465 (ref. 1). I examine here an alternative possibility—that the rare earth anomaly on HR465 originates from asymmetric spontaneous fission.

According to the liquid drop model of fission[5], the mass number M_H of the heavy fission fragment produced by the asymmetric spontaneous fission of nuclide (Z, A) is given by

$$M_H = 0.5\,(A - \bar{\nu}) + 0.045A\,(40.2 - (Z^2/A))^{1/2} \qquad (1)$$

where Z^2/A must be less than 40.2, and $\bar{\nu}$ is the average number of prompt neutron per fission event. The $\bar{\nu}$ depends on the excitation energy of fission fragments, but it is approximately given by

$$\bar{\nu} = 0.117A - 25.73 \qquad (2)$$

The numerical coefficients in equation (2) were determined by the least-squares method using the experimental values[6] of $\bar{\nu}$ for spontaneous fission.

The nuclides with $A \gtrsim 180$ can be produced in the Universe only by the *r* process. In the period of *r*-process cooling, delayed spontaneous fission would occur during the successive β decays. Using the value 1.78 for the surface asymmetry constant κ in the expression for the surface energy of a spherical nucleus, implies that all the nuclides in the range $A \gtrsim 265$ ($Z \gtrsim 96$) (ref. 7) would completely disappear in the neutron-rich region far from the β-stability line, because of delayed spontaneous fission with $\lambda_{sf} > > \lambda_\beta$. ($\lambda_x$ is the decay rate of the mode x). As for the nuclides with $250 \lesssim A \lesssim 265$, they become unstable against spontaneous fission faster than they become α-unstable with the approach of the nuclides to the β-stability

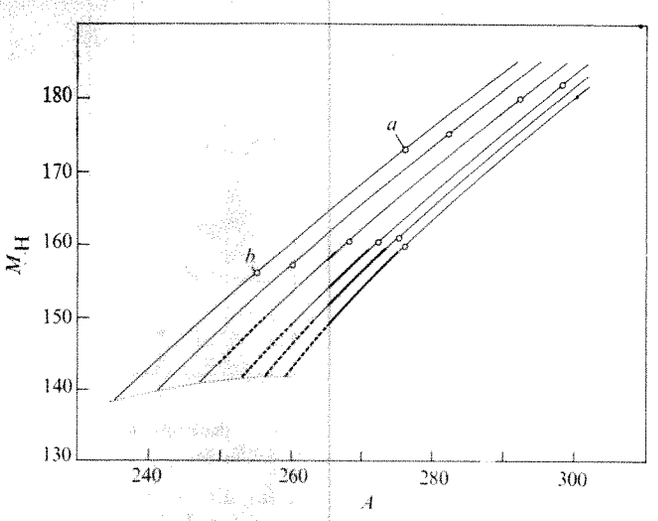

Fig. 1 Mass number M_H of the heavy fragment from the asymmetric spontaneous fission of nuclide (Z, A). Heavy solid lines and heavy dashed lines represent, respectively, the regions for delayed spontaneous fission[7] and regions unstable against spontaneous fission[8]. Small open circles indicate the nearest nearby nuclides to: *a*, Q_n=MeV; *b*, Q_n=4 MeV. . . . . , β-stability line. From left to right, the six curves correspond to: Z=92; Z=94; Z=96; Z=98; Z=99; Z=100.

line ($\lambda_{sf} > > \lambda_\alpha$) (ref. 8). So they would fission completely on the neutron-rich side near the β-stability line. On the other hand, the nuclides with $A \lesssim 250$ can reach the β-stability line safely (see Fig. 1).

The β-stability line was deduced from the relation $Z = (0.3A + 100)A/(A+200)$ (ref. 9) and the nuclides closest to $Q_n = 2$ and 4 MeV are denoted by small open circles. Here Q_n is the binding energy[10] for the last neutron in the nuclide (Z, A), and the *r* process usually proceeds through the neutron-rich nuclides with $Q_n = 2 \sim 4$ MeV (ref. 11). The maximum atomic number attainable on the *r*-process neutron capture path under $Q_n = 2 \sim 4$ MeV is $98 \sim 100$ (refs 7 and 12). The *r*-process cooling takes place from the neutron-rich region of $Q_n = 2 \sim 4$ MeV in the direction of increasing Z, keeping the mass number A constant (vertically downward in Fig. 1). If we adopt $\kappa = 1.78$, the nuclides heavier than 265 completely disintegrate by delayed spontaneous fission in the early period of the cooling to form the abundance peak of heavy fission fragments at around $A = 155 \sim 160$. Almost all the nuclides in the range $250 \lesssim A \lesssim 265$ undergo spontaneous fission in the later period of the cooling and all their fission fragments accumulate around $A = 145 \sim 150$. The Nd-Sm abundance peak on HR465 is situated at $A = 145 \sim 150$; the position of this peak just corresponds to the heavy fragment peak from the spontaneous fission of *r* nuclides with $250 \lesssim A \lesssim 265$. This indicates the possibility of a spontaneous fission origin for the Nd-Sm peak.

In 1960 the measured abundances of these elements on HR465 were Nd≃Sm≃10^6 (ref. 1). I shall express the abundance of elements in a scale of H=10^{12}. To produce the Nd-Sm peak by the spontaneous fission of the nuclides in $250 \lesssim A \lesssim 265$, the average abundance produced, N_1, corresponding to each mass number in the range $250 \lesssim A \lesssim 265$ must be

$$N_1 \simeq 10^6/(Y(265-250)) = 10^6 \quad (3)$$

where Y (≃0.07) represents the fission yield at the heavy fragment peak when the total fission yield is set equal to 2.

The abundance of uranium on HR465 is about 3.5×10^5 (ref. 2). Although we do not have information on the age of this star, the life of main sequence Ap stars is, in general, 10^8 to 10^9 yr. The isotope ^{238}U (4.51×10^9 yr half life) is, therefore, likely to survive almost completely, but the existence of ^{235}U (7.1×10^8 yr half life) is not likely. The numbers of alpha-radioactive precursors for ^{238}U and ^{235}U (including those nuclei) are 3 and 6, respectively[8]. So the range of the average abundance N_2 of the nuclides produced in the range $A \lesssim 250$ is given as follows, assuming two extreme cases of the complete survival and the complete extinction of ^{235}U:

$$3.5 \times 10^5/(3+6) = 4 \times 10^4 < N_2 < 3.5 \times 10^5/3 = 1.2 \times 10^5 \quad (4)$$

From equations (3) and (4), the *r* nuclides with $250 \lesssim A \lesssim 265$ must be produced with abundance higher than that of the nuclides with $A \lesssim 250$ by a factor of 8 to 25.

The abundance peaks of the *r* nuclides at $A \simeq 130$ and 195 correspond to the neutron magic numbers of $N=82$ and 126, respectively. The abundance of the nuclides situated on these peaks is greater than the background abundance by a factor 10 to $10^{3/2}$. Although a precise estimate of the next neutron magic number or submagic number after $N=126$ is difficult at present, $N=164$ (ref. 13) or $N=170$ (ref. 14) have been proposed. If the *r*-process proceeds through the path of $Q_n=3$ MeV, the abundance (sub)peak due to the neutron (sub)magic number would be formed at around $A=250 \sim 252$ when we adopt $N=164$ as a neutron (sub)magic number, and at around $A=258 \sim 260$ when we adopt $N=170$. These peak positions were estimated by using the mass table presented by Seeger and Perisho[10]. In any case the *r*-process make an abundance (sub) peak in the region $250 \lesssim A \lesssim 265$. So the produced abundance of the nuclides in the region $250 \lesssim A \lesssim 265$ would be expected to be higher than that in $A \lesssim 250$ by about a factor 10 to $10^{3/2}$. This explains the high abundance ratio N_1/N_2.

Thus the overabundance in the rare earth region centred near neodymium and samarium can be explained by the asymmetric spontaneous fission of *r* nuclides with $250 \lesssim A \lesssim 265$, which takes place in the later period of the *r*-process cooling. In this case the mass number M_L ($=A-\bar{\nu}-M_H$) of the light fragment from the spontaneous fission is broadly distributed in the range $103 \lesssim M_L \lesssim 112$. Elements such as Rh, Pd, Ag, Cd and In ($Z=45 \sim 49$) are situated in this mass region, and each element is estimated to have the high abundance of at least $\sim 10^6/5 = 2 \times 10^5$. In fact the abundance of palladium on HR465 is extremely high[3]. The abundance determination of Rh, Ag, Cd or In is needed for the more affirmative conclusion for the spontaneous fission origin of the rare-earth peak on HR465. Furthermore we can also expect the high abundance of lead and bismuth on this star since they are the final stable elements of radioactive decay chains in $A \gtrsim 210$.

There are some peculiar A stars which have anomalously high abundances of thorium and uranium[15-18]. An abundance peak centred near neodymium and samarium similar to that on HR465 may be observed also on these Ap stars.

Copernicus spectra of β Lyrae

WE have observed the far ultraviolet spectrum of β Lyrae using the Princeton spectrometer, on the Copernicus satellite[1]. The principal data were scans in the low resolution mode (0.2 Å in the (U2) region 1,000–1,500 Å and 0.4 Å in the (V2) region 2,000–2,900 Å) at phases nearly coincident with the two light minima. Shorter scans (1,100–1,300 Å) were obtained at the two quadrature phases. All observations were made in August and September 1973 but not in the same orbital cycle.

The highest signal-to-noise ratio was obtained in the region 1,000 to 1,300 Å (Fig. 1). Beyond 1,300 Å the instrument response falls rapidly and only the strongest spectral features were detectable. In the longer wavelength region, the signal-to-noise ratio is considerably lower because of high background particle counts; here too, only major spectral features were identifiable.

The spectrum is spectacularly different from B8, the classification given in the visible region. Copernicus scans of normal stars later than about B2 show a rich absorption spectrum, particularly for those of high luminosity. The far ultraviolet spectrum of β Lyrae contains many emission lines, some with P Cygni-type profiles, some of very high excitation, but none with radial velocities associating them with the primary B8 star. It seems that the spectrum in this region is predominantly from a hotter source than the visible primary, supporting several recent suggestions[2–5] that the secondary component in β Lyrae is the hotter object. The recently revived[6] idea of an F-type secondary seems to be eliminated.

A few absorption lines corresponding to the B8 spectrum are observed longwards of 2,400 Å. Multiplet 1 of FeII is present completely in absorption, and estimates of its velocity indicate an amplitude (in phase with the B8 spectrum) of 340 km s^{-1}. The primary star velocity amplitude from the ground based data is 370 km s^{-1} (ref. 7). The strongest transitions from the excited levels of SiIII and SIII are also seen in absorption in this part of the spectrum, with a velocity range of 380 km s^{-1}.

The far ultraviolet spectrum is unique among those so far observed by Copernicus in the number and strength of emission lines. Some 50 are definitely identified; an equal or greater number remains in doubt because of blending effects, or low instrumental response. Figure 1 illustrates a region of the spectrum fairly free of overlap; profiles range from classical P Cygni-type to those which resemble more a broad emission seen on both sides of a shortward-shifted central absorption. (This latter type of profile is also seen at Ha, ref. 8). These profiles are typical of a rotating, outward moving envelope with expansion velocities of ~ 150 km s^{-1} (see refs 9 and 10). A rapidly rotating hot secondary with an outward moving envelope (in its equatorial regions), or an expanding shell around the system, is suggested.

A small velocity variation is found in the absorption and emission turning points of these profiles. In Table 1 we give the mean values derived from some 15 features which are thought to be free of blending effects. These velocity values are similar to those of the shell absorptions and emission peaks in the visible spectrum[7] at, for example, Hγ or HeI 3,889.

These numbers presumably do not represent the motion of the secondary alone, and probably are affected by mass exchange and other motions within the system.

The continuum is generally confused by overlapping emission, but its position may be estimated at 1,220, 1,150, 1,300 and 1,100 Å, in decreasing order of certainty. The flux levels, corresponding to a mean wavelength of 1,200 Å are given in Table 2.

These figures are in good agreement with the turning points of the OAO-2 light curves[2]. They show that the quadratures have unequal light and that the secondary

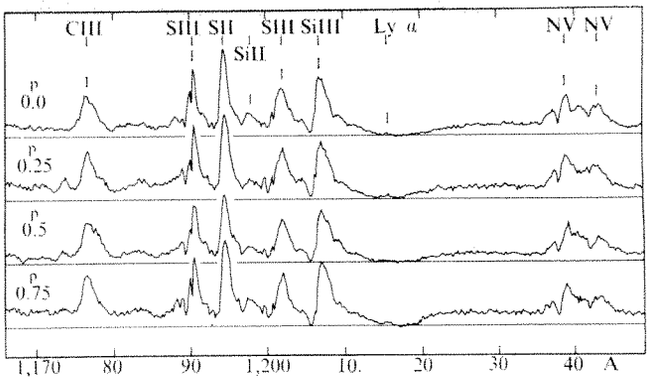

Fig. 1 Portions of Copernicus OAO spectrum scans of β Lyrae at four orbital phases.

minimum is the deeper one in the far ultraviolet. This is in keeping with the evidence that the hot radiation associated with the secondary dominates this part of the spectrum.

The emission lines do not show any marked eclipse effects. But changes are indicated in the absolute peak intensity of some lines and these are generally in the sense of being stronger than normal (by about 30%) at phase 0.0. This is comparable with the continuum changes, and evidence that the emission lines are not associated with the primary.

Table 3 summarises the strong line features indentified. The Lyman lines are very broad (>10 Å), go to zero central intensity and are the only features without emission. They are similar to the Lyman lines seen in other Copernicus data and are presumably interstellar and/or circumstellar.

Helium is not conspicuous; the λ1,085 feature may be ascribed either to HeII or a close resonance multiplet of NII. The feature is strong (peak intensity 8 to 10 times continuum) and complex, so it may be a blend.

The NII and CII lines in the V2 region showing stellar absorption velocities come from excited multiplets. The emission in the U2 region of CII and CIII (and NII if it is present at 1,085 Å) are from zero excitation multiplets.

The most important features are the NV lines, which indicate very high excitation. The presence of these lines was suspected by Houck[11], who found a variable emission redward of Ly α on OAO-A low resolution scans. But he favoured the interpretations at Ly α emission, because of the high excitation of NV. Our data do not display the strong phase variation of these features found by Houck; a nonperiodic change in the system may be indicated. In our data, the profiles and velocities of the NV lines differ somewhat from those of most other lines, so that the features may originate in a different part of the system.

There is no definite evidence for the presence of other lines of high excitation. No lines of NIV, CIV, OIV, or OV lie in the well observed region of the spectrum. There is an OVI line at 1,032 Å, and although a line is seen at this wavelength, there is no sign of the other component of the resonance doublet at 1,037 Å. The 1,032 Å line can be attributed to FeIII.

The Si and S lines identified are all strong features (Fig. 1). Stellar absorption components of SiII and SiIII are suspected in the V2 region. A broad emission at 1,344 Å may be the PIII (1) resonance triplet.

The spectrum of FeIII is strong and all multiplets from 1 to 59 are seen, when their lines are suitably located. The spectrum is unusual in emission in stellar spectra, and it is interesting that P Cygni itself shows FeIII emission in the visual and photographic spectral regions.

Table 1 Mean line radial velocities

Phase	0.0	0.25	0.5	0.75
Absorption (km s^{-1})	−175	−125	−140	−135
Emission (km s^{-1})	105	165	150	160

The spectrum of FeII is very rich in the observed region, but is not definitely present in our data. Lines of FeII (primary absorption) are seen in the V2 region. The presence of other iron peak ions (TiIII, IV, CrIII, MnII, III) is possible, but not certain, primarily because of blending with FeIII.

What do these observations tell us of the nature of the secondary component of β Lyrae? There is little doubt that it is a hotter object than the visible B8 star, from the presence of high temperature lines and continuum, whose velocities and intensities do not follow the behaviour of the visible primary star. The velocity amplitude of the lines suggests that the secondary is the more massive object, by a factor of several times. But, it is evident that the observed line features originate in an extended region around the secondary, which may be highly rotating, and expanding in its outer layers.

Table 2 Continuum light level at 1,200 Å

Phase	0.0	0.25	0.5	0.75
Light	0.81	1.00	0.75	1.10

The spectrum of the massive secondary is invisible in the terrestrial spectrum, either because it is shielded by the extended envelope, or because the B8 star is overluminous. The latter possibility is a strong one if the system is near the end of case B mass exchange. The system would then be rather similar to the Algot-type semidetached eclipsing binaries, and its evolutionary history would be simple. A model of this type was proposed by Kriz[4], using the computations of Kippenhahn and Weigert[12], and more recently by J. Ziolkowski (unpublished). But overall consistency in mass, luminosity, spectral type and rate of period change, has not yet been attained.

Overluminosity of the primary, however, cannot account for all the observations. If the secondary is a BO–B2 main sequence star, as sugggested by Kriz, one must assume rapid and probably differential rotation[5]. R. E. Wilson (unpublished) has interpreted the V light curve of β Lyrae using a model in which the secondary is a highly flattened rotating disk. Most of the radiation generated by the star emerges in the direction of the rotational axis, and the polar regions have the highest effective temperature, of some 11,000 to 15,000 K.

Such a temperature is insufficient to excite NV. A Copernicus survey of early-type spectra, communicated to us by D. C. Morton, shows that the NV lines are seen only in stars of type BO.5 and earlier. A model incorporating a hot spot caused by impact of mass exchange particles on the secondary, or its envelope, seems to be eliminated by the lack of strong phase dependence of the line strengths. In addition, the light curve and geometry of the mass exchange raise further objections to a hot spot hypothesis.

The differential rotation model then would require the NV lines to originate outside the orbital plane, and would also require a higher effective temperature than Wilson's model provides. An adjustment in this sense would result from introduction of a hydrogen deficiency in the primary. A similar star, KS Persei, which has a more marked hydrogen deficiency, has an apparent spectral type A5, at variance with the effective temperature 10,000 K (ref. 13). It is not clear whether such an adjustment would make Wilson's secondary hot enough.

Another serious problem is that of the reversal of eclipse depths at wavelengths below about 1,350 Å (ref. 2 and above). Wilson[3] has pointed out that classical models of thermally radiating stars cannot account for this systematic variation. It is not known whether Wilson's differentially rotating model can achieve this.

An alternative representation of the system is one in which the secondary is a black hole. If matter is transferred

Table 3 Observed features

H	Ly α, β broad interstellar absorption.
HeI	Seen only at 2,829 and 2,945 Å.
HeII	Possibly present at 1,085 Å.
CII, III	Present; also primary absorption in V2 region.
NII	Possibly present at 1,085 Å; primary absorption in V2.
NV	Highest excitation found: 1,238 and 1,242 Å.
MgII	Resonance lines at 2,800 Å; P Cyg profiles.
SiII, III, IV	Well represented.
SII, III, IV	Well represented.
FeIII	Well represented; other iron peak elements?

to the vicinity of a black hole at a rate higher than $10^{-9} M_\odot$ yr^{-1}, an accretion disk will be formed of sufficient density to absorb X radiation from infalling material[14,15]. This radiation then appears as a hot continuum, and radiation pressure is high enough to accelerate the excess of matter transferred over mass accreted, away from the system. They also predict the appearance of strong recombination lines of highly ionised elements, with no apparent ionisation source. The high ultraviolet luminosity also ionises the interstellar hydrogen around it, forming an extended Strömgren region. The observations described, the fact that β Lyrae is a thermal radio source[16], and the mass-exchange rate of 10^{-4} to $10^{-5} M_\odot$ yr^{-1}, fit this picture remarkably well.

A complication of a black-hole model, which β Lyrae shares with other binary candidates such as Cygnus X-1, is its evolutionary history[17]. If, as is often supposed, formation of a collapsed object is associated with a supernova explosion, it is necessary to explain the present small separation and circular orbit of the components. Side stepping this point, we may sketch a possible history of the system as follows. The originally more massive star underwent extensive mass loss to its companion after its main sequence lifetime, leaving a He burning core and producing a He rich envelope on its companion. The He core should finish its evolution (as a black hole) long before the 10^6 to 10^7 yr required for the companion (the present primary) to reach the end of its main-sequence lifetime. We now see the second era of rapid mass exchange, in which the He rich layers of the present primary are transferred to an accretion disk around the collapsed companion.

A more extensive examination of the new data is being prepared. We thank the Princeton OAO staff for observing time and assistance. Copernicus is sponsored and operated by NASA.

Behaviour of Comet Kohoutek (1973f)

OBSERVATIONS of Comet Kohoutek have revealed the presence of CH_3CN (ref. 1) and HCN (W. Huebner, private communication) in the coma and of H_2O^+ in the tail[2]; although predicted, H_2O was not observed[3].

The spectral identification of CH_3CN and HCN is the first direct support for the hypothesis first proposed by Wurm[4], of chemically stable 'parent molecules' for the less stable radicals and ions seen in the coma and the tail. Either of these molecules could be the parent molecule of CN, which is conspicuous in almost all comets at $\lambda \approx 3{,}883$ Å. Their radiative dissociation schemes are the following[5,6]:

$$CH_3CN + h\nu \rightarrow CH_3 + CN^*(\lambda \lesssim 2{,}160\ \text{Å}) \quad (1)$$

$$CN^* \rightarrow CN + h\nu(0\text{–}0\ \text{band emission near} \approx 3{,}883\ \text{Å})$$

$$HCN + h\nu \rightarrow H + CN\ (\lambda \lesssim 1{,}900\ \text{Å}) \quad (2)$$

These two molecules were among the earliest discovered in dense interstellar clouds[7]. This does not establish an interstellar origin for comets but seems suggestive of the environment in which comets, or more specifically their embryonic grains, condensed out of the gas phase. These two molecules are also among the most abundant products in the gas phase found in sparkings of simulated primitive planetary atmospheres[8].

The H^2O^+ (most probably formed by photoionisation of H_2O at wavelengths shortwards of about 984 Å; ref. 9); strongly suggests the presence of the latter as another parent molecule. Circumstantial evidence for the presence of H_2O as the dominant volatile component in the nucleus has been growing for some time. The strongest line of evidence has come from the recent ultraviolet and near violet observations of Comets Tago–Sato–Kosaka (1969g), Bennett (1969i), P/Encke, and now Kohoutek (1973f), all of which show strong emission from the two species H(Ly α) and OH($\sim$3,040 Å) (refs 10, 11 and unpublished results from J. E. Blamont and M. Festau). Detailed models of the coma computed on the basis that H and OH are the photodissociation fragments of H_2O seem to explain rather well the observed Ly α brightness distribution[12,13] and the distortion of the isophotes[14]. Under typical cometary conditions with a large abundance of H_2O, other parent molecules would be present in the nucleus as clathrate hydrates, since these are thermodynamically more stable than their constituents[15]. Since the potential wells in which the 'guest molecules' are trapped in the H_2O ice lattice in the clathrate are very deep, they can be released only by the destruction of the 'host' lattice and consequently their vaporisation is controlled by the latent heat of vaporisation of H_2O. This explains the almost simultaneous appearance of all the major cometary emission bands (typically around 3 AU for most comets) although the volatilities of the assumed parent molecules differ by more than ten orders of magnitude, provided that the abundance (by number) of the H_2O molecules exceeds all others by about six to one. This is because the clathrate lattice can typically trap only one 'guest' molecule per six 'host' H_2O molecules. The large abundance of OH ($\gtrsim 90\%$ by number of all the radicals) observed in Comets Bester (1949k) (ref. 16) and Tago-Sato-Kosaka (1970g) (ref. 17) supports this view.

The behaviour of Comet Kohoutek cannot be explained by a pure clathrate nucleus with H_2O exceeding the other molecular species by more than 6 to 1. This is because an extensive dust halo was seen at a distance $R \gtrsim 4$ AU where the vapour pressure of H_2O or the clathrate would have been negligible[18]. A much more volatile species is required. Carbon monoxide, which is one of the most abundant molecules discovered in interstellar space and whose ion CO^+ is probably the most abundant species in cometary tails, is a likely candidate. Formaldehyde, another abundant interstellar species which may be a 'parent' for CO according to the scheme[5] $H_2CO + h\nu \rightarrow H_2 + CO(\lambda \lesssim 3{,}000$ Å), is also a possibility. Methane is a not unlikely alternative. Indeed, the behaviour of Comet Kohoutek can be understood in terms of a nuclear model in which the H_2O exceeds the more volatile species by a factor less than 6:1 so that a fraction of these are not trapped in the clathrate lattice. It is also likely that these more volatile species were concentrated in an outer shell because of a slow outward diffusion. As the comet approached the Sun these volatile species would quickly evaporate around $R \approx 5$ AU, throwing out a dust halo which probably consists chiefly of clathrate hydrate grains, possibly also admixed with grains of the volatile species and more refractory, 'earthy' material. The extension (l) of this dust corona is not determined by the lifetime of the grains against evaporation at 5 AU because this would be too large for any reasonably sized grains (being about 5×10^{10} s for 10-μm grains). Rather it would be determined by their velocity. Taking $l \approx 10^4$ km and $v \approx 0.1$ km s^{-1} gives the time duration of mass ejection as $\approx 10^5$ s (≈ 1 d, which seems reasonable). Assuming that the injection rate of dust is β times that of the gas (Q_{gas}) and that the dust coma is optically thin, the 'effective cross section' of the dust coma for scattering of solar radiation is

$$A_c = \beta Q_{gas} \sigma_g \ \Delta t / m_g = \tfrac{3}{4} \beta \frac{(Q_{gas}\, \Delta t)}{(r_g\, \rho_g)} \quad (3)$$

where Δt is the duration of emission of the volatiles and σ_g, r_g, m_g and ρ_g are respectively the average cross section, radius, mass and density of a grain. Since $Q_{gas} = Z_{gas}\, m_{gas}\, A_n$, where A_n is the nuclear cross section, m_{gas} is the molecular mass of the voltaile and Z_{gas} is the vaporisation rate (molecules cm^{-2}s^{-1}), the ratio α of A_c to A_n is

$$\alpha = \tfrac{4}{3} \beta \frac{(Z_{gas}\, m_{gas})}{(r_g\, \rho_g)} \Delta t \quad (4)$$

Assuming that the volatile in question is CH_4 (which is representative of the highly volatile class and for which reliable data is available[19]), and putting $\Delta t \approx 10^5$s, $\beta \approx 0.1$, $r_g \approx 10$ μm, gives $\alpha \approx 40$. In spite of the overall uncertainty in this value arising from our guessed estimates, this shows that the 'effective cross section' at around 5 AU could have been one or two orders of magnitude larger than the nuclear cross section. Consequently, the earlier estimates of the radius could have been too large by a factor of about three to ten, accounting for the later disappointment.

If the highly volatile material involved is small, this activity will quickly cease and a much less volatile cometary nucleus consisting of clathrate hydrates will be exposed, which will then behave in a 'normal' way after the early 'anomalous' brightening

Comet Kohoutek is by no means unique in its behaviour and five out of a set of about 50 long period comets seem to show anomalous brightenings in 4 AU $\leq R \leq$ 5 AU (ref. 20). A much larger sample (about 75% of a total of 79 comets passing perihelion in a period of 40 yr) exhibited flare activity at smaller heliocentric distances, often repeatedly[21,22], and indeed a significant fraction of all long period comets may be first observed during such flares[23]. These flares, as well as the periodic outbursts from P/Schwassman–Wachmann 1, which moves in a nearly circular orbit with perihelion distance $\approx$ 5.5 AU, can be explained in terms of pockets of the highly volatile material contained within the clathrate lattice, being exposed to solar radiation from time to time as the overlying material evaporates. Other explanations of this phenomenon have been suggested[24,25] but they are less direct.

Any attempt such as this to explain the differences of cometary behaviour in terms of differences in composition runs into the difficulty of having to explain why such differences in composition should exist, and this can only lead to further speculation because next to nothing is known about the spatial regions and therefore the physical and chemical environments in which comets condensed[26]. But we require only very small differences in chemical composition to explain very different behaviour. A comet whose volatile component contains 85% H_2O molecules by number will behave in a 'normal' way, whereas one which has only 84% H_2O molecules by number will flare at a large heliocentric distance ($R \geq 5$ AU) and then fizzle out, like Comet Kohoutek. Such small differences in chemical composition could easily be attributed to random statistical fluctuations. This may also be the difference between genuinely 'new' comets coming into the inner Solar System for the first time and those that have come in at least once before.

Monotonic evolution of Boltzmann's H in weakly coupled gravitational systems

GASES with gravitational interactions are expected to evolve away from a state of uniform density and temperature[1,2]. Such behaviour has been strikingly confirmed by numerical experiments on small gravitational systems[3].

We point out here that this evolution does not contradict the criterion:

$$dH/dt < 0 \qquad (1)$$

Indeed this criterion can even be proved. Here,

$$H = N\int d\mathbf{v}\ \psi(\mathbf{v}) \ln \psi(\mathbf{v}) + \text{constant} \qquad (2)$$

is Boltzmann's H, ψ is the velocity distribution of particles with equal masses m. The weak coupling theory of Prigogine and Severne[4,5] leads to a criterion of evolution of the form defined by equation 1, mainly as a byproduct of the simultaneous increase of random kinetic energy and negative correlational potential energy[6]. The criterion is illustrated in Fig. 1, which, following Miller[3], is a schematic plot of the evolution of the random kinetic energy and Boltzmann's H. They do not approach a limiting value. The approach of the velocity distribution towards a Maxwellian one is deflected by an instability of the Maxwellian distributions themselves.

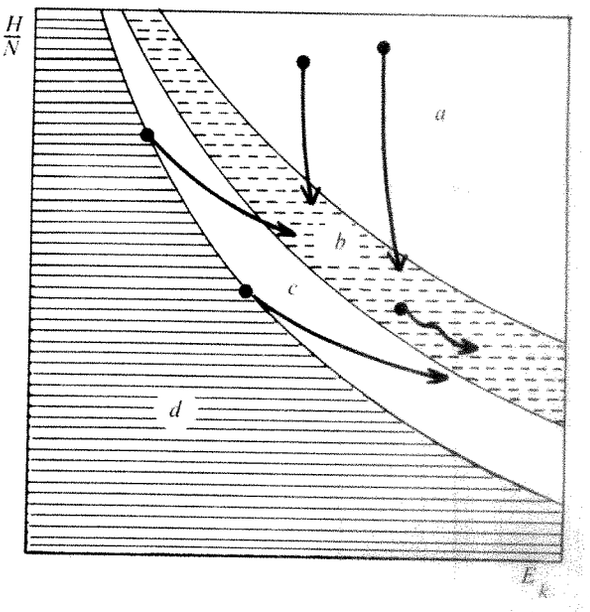

Fig. 1 The monotonic increase in mean kinetic energy per particle, E_k and the monotonic decrease in Boltzmann's H. The size of regions b and c may be much smaller than shown. The line between regions c and d represents Maxwellian velocity distributions ($2E_k dH = -3N dE_k$). Region d contains no allowed distributions. The solid circles represent hypothetical distributions at time t and the arrows show the direction of evolution of H and E_k from these points. Region a is dominated by the usual relaxation of H because of weak binary interactions. Region c is dominated by the kinetic energy production and associated negative potential energy production. The H quantity also decreases there, primarily because of increasing disorder in velocity space as a result of the heating. The evolution in region b is less rigorously established, and the region has not been shown to have boundaries independent of moments of the velocity distribution other than H and E_k. It has, however, been shown that $dE_k/dt > 0$ even in region b, and therefore $dH/dt < 0$ holds everywhere, at least over a period of time.

The Maxwellian is unstable because of distortions associated with the creation of spatial order (ref. 7, and M. J. H., not yet published). This could be crudely described as a dissipative 'flow of entropy' (and of energy) from spatial coordinates to velocity coordinates. Some local order in velocity space develops and is maintained as a byproduct, in spite of the increase in overall dispersion of the velocities.

The spatial order is not reflected in H as it is defined in equation 2, and would have to be taken into account in an appropriate definition of 'total entropy', the evolution of which could be quite different. Work is in progress on the relationship between such a total entropy and the generalised entropy concept being developed by the Brussels school.

We thank Professor I. Prigogine for stimulating discussions. One of us (M.J.H.) was supported in part by the Robert A. Welch Foundation, and in part by NATO.

Sound wave modulation of auroral X rays

A UNIQUELY intense pulsation of auroral-associated X rays, followed a solar cosmic flare in September 1966 and was detected by scintillation counters on a balloon platform at an altitude of about 32 km (ref. 1). The X rays were strongly modulated with a period of 4–6 s. Figures 1 and 2 show a portion of the amplitude-modulated intensity, the ratio of intensities in two neighbouring energy channels, the power spectrum for the X-ray intensity ratio, and the spectrum of intensity variations in the lower energy channel. It can be seen that the X-ray spectrum hardens as the pulsations grow and then softens with the subsequent decay, and that there are two peaks in the X-ray power spectrum.

All these features can be interpreted as an interaction between atmospheric sound waves and a uniform flux of X rays: the intensity modulation results from an atmospheric variable density absorber formed by the sound waves, the energy dependence of the modulation derives from the energy dependence of the X-ray absorption cross section, and the two peaks in the power spectrum are possibly a result of the ducting

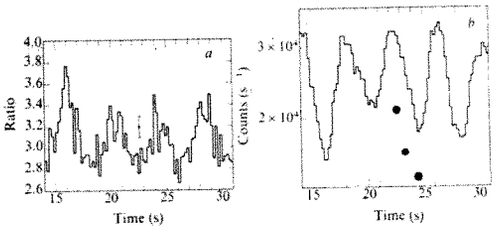

Fig. 1 *a*, Variations in the N(25–50 keV)/N(50–73 keV) ratio and, *b*, N(25–50 keV) intensity for four consecutive peaks in a modulated auroral X ray event, from Brown and Weir[1].

conditions for each of the atmospheric sound channels. First, however, I must digress with a description of the sound ducts.

Infrasonic ducting occurs in the lower and upper atmospheric sound channels, the lower being between altitudes of 5 and 50 km and the upper between 55 and 105 km. Figure 3 shows the lower portion of a sound speed profile based on the COSPAR model atmosphere.

Figure 4 shows the dispersion curves computed by Pfeffer and Zarichney[2] for some of the shorter-period, ducted, acoustic modes. An outstanding feature is the double set of plateaus, a plateau being a region of minimal dispersion—a frequency domain in which wave packets can be formed, propagate and retain identity. At the shorter periods the plateaus alternate between group speeds of 270 and 293 m s^{-1}, the sound speeds in the upper and lower ducts. The mean ratio of periods of neighbouring plateaus, averaged over the third to eighth modes, is about 1.35 (the ratio of the larger central period to the subsequent smaller central period).

The cause of the alternating plateaus, which occur when two partial ducts have a common pressure node at their interface, can be understood from the work of Tolstoy[3]. He shows that approximate eigenvalues for the entire duct can be represented by a lattice of points resulting from the intersections of resonant and antiresonant eigenfunctions for the partial ducts considered separately. The dispersion curve, for the solution of the complete duct, passes through a subset of the lattice points, and as the curve passes from one lattice point to a neighbouring one, most of the energy transfers from one partial duct to the other. If the ducts are excited by an impulsive source, the lattice points acquire the role of coupling frequencies which become the centre frequencies of the principal wave packets.

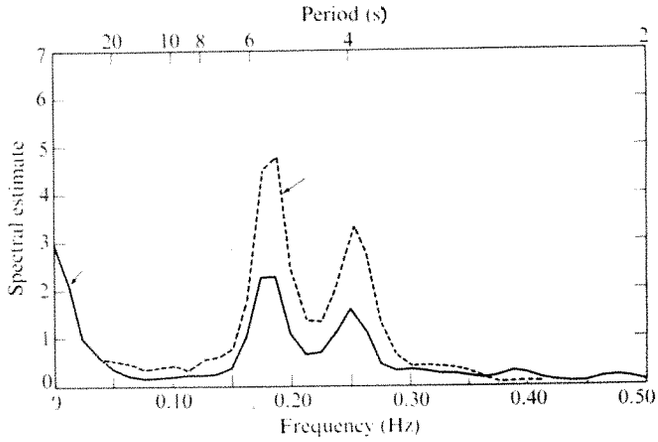

Fig. 2 Power spectra for the X ray intensity ratio N(25–50 keV)/N(50–73 keV). – – –, Intensity variations in the energy range 25–50 keV. (From Brown and Weir[1], 1646.00 to 1649.30 UT.)

In the present case, the lattice points are an ensemble of virtual oscillators with a phase volume so severely restricted that they can be regarded as quantised in period between two levels of group speed (Fig. 4). Such an ensemble, when impulsively excited, will propagate two or more wave packets at group speeds of 270 and 293 m s^{-1}, and the power spectrum of the packets will have two or more peaks. The ratio of the frequencies of sequential peaks, as well as the ratio of the bandwidths of the peaks, is determined by the ratio of the effective widths of the partial ducts which, for the ducts shown in Fig. 3, is 1.35.

Now the ratio of the periods at which maxima occur in the X-ray spectrum is 1.38 and the ratio of the half widths of the two maxima is 22%/16%, or 1.37. These numerical correlations between X ray and ducted sound wave spectra, can be taken as a first suggestion that the X-ray spectrum has a sonic origin. I assume that an upward-looking X-ray telescope, on a balloon platform in the lower duct, will detect modulations

of X rays by sound waves in the lower and upper partial ducts and that the spectra of the modulations will image the sonic spectra.

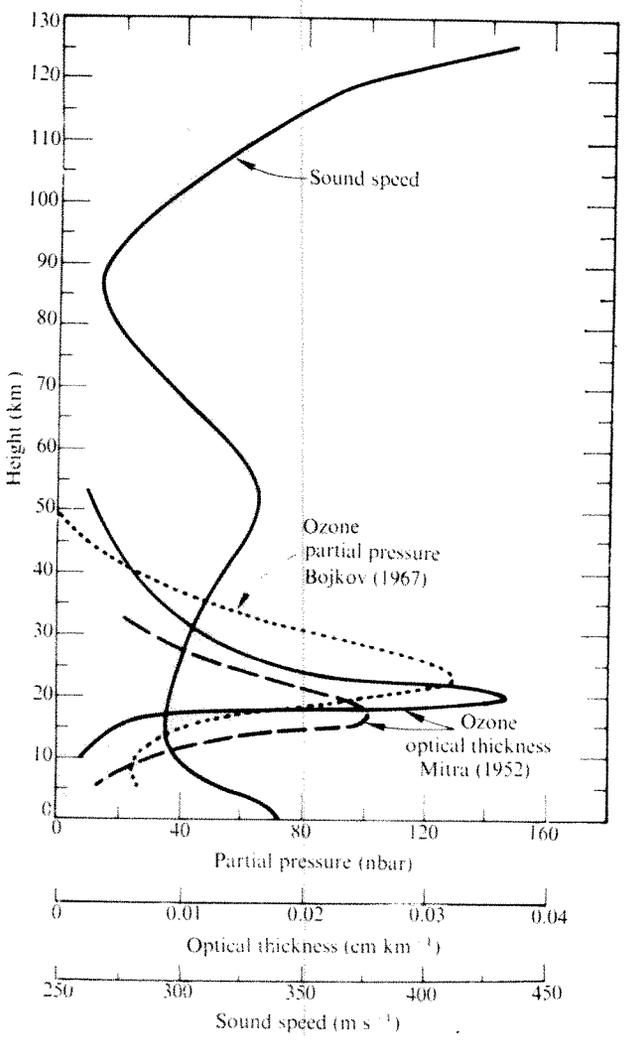

Fig. 3 Sound speed profile based on a COSPAR model atmosphere. Superimposed atmospheric ozone profiles are from Bojkov[10] and Mitra[11].

I shall now consider the magnitude of the sonic condensation required to produce the observed X-ray modulation. Let B_0 be the average X-ray intensity at the height of observation, then the instantaneous value of the intensity, which varies due to change in absorption, will be

$$B = B_0 \exp\left(-\int_{z_0}^{z_1} \xi \mu_1 \rho \, dz\right) \quad (1)$$

where ρ is the ambient atmospheric density, the condensation ξ is $d\rho/\rho$, and μ_1 is the total X-ray absorption cross section in $cm^2\ g^{-1}$. I take $\rho = \rho_0 \exp[-(z-z_0)/H_0]$, assume ξ and μ_1 independent of altitude and integrate equation (1) to obtain

$$\xi = -[\log B/B_0]\,[\mu_1 0_0 H_0)\,(1-\exp-(z_1-z_0)/H_0)]^{-1} \quad (2)$$

where ρ_0 and H_0 are the density and scale height at z_0 the balloon altitude, and z_1 is the height of the top of the lower duct (50 km).

To evaluate equation (2) a weighted mean cross section is the energy interval 25–50 keV must first be computed:

$$\bar{\mu}_1 = \int_{25}^{50} \nu\mu_1 \, dE \Big/ \int_{25}^{50} \nu \, dE \quad (3)$$

where the weighting function, $\nu = \exp[(25-E)/13]$, is based on the e-folding value of 13 keV observed by Brown and Weir. Using the total cross sections in nitrogen given by Siegbahn[4], equation (3) is numerically integrated to obtain $\bar{\mu}_1 = 0.0311$ $cm^2\ g^{-1}$. I determine the ratio $B/B_0 = 1.25$ from the modulations shown in the lower part of Fig. 1, define the rest of the terms in equation (2) for a COSPAR model atmosphere and find that the X ray modulation would be caused by a sound wave condensation $\xi = 0.0835$; however, it is worth correcting this result for the finite angular width of the X-ray telescope, not only to obtain a more accurate condensation but to obtain internal consistency by comparing aperture efficiency with observed percentage modulation.

The aperture width is 26.5° about zenith (R. R. Brown, private communication). I use vertical and horizontal ducted wavelengths of 4.5 and 1.6 km to reconstruct the geometry of the experiment and integrate, graphically, over the solid angle of the aperture to obtain an efficiency of 57%. In making this determination, it is trivial to include a sinusoidal variation in condensation in the integrand in equation (1) because the modulation results principally from oblique alignments of like condensations, much as trees are obliquely aligned in an orchard. I include, however, an obliquity correction for a slight increase in the effective value of scale height. The computed efficiency compares well with the observed modulation, 51%, determined from the observation shown in the lower part of Fig. 1. An efficiency of 57% implies that the condensation required to produce the modulation is 14.6%.

If the ducted disturbance is regarded as the superposition of two obliquely propagating wave trains, then the required condensation in each is a half, or 7.3%. A condensation of this magnitude at 50 km altitude corresponds to 0.21% at ground level, or a pressure disturbance of 27 dyne cm^{-2}. This is surprisingly large but not unusual. Sonic disturbances of comparable magnitude at ground level have been associated with aurora for many years[5].

Can a condensation of 14.6% also produce the energy dependence of the X-ray intensities? The variation of the ratio of the intensities in the intervals 25–50 keV and the 50–73 keV is (d/dp) (N_1/N_2), or

$$d(N_1/N_2) = -(N_1/N_2)\,\xi\rho_0 H_0(\bar{\mu}_1 - \bar{\mu}_2) \quad (4)$$

where $\bar{\mu}_2$ is the weighted mean cross section in the interval 50–73 keV. The negative sign indicates that the fluctuations are out of phase with the density variations, which is confirmed in Fig. 1. Taking the ratio N_1/N_2 to be the average value shown in the top of Fig. 1 and the remaining parameters as used before, I find that a 14.6% condensation will cause a variation in the ratio of X-ray intensities of $d(N_1/N_2) = 0.520$. I have again included a small obliquity correction for effective scale height. This result compares well with the directly observed value of 0.475 (in Fig. 1, half the difference between the maximum and minimum values of N_1/N_2 in the first half cycle).

One additional aspect of the X-ray event can be explained as sound wave modulation. Brown and Weir note that the first part of the event contains the 4-s peak and that the middle of the event the dominant period abruptly changes to 5.5 s. The time difference between the first and second parts of the event is $t = 105$ s. If c_1 and c_2 are the upper and lower duct speeds, then an elementary formula, $r = c_1c_2t/(c_2-c_1)$, that the interval between the two parts of the event can be attributed to the difference in propagation speeds in the two channels from a source at range 362 km.

These sound modulation calculations are also appropriate for that portion of the event which shows modulation characteristic of the upper duct, since modulation that occurs in an elevated layer is invariant to subsequent, lower level absorption. The upper duct, is however, in a more rarified part of the atmosphere and larger condensations would be required to predict the observed modulation. I am inclined to assume that energy in the upper duct extends to or just beyond the interduct boundary, and that greater condensation is not required because modulation occurs at a level near the balloon platform.

When the X-ray observations were made (September 3, 1966, Fairbanks, Alaska, latitude 65° N) the atmosphere was not appreciably different from the reference atmosphere used here. Measurements at 5, 2 and 0.4 mbar, corresponding to heights of about 32, 42 and 55 km, show that differences

between measured and reference temperatures and densities were less than 3 and 1% (ref. 6). Measured wind speeds during this part of the equinoctial period were small, between 10 and 30 knots.

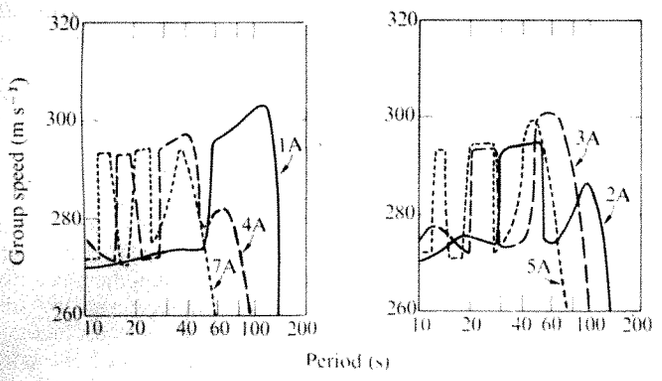

Fig. 4 Machine-computed dispersion curves for ducted sonic modes in a COSPAR model atmosphere, from Pfeffer and Zarichny[2]. 'Plateaus' are the nearly constant speeds at peaks and troughs.

So for a single, especially clear event, it seems that a uniform X-ray flux is density-modulated by ducted atmospheric sound waves. This does not imply, of course, that the X-ray fluxes associated with aurora are always uniform, nor that all X-ray pulsations are the result of modulation by sound waves, ducted or unducted.

There is substantial evidence that ducted sound waves in the upper atmosphere result from volcanic explosions and other natural causes, as well as from nuclear detonations. Baker and Davies[7] report the detection of wave packets generated by nuclear detonations at ranges of about 7,000 km. They conclude that the ionospheric plasma is modulated by ducted sound waves, and the plasma in turn modulates transient radio waves.

If sound waves sometimes modulate X-ray precipitations and ionospheric plasma, other atmospheric phenomena may occasionally be similarly modulated. Little attention has been given to the fluctuations which occur in atmospheric ozone density, possibly because of the use of the Dobson spectrophotometer[8], a device in which short-term variations are averaged. Recently Hering *et al.*[9] studied the fluctuations and concluded that a third to a half of the variance in total ozone content is a result of fluctuations in ozone density at altitudes of 11 to 15 km—the centre of the lower sound duct (Fig. 3).

I recall with pleasure conversations and correspondence with Dr Robert R. Brown.

Five-year climatic trend in the Northern Hemisphere

Results reported by Starr and Oort[1] reflect changes which have occurred in the instruments, in the methods used at the observing stations to interpret radiosonde measurements, and from the setting up of new stations, rather than from real geophysical changes.

Observations of the upper air are mainly made by measuring signals originating from airborne sensors. The measurements are converted into reports in conventional units by complex processes which incorporate corrections designed to reduce errors inherent in the system. For example, in some systems corrections are applied to the temperature measurements for the effects of lag and solar radiation on the temperature sensor, and to the pressure measurements for the effect of temperature on the pressure sensor. Different instrument systems and different conversion and correction techniques are used at different stations. Moreover, changes of instruments and techniques are introduced piecemeal. The practical effect is that, effectively, different absolute standards are brought into use. Thus, although the units are all called by the same name they have some of the properties of 'floating' international currencies in that both their international exchange rates and their apparent relation to materials vary with time. The changes are partly because of gradual improvements in the quality of techniques for observing the upper air, which are taking place at different rates in different parts of the world.

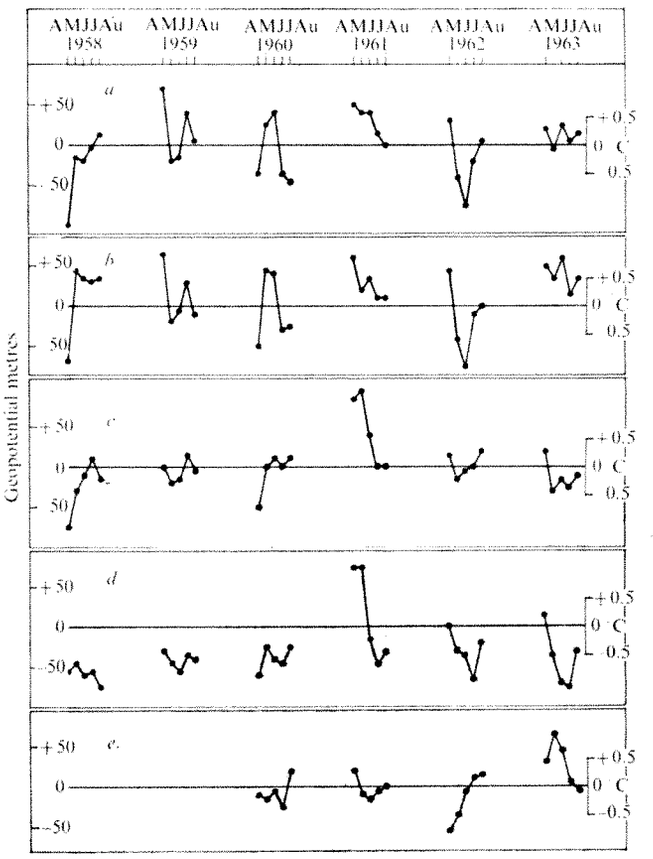

Fig. 1 Deviations of individual values of monthly mean 1,000–100 mbar geopotential thickness from 6-yr averages of the same named month from April to August. *a*, Crawley at 00Z relative to 00Z averages 1958–63; *b*, Crawley at 12Z relative to 00Z averages 1958–63; *c*, Gibraltar at 00Z relative to 00Z averages 1958–63; *d*, Gibraltar at 12Z relative to 00Z averages 1958–63; *e*, Gan at 12Z relative to 12Z averages 1960–65. Equivalent temperature scales for uniform temperature change with height are on the right. A, April; M, May; J J, June July; Au, August.

The most important changes have been aimed at reducing the effects of balloon wake, solar radiation and lag (in a temperature lapse environment), all of which give readings which are high relative to the true air temperature at the level. The net effect of the changes has, therefore, usually been to lower the temperature reported in conventional units relative to that which would have been formerly reported. The introduction of new stations using observing systems different from those of the pre-existing stations can have similar effects on areal analyses. World events such as the IGY 1957 and the IQSY 1964–65 tend to stimulate such changes. Water vapour mixing ratios are calculated from the measurements of pressure, temperature and relative humidity. Consequently, even if relative humidity measurements do not change, apparent changes in air temperature are associated with apparent changes in humidity mixing ratio.

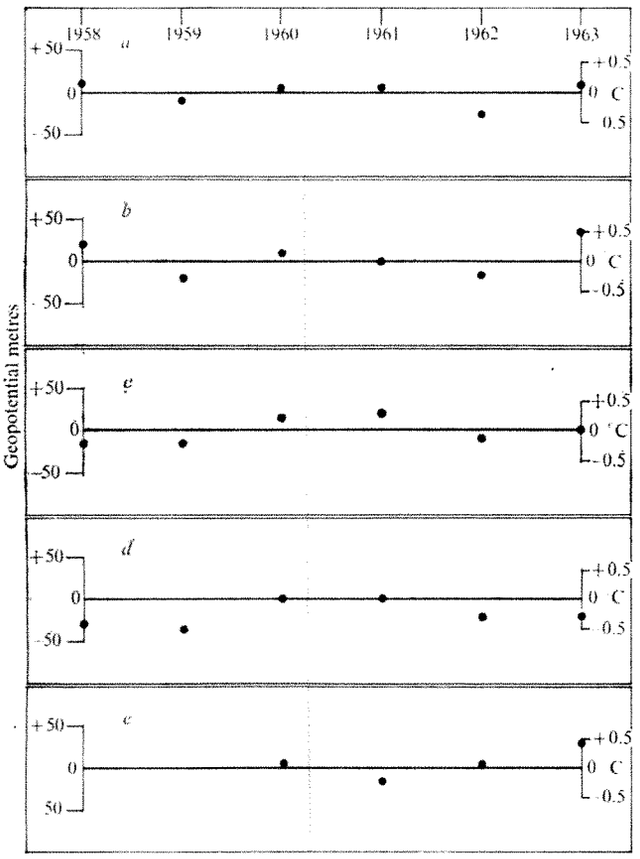

Fig. 2 Twelve-month averages, May to following April, of individual deviations of monthly mean 1,000–100 mbar geopotential thickness from the 6-yr averages of the same named months. Letters as in Fig. 1. Equivalent temperature scales for uniform temperature changes with height are on the right.

Changes such as these invalidate a straightforward geophysical interpretation[1] of the trend in temperature and humidity mixing ratio for the Northern Hemisphere.

Between 1958 and 1963 changes introduced into British radiosonde practice are likely to have had little effect upon the systematic errors of measurements from British controlled stations up to 75 mbar. Examination of quantities such as the monthly mean 1,000–100 mbar geopotential thickness for named months (preferably in summer) at such stations situated where Starr and Oort[1] (Fig. 3 of ref. 1) indicate a material trend in the vertical mean mass-weighted temperature, should serve as a direct check of the validity of a geophysical interpretation of their result. The 1,000–100 mbar geopotential thickness is a sensitive measure of vertical mean height-weighted temperature and a decrease of 1° C in temperature, uniformly distributed in the vertical, is associated with a decrease of 67 geopotential metres (g.p.m.) in the 1,000–100 mbar geopotential thickness. The relationship between vertical mass-weighted mean temperature and 1,000–100 mbar thickness depends upon the distribution of temperature change with altitude. If, however, negative temperature changes tend to increase with altitude (as for the most part indicated by Starr and Oort, Fig. 2) a change of −1° C in the mass-weighted mean temperature would correspond to more than the −67 g.p.m. in 1,000–100 mbar thickness associated with −1° C for a uniform change of temperature with altitude.

A check has been carried out using data for individual months for Crawley (51°N 00°W), Gibraltar (36°N 5°E), and Gan (01°S 73°E). Starr and Oort[1] indicate trends close to −1° C in the vertical mean mass-weighted temperature between 1958 and 1963 at each of these stations. Each of the series showed only minor variations and no trend (Figs 1 and 2). Whether or not the last points in Fig. 2 are considered, the evidence indicates that no persistent trend in the average atmospheric temperature occurred. In both figures the mean values of 1,000–100 mbar thickness at 12Z in Gibraltar are systematically lower than associated values at 00Z. This contrasts with the result from Crawley. (If it is a real result it implies that the atmosphere over Gibraltar is a little colder near noon than near midnight.) It arises from differences on the 12Z soundings at the two stations in the mean albedo underlying the sondes. (At the time this albedo was assumed to be 0.4 for solar radiation correction techniques. When, as often happens at Gibraltar in summer, the albedo actually experienced by the sonde in 12Z soundings was less than 0.4 there was an over-correction for solar radiation effects.) It illustrates one of the ways quantities measured in the upper air and reported in the same nominal units can apparently vary in an unreal manner.

Using Gan as a new station with soundings which yield temperatures systematically lower than those of Indian radiosondes, will probably have the effect of reducing analysed temperatures within its area of influence relative to those indicated before Gan was used.

Similar apparent changes (mainly downwards) in the mean temperature of the upper air and associated changes in mean humidity-mixing ratio can be expected in some regions long after 1963.

C. L. Hawson

Meteorological Office,
London Road,
Bracknell, Berkshire RG12 2SZ, UK

Received January 20, 1974.

[1] Starr, V. P., and Oort, A. H., *Nature*, **242**, 310–313 (1973).

Drs Starr and Oort Reply: Hawson's contention that local changes in instruments and in the method of reducing the data would explain the downward trend in hemispheric mean temperature seems highly improbable. These factors may be important in the case of a few radiosonde stations used in the analyses. In our sample of more than 600 upper air stations, however, the instruments and procedures between different countries vary so widely that the quite systematic changes are more compatible with the interpretation of a real 5-yr trend.

Furthermore, the computed values at our lowest level (1,000 mbar) agree well with those computed from surface records[1]. Neither set of data shows any appreciable 5-yr temperature trend close to the surface. As the independent observations[1] were made with the aid of surface instruments which, presumably, are not affected by the radiation corrections mentioned by Hawson, the agreement suggests

*May, 1958–April 1959, May, 1959–April, 1960 and so on.

that these factors do not play an important role in the upper air data which we used.

Hawson's data points, together with our values for the nearest grid point, are reproduced in Fig. 1. (For practical reasons it was not possible to extract the data at exactly the same location.) The two sets of data are in reasonably good agreement in spite of the smoothing introduced by our objective scheme of data interpolation. The trend at each grid point is evidently small in comparison with the background 'noise' from natural variability. This supports the view that significant results cannot be expected from the study of only a few months of data for a few selected points. Large areas must be considered before possible climatic trends can be delineated.

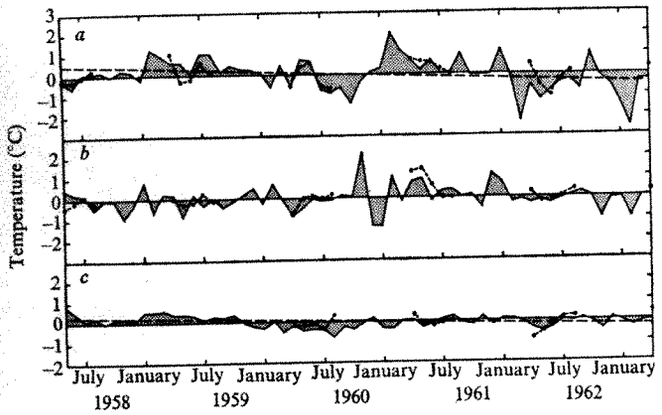

Fig. 1 Temperature deviations (00Z) from the normal annual cycle during the period May 1958–April 1963 for: *a*, Crawley (51.0°N, 0.1°W) trend = 1.0° C every five years; *b*, Gibraltar (36.1°N, 5.2°W) trend = 0.0° C; *c*, Gan (0.4°S, 73.1°E) trend = 0.5° C; short-dashed line-segments, according to Hawson; full line deviations at the nearest grid points in the present analysis (52.7°N, 0.0°W; 33.9°N, 5.2°W and 0.4°S, 73.3°E, respectively); linear trend lines computed from the present data. (Our earlier map showed a trend of about −1° C every 5-yr in Gibraltar. This was because of a minor inaccuracy in the drawing of the isolines.)

Dronia[2] has studied a large set of mean thickness maps of the 1,000 to 500 mbar layer of about 50% of the geographical area in the Northern Hemisphere. This thickness is a measure of the vertical mean temperature in the lower half of the atmosphere. Our results are in excellent agreement with Dronia's results (Table 1) in spite of differences in data reduction and analysis procedures.

Frictional constraints on thrust, wrench and normal faults

IT is generally true that in ancient fault zones, quartzo-feldspathic mylonites which indicate partial plastic yield throughout a volume of rock[1], are most extensively developed in association with thrust faults. They are less widespread along wrench faults (unless the finite displacement is very large) and are comparatively rare along normal faults[2]. The release of seismic energy at shallow depths follows the same general pattern. More than 90% is released in areas of compressive plate interaction, mostly where underthrusting is the dominant mechanism, whereas only 6% is derived from the midocean ridges, where tensional rifting is operative[3].

The analysis presented here, which accounts for these observations at least in part, quantifies a suggestion put forward by Anderson[2]. It is applicable to any existing fault the behaviour of which is approximately governed by the linear frictional failure criterion

$$\tau > \tau_f = \mu\sigma_n$$

where τ is the applied shear stress, τ_f is the frictional shear resistance, μ is the coefficient of static friction, and σ_n is the normal stress across the fault. This will include faults made up of discrete planes and also low cohesion crush zones which can

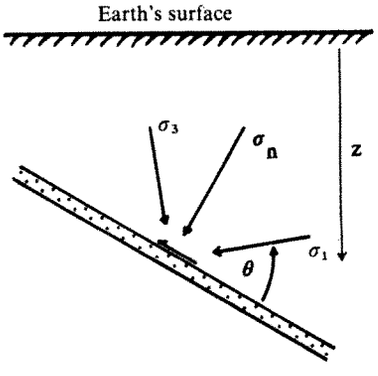

Fig. 1 Stresses around a fault zone at a depth z in the crust.

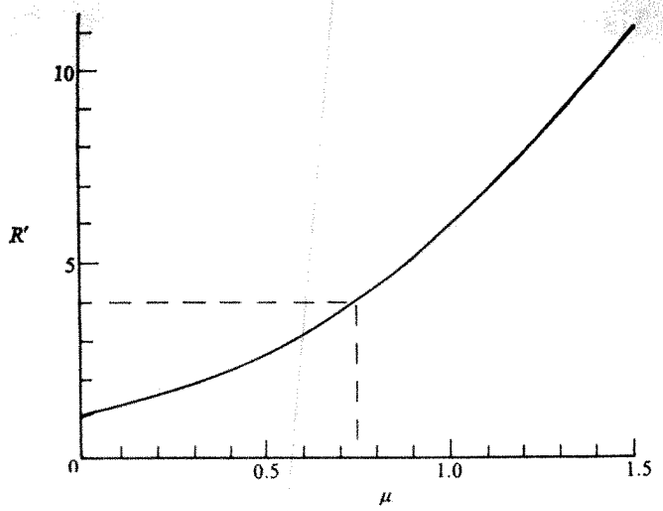

Fig. 2 Minimum ratio of principal stresses (R') required to initiate sliding on a plane with coefficient of static friction, μ.

be treated as granular aggregates of quasi-elastic rock particles[4]. (In fact, the addition of a low-value term for intrinsic cohesion across the fault will not greatly affect the outcome of this argument.) Figure 1 illustrates the stresses acting on a planar fault zone at a depth z in the crust. Throughout this discussion, σ_1 and σ_3, the greatest and least principal compressive stresses respectively, are considered as acting in a plane normal to the

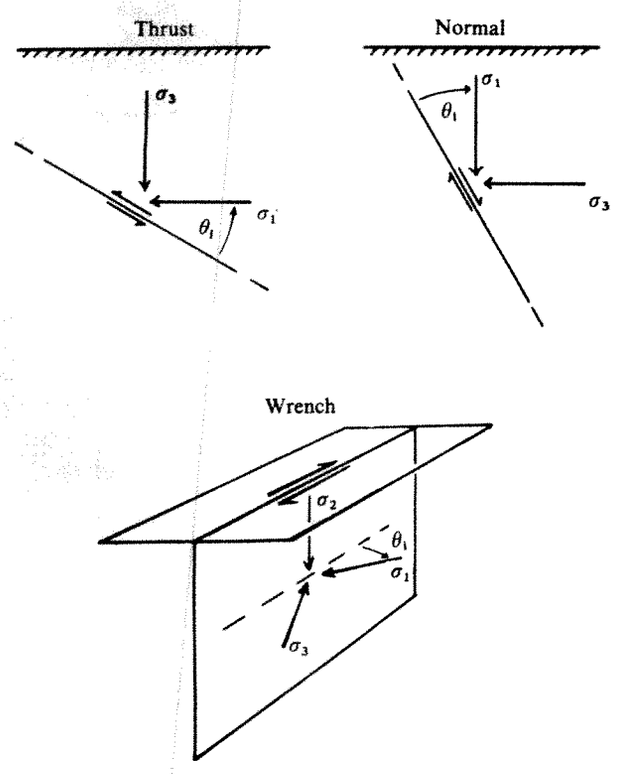

Fig. 3 Anderson's dynamic classification of faults.

fault. The condition for sliding may be rewritten in terms of the the principal stresses as

$$(_1\sigma-\sigma_3)\sin 2\theta = \mu[(\sigma_1+\sigma_3)-(\sigma_1-\sigma_3)\cos 2\theta]$$

and putting $R = \sigma_1/\sigma_3$,

$$R = [\sin 2\theta+\mu(\cos 2\theta+1)]/[\sin 2\theta+\mu(\cos 2\theta-1)]$$

By differentiating this expression and putting $dR/d\theta = 0$, it is found that the minimum value of R required to initiate sliding is given by

$$R' = [-(1+\mu^2)-\mu)]^{-2}$$

(see Fig. 2) and occurs only when σ_1 is at an angle

$$\theta_f = \tfrac{1}{2}\tan^{-1}(1/\mu)$$

to the fault. At all other orientations, the ratio of principal stresses needed to initiate sliding will be greater.

Thus, in general, the limiting condition for frictional sliding is

$$\sigma_1 \geqslant R'\sigma_3$$

or

$$(\sigma_1-\sigma_3) \geqslant (R'-1)\sigma_3$$

Typical crustal rocks will have a static frictional coefficient, μ, of about 0.75 (refs. 4 and 5) and therefore $R' = 4$ and the corresponding value of θ_f is about 27°.

It has been shown[2] that many geological faults fall into three classes termed thrust, wrench and normal faults the orientation of which can be explained dynamically in terms of the Navier–Coulomb failure criterion ($\tau = \tau_0+\mu_i\sigma_n$; where τ_0 is the cohesion and μ_i is the 'internal friction' of the rock mass), assuming that one of the principal stresses is vertical and the other two lie in a horizontal plane (Fig. 3). When the fault first forms, it does so at an angle θ_i to σ_1, where $\theta_i = \frac{1}{2}\tan^{-1}(1/\mu_i)$. In most cases θ_i will not differ greatly from θ_f, the optimum angle for frictional sliding.

The effective overburden pressure at a depth, z, in the crust is given by

$$\sigma_v = \rho g z(1-\lambda)$$

where ρ is the crustal density, g is the acceleration due to gravity, and the pore-fluid factor $\lambda = P/\rho g z$, P being the pore-fluid pressure.

Thus, in a thrust fault regime, where $\sigma_v = \sigma_3$, the limiting inequality for frictional sliding is

$$(\sigma_1-\sigma_3) \geqslant (R'-1)\rho g z(1-\lambda)$$

In a wrench fault regime, $\sigma_v = \sigma_2$, and σ_2 may be written in the form

$$\sigma_2 = \sigma_3+k(\sigma_1-\sigma_3)$$

where $0 < k < 1$. In this case, the limiting inequality for frictional sliding is

$$(\sigma_1-\sigma_3) \geqslant \{(R'-1)/[k(R'-1)+1]\}\,\rho g z(1-\lambda)$$

and if $\sigma_2 = (\sigma_1+\sigma_3)/2$, (that is, $k = \frac{1}{2}$), the inequality becomes

$$(\sigma_1-\sigma_3) \geqslant [2(R'-1)/(R'+1)]\,\rho g z(1-\lambda)$$

In a normal fault regime, where $\sigma_v = \sigma_1$, the limiting inequality for frictional sliding is

$$(\sigma_1-\sigma_3) \geqslant [(R'-1)/R']\,\rho g z(1-\lambda)$$

Thus at a given depth, z, and pore-fluid factor, λ, the ratio of differential stresses required to initiate sliding on thrust, wrench ($k = \frac{1}{2}$) and normal faults is, respectively

$$(R'-1):2(R'-1)/(R'+1):(R'-1)/R';$$

and if $R' = 4$ ($\mu = 0.75$), the ratio is 4:1.6:1 (Fig. 4). (Note that as k varies from 0 to 1, the minimum differential stress required for wrench faulting increases from that required for normal faulting to that needed for thrust faulting.)

The expression for the distortional elastic strain energy per unit volume can be written in the form

$$E_d = [(\sigma_1-\sigma_3)^2/6G]\,(1-k+k^2)$$

where k is as already defined and G is the rigidity modulus. Clearly, if R' is again 4, and for identical λ values, the volume density of distortional strain energy stored at the same depth around thrust, wrench and normal faults respectively (all with $k = \frac{1}{2}$) just before slip, is in the ratio 16: 2.56:1. Stress regimes associated with thrust, wrench and normal faults respectively, are broadly equivalent to those inferred at crustal depths for the different types of plate boundary, arcs, transforms and ridges. Thus, the observed pattern of seismic energy release at shallow depths, and also the fact that the largest magnitude shocks occur in arc regions where underthrusting is operative, are not solely caused by varying areas of contact between lithospheric plates as has been suggested[3], but are to some extent a consequence of the different stress regimes associated with the three types of plate boundary. This conclusion is of course dependent on the assumption that the shallow earthquake mechanism is indeed a process, such as stick-slip, which is controlled by friction.

Assuming that there is some upper limit to differential stress, above which it is easier for rocks to deform plastically by distributed shear throughout a volume, than by frictional sliding on a plane[5], then the critical depth for this transition

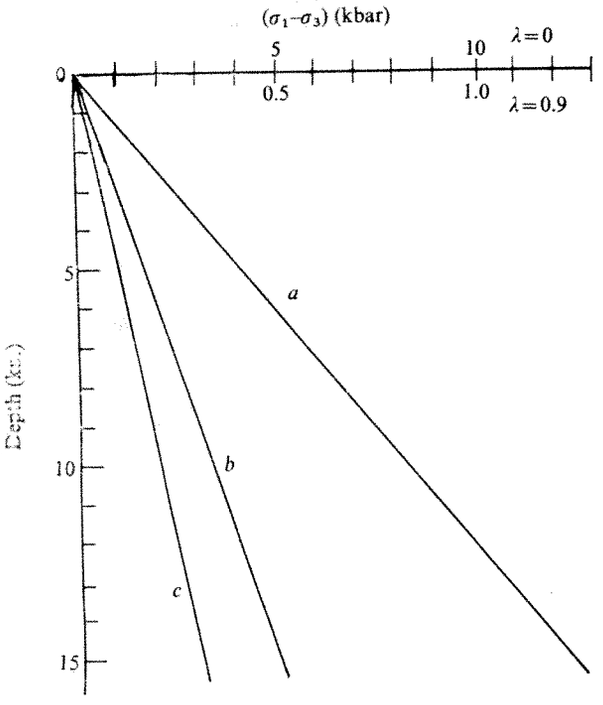

Fig. 4 Minimum differential stress required to start sliding on ideally oriented thrust (*a*), wrench ($k = 0.5$) (*b*), and normal faults (*c*), against depth in the crust. ($\rho = 2.8 \times 10^3$ kg m^{-3}; $g = 9.8$ m s^{-2}; $\mu = 0.75$; $\theta_f = 27°$.)

to plastic yielding will be in the ratio 1 : 2.5 : 4 around thrust, wrench ($k = \frac{1}{2}$) and normal faults respectively, if temperature effects are neglected, $R' = 4$, and λ remains the same throughout. This explains rather well the observed distribution of mylonites in fault zones.

Absolute values for the shear stress within crustal fault zones are thought not to exceed a few hundred bars[6,7]. It is therefore unlikely that the associated differential stress will exceed 1 kbar at the very most. If this is so, it is apparent from Fig. 4 that high pore-fluid pressures are an absolute necessity if faulting (especially thrust faulting) is to take place by frictional stick-slip to a depth of 20 km or more[8]. This condition is most likely to be maintained in the forefront of island arcs where 'wet' sediments are thought to be continually dragged down by the underthrusting process. With large wrench fault zones, it is hard to escape the conclusion that water must be continually injected into the zones from the deep crust or upper mantle, at pressures considerably greater than the hydrostatic head.

I thank Dr N. J. Price for many helpful discussions.

Marscoite and the origin of andesites

THE present communication points out certain discrepancies between the arguments of those who dispute a contamination origin for andesitic lavas and the evidence provided by one specific and well documented example of contamination.

Green and Ringwood[1] have suggested a model for the primary derivation of andesite from mantle rocks, which relies heavily on the fact that andesites have low 'mantle-type' $^{87}Sr/^{86}Sr$ ratios, which cannot be explained by "theories involving melting of sialic material in orogenic zones, or the contamination of mantle-derived basalt magmas with sialic material". Mainly on this basis, they propose a model of mantle derivation.

In a study of Quaternary lavas from the Cascade range, Peterman *et al.*[2] come to a similar conclusion using two main arguments. First, that the low ratios of around 0.7032 for $^{87}Sr/^{86}Sr$ are very similar to those of the accompanying basaltic rocks and "suggest a mantle origin" (see Table 2); second, that "the extremely high Sr contents of the andesites . . . indicate that these rocks could not have been formed by . . . mixing of basaltic magma and greywacke or partial fusion of greywacke." This is seen from Table 2, and in Peterman's Fig. 1, which show that mixing of reasonable ratios of basalt and greywacke to give the major element composition of andesite would result in a rather lower Sr content for the hybrid than is actually seen in andesites.

I believe that both arguments can be answered by evidence provided by Moorbath and Bell[3] in their study of strontium ratios in igneous rocks from Skye. At the classic locality of Marsco, Wager *et al.*[4] have shown that marscoite results from the mixing at depth of a ferrodiorite magma, which they believe to be a differentiate of the Cuillin intrusion, and a porphyritic felsite magma.

Marscoite shows several analogies with the presumed manner of andesite generation by contamination theories. Both chemistry and mineralogy (Table 3) and the K-feldspar, sodic andesine, quartz and hornblende assemblage, indicate that it is an andesitic rock.

Table 1 Geochemistry of Marsco rocks

Rock type	Range of $^{87}Sr/^{86}Sr$	Average $^{87}Sr/^{86}Sr$	Average Rb (p.p.m.)	Average Sr (p.p.m.)
Ferrodiorite	0.7112–0.7133	0.7123	47	256
Marscoite	0.9124–0.7139	0.7129	78	238
Felsite	0.7123 ± 0.0020	0.7213	113	15

The most noticeable difference is that the MgO/(FeO + MgO) ratio is 0.173 in the marscoite and 0.443 in the hornblende andesite, this may be partly because whereas andesite, on the contamination model, is assumed to have a basaltic parent, marscoite has a more differentiated tholeiitic parent, which would be expected to impart a lower Mg/Fe ratio to a hybrid derived from it.

The acid parent of marscoite, porphyritic felsite, has a very high $^{87}Sr/^{86}Sr$ (Table 1) ratio which is typical of rocks derived by partial melting of crustal material (probably Lewisian in this case). The mixing of ferrodiorite and porphyritic felsite magmas is therefore analogous to the presumed contamination model of andesite in which basaltic magma mixes either with crustal material or with liquids produced by partial melting of such material, and as the analyses show, the Marsco case at least produces an andesitic rock. In addition, Carmichael[6] has cited evidence of magmatic mixing in dacites from the Cascade Range, and considers that it is equivalent to contamination.

With reference to Peterman's two main arguments against the contamination origin, two statements from Moorbath and Bell are pertinent (see Table 1).

First, "a mixture of 60 parts ferrodiorite and 40 parts porphyritic felsite" (which is the ratio suggested by Wager *et al.*[4] as necessary to give the observed major element composition of marscoite) "would have an initial $^{87}Sr/^{86}Sr$ ratio of 0.7127, which is still within the limit of error of both the ferrodiorite and marscoite. In spite of the fact that the initial $^{87}Sr/^{86}Sr$ ratio of the porphyritic felsite is considerably higher than that of the ferrodiorite, the ratio of common strontium (porphyritic felsite/ferrodiorite) was presumably too low to affect the initial ratio of the ferrodiorite significantly when the rocks were mixed in the above ratio". Second, "a mixture of 60 parts ferrodiorite and 40 parts felsite would have a Sr content of 60 parts per million (p.p.m.). This is considerably lower than the value observed for marscoite and suggests that marscoite contains an excess of common strontium from some extraneous source."

The implications of these statements can be summarised thus: Marscoite shows clear evidence of being a hybrid of a basic and an acid magma, and has the same isotopic composition, within experimental error, as its basic parent; andesites, petrologically similar to marscoite, have the same isotopic composition as basalt. The hybrid origin of andesite is, therefore, not precluded by this strontium ratio data. The data on Sr concentration for marscoite and its presumed parents are inconsistent, and so these data cannot preclude a hybrid origin for andesite, particularly as the inconsistency is in the same direction for both cases.

Table 2 Geochemistry of Cascade rocks

Rock type	Range of $^{87}Sr/^{86}Sr$	Range Rb (p.p.m.)	Range Sr (p.p.m.)
Olivine basalt	0.7032–0.7039	6.6–22	200–501
Pyroxene andesite	0.7029–0.7030	31–35	1,390–1,490
Hornblende andesite	0.7032	17	1,300
Greywacke	0.705–0.708	Not given	About 200

The present analogy has its weaknesses, such as the great difference in tectonic setting between marscoite and circum-Pacific andesites, and there is not the same paucity of Sr in Peterman's greywackes relative to olivine basalt as there is in the porphyritic felsite relative to the ferrodiorite (Table 2). This is, however, somewhat countered by the simultaneously smaller difference in the $^{87}Sr/^{86}Sr$ ratios of the Cascade basalt and greywacke, so that the increase in Sr ratio produced by contamination is again limited, but from another quarter. A similar 60/40 mixing ratio of basalt and greywacke, each with 200 p.p.m. Sr, would produce a hybrid with a ratio around 0.705, that is, only 0.001–0.002 higher than the basalt.

In order to test this argument further, rather more precise data on the Marsco occurrence are necessary, and it may be that the accurate methods now available will allow the detection of the small (0.01 %) contribution of the porphyritic felsite to the strontium ratio of marscoite.

The 'extraneous source' of strontium would seem to be the main obstacle in the path of further application of this argument. Moorbath and Bell[3] state that the extraneous strontium could not have had a crustal origin, and this reflects favourably on the argument applied to the Cascade results, because it would not then be expected to alter the andesite ratio significantly, assuming that this is the reason for their high strontium contents.

Table 3 Chemical analysis of marscoite and a typical hornblende andesite

	Marscoite[3]	Hornblende andesite[5]
SiO_2	60.07	61.5
Al_2O_3	14.22	14.98
Fe_2O_3	3.71	1.51
FeO	6.65	4.05
MgO	1.39	3.22
CaO	4.35	4.56
Na_2O	4.02	3.59
K_2O	2 75	2.80

Further data on other cocurrences of known hybridisation would add greatly to the understanding of this problem. In the meantime I suggest that the arguments against a contamination origin for andesite through strontium isotopic work are by no means as watertight as many papers seem to imply.

This article was written during a final year degree course at the University of Cambridge, and I thank members of the Department of Mineralogy and Petrology, particularly Dr I. D. Muir, for support and discussion.

Possible thermal explanation of contrasting Archean and Proterozoic geological regimes

THE Earth underwent a remarkable change of behaviour at the Archean–Proterozoic boundary. Greenstone belts intruded by granites dominate the geological record before about 2.5×10^9 yr ago. After that time, essentially no such greenstone belts were formed, and long linear orogens characterised by high-grade metamorphic rocks made their first appearance.

A typical Archean greenstone belt has the following characteristics. Early volcanic activity commonly ranges from ultramafic to mafic, implying high and variable degrees of partial melting of the underlying mantle. Series of volcanic rocks becoming progressively more silicic along calc-alkaline differentiation trends overlie the ultramafic flows. Clastic sedimentary rocks are sporadically interbedded with the volcanic rocks, but predominate towards the top of the pile which can reach a thickness of about 100,000 feet (ref. 1). Diapiric granite plutons cut the greenstone belts which are often preserved only as deep keels between the plutons. Structures within the greenstone belts and granitic rocks indicate that they were deformed by vertically acting forces. The rocks show only low grade metamorphism typically in the greenschist facies, although locally amphibolite and granulite grades are reached. Large areas of platformal sediments are lacking in Archean terrains.

In contrast, the Proterozoic terrains show a clear division into mobile belts and platforms. The mobile belts are long linear features characterised by high grade reworking of pre-existing rocks as well as of newly deposited rocks. Deformation is intense and complex with flow-folding predominating. Transcurrent dislocations characterise many Proterozoic mobile belts. In short, the Proterozoic mobile belts are more similar to Phanerozoic orogens than are the Archean greenstone belts.

The contrasts between the Archean and Proterozoic regimes are commonly attributed to a thin Archean sialic crust[1,2]. But there is evidence to show that the Archean crust may have been as thick as that of the present day[3]. Large areas of continental crust are underlain by rocks 2.5 $\times 10^9$ yr old, or older, yet today many of these areas have sialic crust of normal thickness. Either this was the Archean

thickness or sial has been added to the base of the crust since Archean times. Sial added to the base of the crust would cause isostatic rise of the continent and subsequent erosion, so that the gain in thickness of the crust would be substantially less then the amount of underplated sial. Furthermore, post-Archean isostatic uplift and subsequent erosion would expose rocks with lower K/Ar mica ages, so that Archean ages should not be preserved. We consider it much more likely that the continents have grown by lateral accretion since the Archean, possibly with their thickness being controlled essentially by sea level.

Nevertheless, the differences between Archean and Proterozoic geologic regimes outlined above require an explanation, one which is consistent with the relative sharpness and worldwide nature of the change between the two. We suggest that an explanation lies in the thermal behaviour of the Earth.

There is ample evidence to show that the Earth is cooling[1], presumably because of a decrease in heat production by radioactive decay, and also degassing to form the oceans and atmosphere. The supposedly continuous nature of this cooling has perhaps obscured its potential in causing discontinuous geologic behaviour such as the Archean–Proterozoic transition. But a simple possible explanation lies in the intersection of phase boundaries and the geotherm.

Figure 1 shows schematically the relations between geotherms which, as a result of cooling, would migrate downwards with time, and a hypothetical peridotite solidus which would be progressively higher with lower water pressure, that is, would migrate upwards because of mantle degassing. Partial melting occurs only when the geotherm and solidus intersect, and the degree of partial melting will be proportional chiefly to the excess heat involved. Thus during the Archean, with a high geothermal gradient and high P_{H_2O}, there would be melting over a wide P_{H_2O} interval, with adiabatic rise of numerous mantle diapirs probably in a random geological pattern though perhaps locally controlled by crustal fracture systems. This, along with lower pressure differentiation under high P_{H_2O}, would account for the wide range of both extrusive and intrusive magma compositions, as well as the geological patterns of the Archean greenstone belts.

As the extent of intersection of the geotherm and the solidus is decreased as a result of cooling and mantle degassing, the degree of partial melting should decrease. One might thus expect to see a gradual change in magma compositions (a more restricted range and less hydrous nature) with time in the Archean. But as this process continues there would be a rapid change of behaviour at the point where the geotherm and solidus no longer intersect, such as at point A in Fig. 1. Magma at this point would have a very restricted composition and with further cooling melting would cease. This situation is suitable to explain the nature of the Archean–Proterozoic transition. After this condition obtained there would be no further worldwide magmatism, since it would be restricted to local areas of perturbation of the geotherm or to pockets of high water content. Geothermal perturbations could result from adjustments of the lithosphere (possibly an early form of plate tectonics), thus accounting for the linear patterns of Proterozoic magmatism and tectonics, or possibly in zones of concentrated heat flux (deep mantle plumes) for which there seems to be little Proterozoic evidence. We suggest the former process and further suggest this as an explanation for the relatively constant tholeiitic composition of Proterozoic magmas.

This paper arose from discussion with J. G. Thurlow, S. Swinden, and P. L. Dean.

Pseudo-holography using scattered X rays

A major obstacle to the formation of images with scattered X rays is the lack of a suitable X-ray lens. Radiation at such short wavelengths is not appreciably refracted by matter, which means that a lens, in the optical sense of the word, cannot exist. To overcome this difficulty, a concept can be applied which has previously been used to form an image of sources which emit their own radiation rather than scattering radiation from another source. Basically, the concept consists of a two-step process in which the radiation is used to cast shadows of a coded aperture which are recorded on film. The encoded image is then decoded by one of several possible methods, depending on the type of aperture used. This technique was first proposed for use in X-ray astronomy[1] and has been applied to imaging distribution of γ emitters (refs 2–5, and H. H. Barrett, and F. A. Horrigan, not yet published). We have used a Fresnel zone plate as a coded aperture. This is by no means the only possible aperture, but it does offer some advantages over other types. The advantages involve primarily the ease with which decoding can be accomplished.

The Fresnel zone aperture consists of concentric annular zones of equal area which are alternately transparent and opaque to X rays. Figure 1 illustrates its operation. A

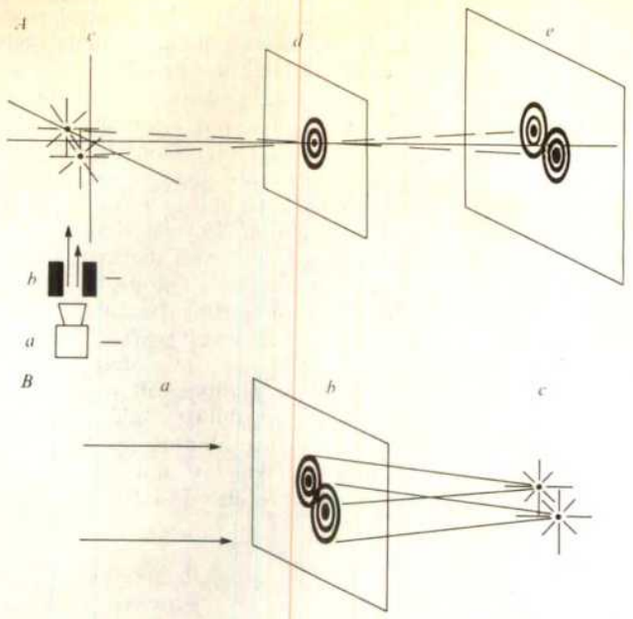

Fig. 1 *A*, Apparatus used to form a shadow of the scatterers: *a*, X-ray generator; *b*, collimator; *c*, scatterers; *d*, Fresnel zone plate; *e*, recording medium. *B*, Formation of an image of the original scatterer: *a*, beam of coherent light; *b*, reduced hologram; *c*, image of point scatterers.

point scatterer is placed at some position on one side of the zone plate. The scattered radiation field casts a shadow of the zone plate on a recording medium such as a sheet of X-ray film. The location of the shadow depends linearly on the position of the scattering point and on the distances between zone plate and film. The shadow, copied at a suitable reduction in size, will be a small Fresnel lens capable of focusing (by diffraction) a beam of coherent light to a point image of the original scatterer (Fig. 1*B*). The focal point of the Fresnel lens is dependent on the size of the shadow and thus on the distance of the scatterer from the aperture. For an actual extended object each point in the object will act as a point scatterer, producing its own Fresnel lens shadow and each lens will reproduce its

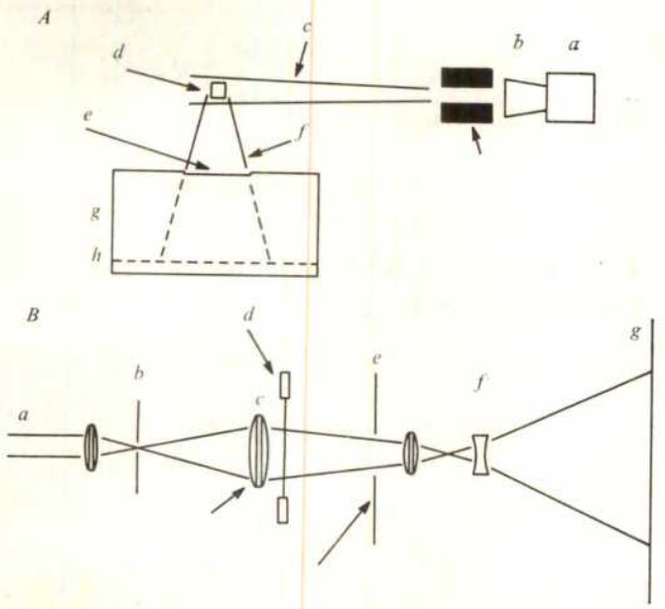

Fig. 2 *A*, Imaging system: *a*, X-ray generator; *b*, collimator; *c*, primary field; *d*, scattering object; *e*, zone plate; *f*, scattered field; *g*, shielding; *h*, X-ray cassette. *B*, Optical reconstruction system: *a*, laser beam; *b*, spatial filter; *c*, transform lens; *d*, hologram; *e*, iris and shutter; *f*, telescope; *g*, image plane.

associated point scatterer independently of all of the others. The superposition of the point images will yield an image of the extended scattering object, and because each plane of the object is at a different distance from the zone plate, it will focus at a different distance from the shadow transparency. As a result, the image will have three-dimensional information which can be viewed tomographically (plane by plane).

The Fresnel zone pattern is familiar as the hologram of a point, and the optical hologram of an extended object can be thought of as the summation of many point holograms (Fresnel zones) formed by each point of the object. This analogy with optical holography implies that the complex shadows of the Fresnel zone aperture can be thought of as a pseudo-hologram of the scattering object, formed by shadowing rather than interference. Decoding can be thought of as the reconstruction of the actual scattered wavefronts.

The imaging system is illustrated in Fig. 2*A*. The primary source was a standard industrial X-ray generator with the beam collimated to a 3-cm circular cross-section and located about 30 cm from the scatterer. For most of the exposures the generator was run at a potential of 90 k*V* and a beam current of 5 mA for an average exposure time of 45 s. The zone plate had 30 zones with a maximum diameter of 10 cm and a minimum width of 0.86 mm. It was used in the on-axis mode and positioned about 8 cm from both the centre of the scatterer and the film in such a way as to view the 90° scattered component. This configuration

Fig. 3 The scattering object.

of the imaging system has theoretical resolution of approximately 2.0 mm as determined by the relative position of the zone plate and the width of the outermost transparent ring.

The opaque rings were composed of a lead powder and glue matrix with an aluminium backing plate comprising the transparent rings. The recording system consisted of an X-ray film cassette with high speed intensifying screens and fast film. The resulting transparencies were copied at a reduction of approximately 64: 1 and placed in the optical reconstruction system (Fig. 2*B*). Light from the helium-neon laser was passed through a spatial filter to clean up the beam and then reconverged through the pseudo-hologram. The real image was initially very small and was therefore magnified and focused on a high speed photographic film packet on which it was recorded.

The scattering object is shown in Fig. 3. The letters were made of aluminium, each approximately 25 mm high, 18 mm wide and 6 mm thick. The aluminium support rod was 2.5 mm in diameter and the letters were positioned with lateral displacement 6 mm and depth separation 12 mm. The purpose of the depth separation was to demonstrate the

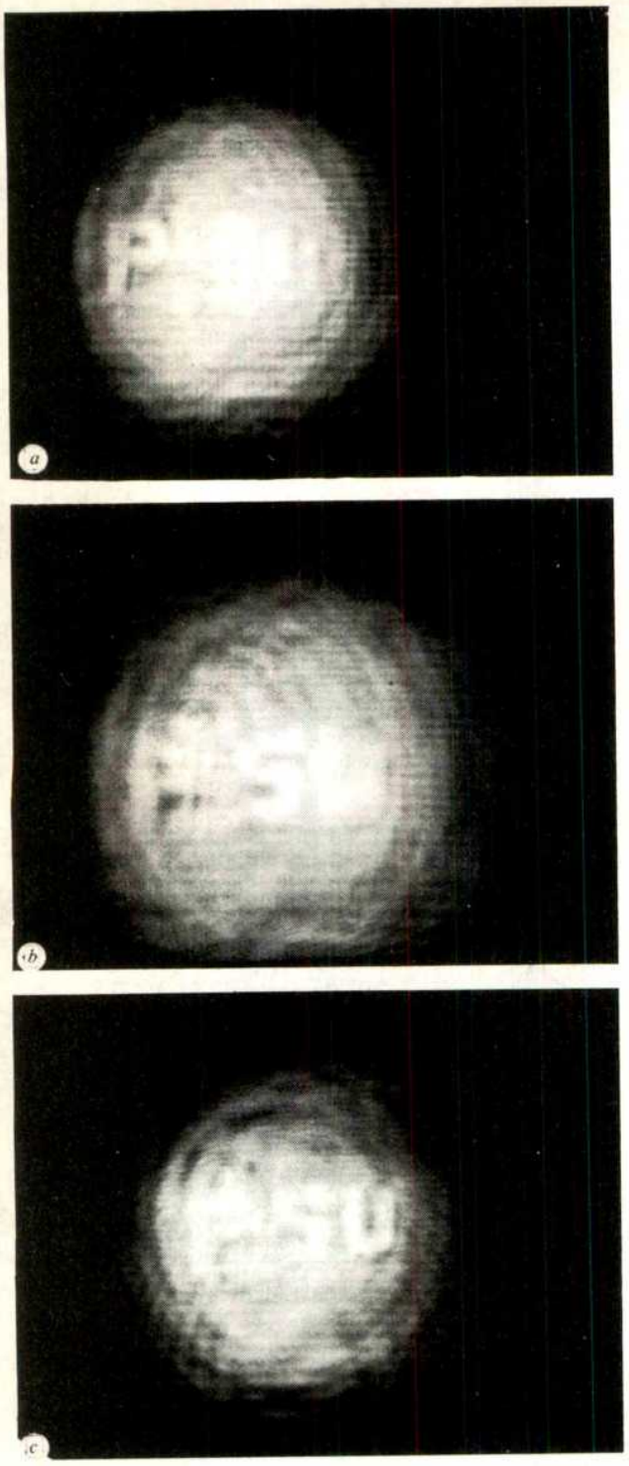

Fig. 4 Reconstructed images of the scattering object (Fig. 3) showing the three-dimensional capabilities of this type of imaging: *a*, focused in the 'P' plane; *b*, focused in the 'S' plane; *c*, focused in the 'U' plane.

three-dimensional capabilities of this method of imaging and its effects can clearly be seen in the reconstruction.

Figures 4*a*, *b*, and *c* show the reconstructed images. The tomographic effect is clearly demonstrated, with each reconstruction corresponding to a different image plane. The theoretical resolution of the system was calculated to be approximately 2.0 mm. This is clearly achieved as the dimensions of the centre of the 'P' are 4 mm by 6 mm. The background appearing in the reconstruction is caused by the undiffracted light passing through the pseudo-holograms. Removal of the background will result in higher quality images and can best be accomplished through the use of the zone plate in the off-axis rather than the on-axis mode. In the off-axis mode the undiffracted component and the image are laterally separated.

The results of this work clearly demonstrate that the use of coded apertures permits imaging with scattered radiation of a very different character from visible light. Although this particular work was done using scattered X rays, it is important that the technique is by no means restricted to that type of radiation. Indeed, similar results have been achieved in our laboratory with thermal neutrons scattering from hydrogeneous material. The use of penetrating radiation is particularly interesting because most of the photons which carry information scatter from the interior of the object. This allows those details of the object which are hidden from photons of visible wavelengths to be viewed. Such a capability could prove very useful in both medical and industrial radiography.

BIOLOGICAL SCIENCES

Tight binding of RNA polymerase to rDNA genes in *E. coli*

THE synthesis of ribosomal RNA (rRNA) in exponentially growing bacteria accounts for approximately half of the total RNA synthesis, although the ribosomal DNA (rDNA) genes make up only 0.3–0.4% of the genome[1]. Electron-microscopic observations[2] and biochemical data[3,4] suggest that the frequency of transcription initiation on these genes is much higher than on any other part of the bacterial chromosome. If the same enzyme is responsible for the transcription of all kinds of bacterial RNA, this difference in the initiation frequency might be due either to a specific regulatory factor or to the structure of the relevant interacting macromolecules themselves. If the latter were true, the DNA promoter sequence responsible for the initiation of transcription on rRNA genes should be more active than other promoters. This hypothesis is supported by the

discovery of preferential *in vitro* rRNA synthesis with purified RNA polymerase in the absence of any external factor[5–7].

Several attempts have been made to characterise the interaction of RNA polymerase with the DNA promoters. Conditions could be found under which RNA polymerase was bound only on distinct sites of the DNA of several simple DNA phages[8,9] and these sites seemed to be the promoters[10]. Fragmentation of DNA did not disturb the specificity of binding[11]. Kinetic analysis of dissociation observed at various ionic strengths revealed that the stabilities of these specific enzyme–DNA complexes were different[8].

The filter binding technique of Jones and Berg[12] as modified by Hinkle and Chamberlin[8] offered the possibility for us to study the interaction of RNA polymerase with fragments of the much more complex bacterial DNA. The easy and extremely sensitive technique of RNA–DNA hybridisation allowed us to differentiate between rDNA and non-rDNA fragments. We reasoned that if the rDNA promoters are indeed more active, then, under certain conditions which favour the dissociation of less stable complexes, that is, at raised ionic strengths, the proportion of rDNA should increase in the bound fraction, provided the fragments are of appropriate size.

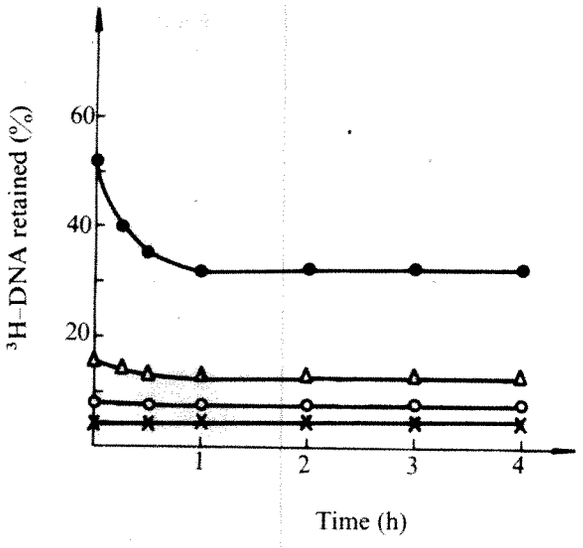

Fig. 1 Highly stable complex of RNA polymerase holoenzyme and bacterial DNA. ^{3}H-labelled DNA from *E. coli* MRE 600 (specific activity 14,200 c.p.m. μg^{-1}) was sheared by passing it several times through an injection needle (No. 16) with syringe to get DNA fragments of average double stranded molecular weight 12×10^6 as determined by gradient centrifugation in neutral sucrose density gradient[17]. ^{32}P-labelled λ phage DNA was applied as molecular weight standard. In order to remove single-stranded ends from the DNA fragments 50 μg sheared DNA was incubated for 5 min at 37° C in 200 μl of reaction mixture containing 0.015 M sodium acetate *p*H 4.6, 0.05 M NaCl, 1 mM $ZnSO_4$, 5% glycerol and 5 μg nuclease S_1 prepared from *Aspergillus oryzae* crude alpha-amylase[18]. The reaction was stopped by the addition of 10 μl M Tris HCl *p*H 8.4, to bring the *p*H to 7.0. RNA polymerase holoenzyme was prepared from *E. coli* MRE 600 according to Burgess[19] as modified by Nüsslein *et al.*[20]. The enzyme synthesised 8–10% rRNA on total *E. coli* DNA template. 4.5 μg nuclease S_1-treated ^{3}H-DNA was pre-incubated for 15 min at 37° C in 0.8 ml binding buffer[8]. Binding reaction was started by the addition of RNA polymerase. After an additional 20 min incubation, 45 μg unlabelled T_7 phage DNA was added to dilute out the dissociated enzyme molecules. During subsequent incubation 100 μl aliquots were removed at the times indicated, diluted with binding buffer to 1 ml, filtered immediately through Millipore HAMP 02500 (0.45 μm) filters under 2 cm of mercury vacuum, washed with 3 ml of binding buffer, dried and counted in a toluene base scintillation fluid. A blank (0.2–0.3%) representing the amount of ^{3}H-labelled DNA retained by the filter in the absence of RNA polymerase were subtracted from all points. The amounts of RNA polymerase holoenzyme added were 1 μg ●; 0.35 △; 0.15 μg ○; 0.1 μg ×.

When ^{3}H-labelled *Escherichia coli* DNA was mixed with highly purified RNA polymerase holoenzyme in a proportion of 4.5:1 by weight, approximately 50% of the DNA was retained on the nitrocellulose filters as DNA-protein complex. On dilution with unlabelled homologous or heterologous T_7 phage DNA the filter-bound radioactivity rapidly dropped to 30% but the dissociation did not go further (Fig. 1). The non-dissociated complex corresponds to the highly stable complex defined by Hinkle and Chamberlin[8]. At a lower polymerase: DNA ratio practically all the enzyme molecules could be found in such a highly stable complex. The proportion of rDNA in this highly stable complex was approximately the same as in the total DNA. If, however, the ionic strength of the medium was increased, the complex progressively dissociated (Fig. 2) and the amount of DNA retained on the filters decreased. The rDNA content of the filter-bound DNA was inversely proportional to the total amount of DNA bound (Table 1). In order to prove that in DNA–RNA polymerase complexes observed at different ionic strengths the enzyme was bound to specific regions of DNA (that is, to promoters) dissociation experiments were repeated in the presence of heparin which inactivates free and non promoter-bound RNA polymerase[13,14]. Heparin destroyed a fraction of enzyme–DNA complexes and the rDNA enrichment in the heparin and salt-resistant complexes was more pronounced (Table 1). Our results do not prove that the observed stability is an exclusive property of rDNA promoters. But in view of the magnitude of rDNA enrichment and the average size of fragments it is obvious that these promoters belong

Table 1 Tight binding of RNA polymerase to rDNA

Salt-resistant fraction M $(NH_4)_2SO_4$	Without heparin		With heparin	
	^{3}H-DNA retained (c.p.m.)	rDNA content (%)	^{3}H-DNA retained (c.p.m.)	rDNA content (%)
0.0 (control)	7,030	0.33	4,940	0.41
0.125	3,630	0.79	2,630	1.20
0.250	1,350	1.87	1,030	2.41
0.375	590	4.26	490	4.95
0.500	370	8.45	310	10.60

14 μg ^{3}H-DNA (average double-stranded molecular weight 12×10^6) treated with nuclease S_1 as described in Fig. 1 was preincubated in 0.8 ml binding buffer for 15 min at 37° C. Binding reaction was started with the addition of 0.6 μg RNA polymerase holoenzyme. After 20 min binding buffer or heparin (1 mg ml^{-1}) was added and 10 min later dissociation was initiated with ammonium sulphate. To measure the amount of salt-resistant enzyme-DNA complex 100 μl aliquots were diluted after 60 min incubation with binding buffer to 1 ml and filtered. For the estimation of rDNA content the rest of the reaction mixture was diluted with 3 ml of binding buffer and filtered. Approximately 95–97% of this filter-bound DNA can be recovered by incubating the filters for 3 h at 37° C in 2 ml of 0.15 M NaCl, 0.015 M Na citrate, *p*H 7.0 containing 200 μg ml^{-1} self-digested pronase. The rest of the bound DNA was liberated by soaking the filters in 1 ml of 0.3% sodium dodecylsulphate at 100° C for 20 min. The pronase and SDS fractions were pooled, exhaustively dialysed against 0.01 M NaCl, 0.01 M Tris HCl, *p*H 7.0 DNA was denatured by alkali and hybridised with ^{32}P-labelled rRNA, specific activity $1.25.10^6$ c.p.m. μg^{-1} on Millipore filters[21]. ^{32}P-labelled rRNA was prepared from *E. coli* MRE 600 growing on 121 pepton medium[22] containing 12.5 mCi KH_2 $^{32}PO_4$ per 100 ml of culture. Before collecting the cells a 200-fold excess of potassium phosphate was added for a generation to chase radioactivity from the messenger RNA. Ribosomes were prepared and purified[23]. rRNA was prepared by phenol extraction and ethanol precipitation and further purified on methylated albumin-Kieselguhr column with a linear NaCl gradient. The hybridisation blank of rRNA prepared in this way was less than 0.02% of input radioactivity.

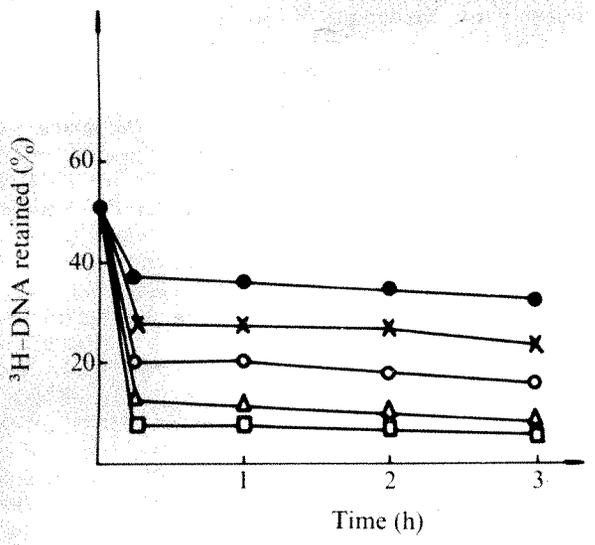

Fig. 2 Effect of ionic strength on dissociation of the highly stable complex. 1 μg RNA polymerase and 4.5 μg ^{3}H-DNA treated with nuclease S_1 was mixed to prepare the enzyme-DNA complex as described in Fig. 1. The complex was dissociated by adding increasing concentrations of ammonium sulphate in the presence of 45 μg unlabelled T_7 phage DNA. At the times indicated 100 μl aliquots were removed, diluted with binding buffer to 1 ml and filtered. The final concentrations of ammonium sulphate were 0.05 M ●; 0.10 M ×; 0.15 M ○; 0.20 M △; 0.25 M □.

to a small group of promoters, representing only a fraction of the total, which might be characterised by extremely tight binding.

As expected, the rDNA enrichment in the salt-resistant complex was smaller if the DNA fragments were larger (Table 2). Under a molecular weight of about 10^6 however, the enrichment effect could not be enhanced, small fragments bound very poorly and the effect was not reproducible.

Elution of the tightly bound complex from the filters was very difficult. One hundred per cent recovery could be achieved only after prolonged pronase digestion plus hot SDS treatment. If the pronase treatment was shorter, only 95% of the bound DNA could be eluted and this fraction was not enriched with rDNA; the bulk of the rDNA was found in the partly pronase-resistant 5% (Table 3). It is known that RNA polymerase becomes more resistant to proteolytic enzymes after binding to DNA, and this is thought to be due to a conformational change[15,16]. Our result suggests that the strong binding of the polymerase at the rDNA promoters might effect this conformational change, rendering the complex even less susceptible to pronase attack.

The demonstration of an extremely strong binding of RNA polymerase to DNA fragments carrying the rDNA genes strongly supports the notion that DNA structure itself might be responsible for the high frequency of transcription on these genes observed both *in vivo* and *in vitro*, although it does not exclude additional regulatory factors.

Table 2 Effect of template molecular weight on rDNA enrichment

Salt-resistant fractions M $(NH_4)_2SO_4$	rDNA content (%) Molecular weight of DNA 34×10^6	20×10^6	12×10^6
0.0 (control)	0.27	0.34	0.32
0.125	0.39	0.50	0.68
0.250	0.61	0.93	1.40
0.375	0.87	1.86	3.43
0.500	1.05	2.15	8.37

Salt-resistant fractions of the RNA polymerase holoenzyme–DNA complex were prepared as described in Fig. 1 applying DNA of different molecular weights. The rDNA content of these fractions was determined by hybridisation with ^{32}P-labelled rRNA.

Table 3 Distribution of rDNA sequences between pronase sensitive and pronase resistant fractions of enzyme-DNA complex

	rDNA content (%)
Pronase-sensitive fraction	0.19
Pronase-resistant fraction	3.1
Total DNA (control)	0.3

A highly stable complex of RNA polymerase holoenzyme and DNA was prepared as described in Fig. 1. The whole reaction mixture without addition of ammonium sulphate was diluted with 3 ml of binding buffer and filtered. Ninety-two per cent of the filter-bound DNA was recovered after incubation for 60 min at 37° C in 0.15 M NaCl, 0.015 M Na citrate, *p*H 7.0, containing 200 μg ml^{-1} self-digested pronase. The rest of the filter-bound DNA, the pronase-resistant fraction, was liberated by an additional pronase digestion for 2 h and hot SDS treatment. Both pronase-resistant and pronase-sensitive fractions were hybridised with ^{32}P-labelled rRNA.

Probable linkage of LCAT locus in man to the α haptoglobin locus on chromosome 16

LECITHIN: cholesterol acyltransferase (LCAT) catalyses the esterification of cholesterol in plasma. Familial LCAT deficiency was first described in 1967 (ref. 1); in 1970 a second[2] family and in 1973 a third, with the same disease, were found in Norway. Seven patients with ages of 26–60 yr

are now known in that country[3].

Clinically the disease is characterised by proteinuria, corneal opacities and normochromic anaemia with decreased erythrocyte life span. The plasma cholesteryl ester and lysolecithin concentrations are decreased, and free cholesterol and lecithin usually increased. Studies of the LCAT-deficient patients have increased our knowledge of normal lipoprotein metabolism in man[4–7]. The fact that the patients develop atherosclerotic lesions when young, even though they have extremely low levels of plasma cholesteryl esters, may help our understanding of the development of atherosclerotic lesions.

The first three families with this disorder have been traced back five to eight generations and most members have come from the same area[8,9]. No inbreeding occurred between the maternal and paternal branches of the families. Moreover, no direct connections have been found between the families. The familial occurrence, the horizontal distribution within families and the fact that the disease manifests itself in both sexes make an autosomal, recessive inheritance pattern likely. The presumed heterozygous carriers (parents and children of the patients) are clinically and biochemically normal. One possibility is that the genetic basis of this disease is the presence of an LCAT-deficiency gene in double dose. This defective gene, operating in all three Norwegian families, is probably the result of one mutational event which occurred at least 250–300 yr ago.

In an attempt to characterise further the genetic defect operating in LCAT deficiency we carried out linkage studies to genetic marker systems currently in common use. The following markers were examined in the three families: A_1A_2BO, Rh (CDEce) MNS, Kell, Fy(b), haptoglobin (Hp), group specific component (Gc), transferrin (Tf) third component of complement (C3), phosphoglucomutase (PGM_1), erythrocyte acid phosphatase (EAP), alanine aminotransferase (GPT) and HL-A.

The studies excluded close linkage between the LCAT gene and the genes determining the marker systems Rh, Duffy, Gc, C3, PGM_1, EAP and HL-A. With respect to the other markers, these families were not sufficiently informative with one exception: nonrandom assortment was observed between LCAT deficiency and Hp types (Fig. 1). The appearance and inheritance pattern of the Hp phenotypes were quite regular in all family members studied, including 15 more distant relatives. When tests for linkage were carried out using a computer program (MOSM) described by Gedde-Dahl *et al.*[10], a combined lod score of 2.81 at a recombination fraction of 0.00 was found. At a recombination fraction of 0.05 the lod score is 2.48. This is very close to a lod score of 3.00 which is usually regarded as good evidence for chromosomal linkage. Given close linkage no recombinants can be counted between the α haptoglobin locus and the LCAT locus.

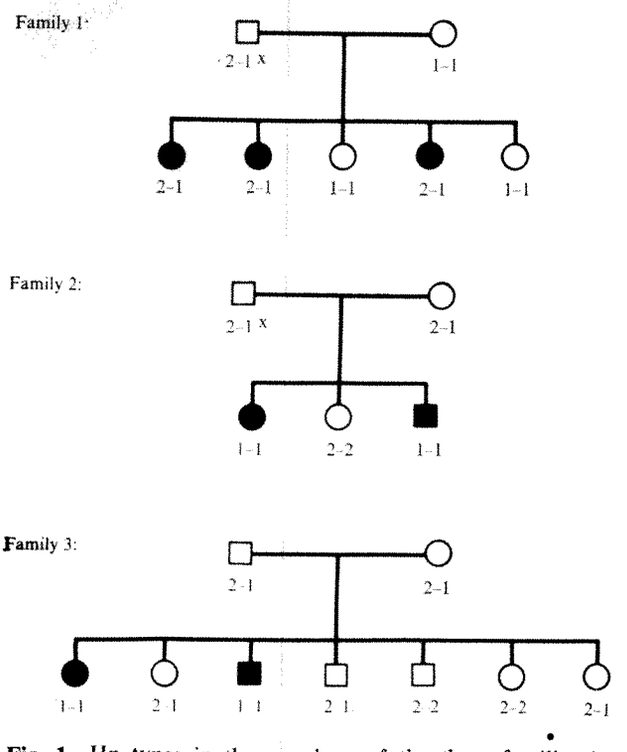

Fig. 1 Hp types in the members of the three families in which LCAT deficiency has been found. ×, Hp types deduced from the types of the other family members; ● ○, females; ■ □, males. ■, ●, Patients with LCAT deficiency; □, ○, family members with no signs of disease.

The total posterior probability of linkage calculated according to Smith[11] was 0.81. A linkage disequilibrium exists, with five out of the six parents handing over the LCAT deficiency gene to their children together with the Hp 1 type. The probability of such a constellation appearing by chance is less than 0.04. Through the period of at least six to eight generations that this gene has existed, only one proven crossover event has taken place. This speaks in favour of close linkage, with a probable recombination fraction of less than 0.05 between the two loci.

Robson *et al.*[12] have shown that the α haptoglobin locus, which determines the genetic variability of haptoglobin, is situated between the middle and terminal point of the long arm of chromosome 16. No case of linkage to this locus has been reported so far.

Our work indicates rather strongly that the LCAT locus is situated on chromosome 16, close to the α haptoglobin locus. This is of interest to geneticists as a new linkage group is added to the human chromosome map. Prenatal diagnostic are not possible at present because haptoglobin is not formed in significant quantities in the foetus.

Our results suggest that the basis of this disease, which reveals an inborn error of lipid metabolism, is a single genetic defect causing a lack of LCAT activity in plasma.

Photoreactivation of sister chromatid exchanges induced by ultraviolet irradiation

In contrast to the inefficiency of ionising radiations in the induction of sister chromatid exchanges (SCEs)[1,2], ultraviolet light can cause a striking increase in the SCE frequency in mammalian chromosomes[3,4]. It has been shown in Chinese hamster cells that the SCE formation requires postirradiation DNA synthesis, and that a single ultraviolet irradiation can induce SCE repeatedly for several cell cycles[4]. As pyrimidine dimers are the major DNA lesions caused by ultraviolet light and as Chinese hamster cells have a poor ability to excise them[5], the delayed formation of SCE seems to be due to unexcised pyrimidine dimers. This possibility was tested here with the use of a rat kangaroo cell line possessing a photoreactivating enzyme[6-8] to see if the frequency of ultraviolet-induced SCE was actually reduced when cells were post-treated with visible light.

The female rat kangaroo cell line, Pt-kl, had a doubling time of about 38 h in our culture conditions[4]. In the first experiment, exponentially growing cells were labelled with ^{3}H-thymidine (0.2 μCi ml^{-1}, specific activity 12.1 Ci mmol^{-1}) for 8 h, washed twice with fresh medium containing 10 μM cold thymidine, drained, and then exposed to ultraviolet light at doses ranging from 20–80 erg mm^{-2} at an incident dose rate of 5 erg mm^{-2} s^{-1}. The cultures were then incubated in normal medium containing cold thymidine. One set of duplicate cultures was kept in the dark, while the other was illuminated for 12 h with visible light from a 20-W fluorescent 'blue light' bulb (National) located 10 cm above the culture dishes. After exposure to visible light, the cultures were returned to the dark. The cells were collected 68 h after ultraviolet irradiation. Colcemid (0.05 μg ml^{-1}) was added to culture medium 8 h before collection, chromosome preparations being made according to the conventional air-drying method. At cultivation, most labelled cells were in the second postlabelling mitosis. Slides were coated with emulsion (Sakura, NR-M2) and, after appropriate exposure times, were developed and stained with Giemsa. The frequency of SCE in the largest (No. 1) chromosomes is plotted against ultraviolet dose in Fig. 1. Ultraviolet irradiation at 80 erg mm^{-2} caused about a four-fold increase in the SCE frequency above a control level, whereas illumination of ultraviolet irradiated cells with visible light lowered the SCE frequency markedly. Thus, at 80 erg mm^{-2} of ultraviolet light, it was only twice the control level. The only ultraviolet-induced DNA lesion that is known to be reversible by photoreactivation is pyrimidine dimer[9]. Now that most SCEs induced by ultraviolet light are photoreactivable, it may be safely concluded that the lesions leading to the formation of SCEs are pyrimidine dimers.

This conclusion was confirmed by experiments in which ultraviolet irradiated cells were kept in the dark for various times before being submitted to photoreactivation treatment and ^{3}H-labelling. The results are shown in Fig. 2. When cultures were kept in the dark, the SCE frequency decreased gradually with time, but it was significantly higher than the control level even 164 h after irradiation. By that time the cells might have undergone division at least three or four times, as mitotic delay caused by the ultraviolet dose used was found to be less than 24 h during this culture period.

These results indicate that a substantial number of pyrimidine dimers remains unexcised, even though the rat kangaroo cells are reported to carry out repair replication after ultraviolet exposure[7], and that the cells might have a repair mechanism that renders them tolerant to the presence of unexcised pyrimidine dimers. These dimers, if not repaired by photoreactivation, would repeatedly provoke SCE before they are either removed by the excision mechanism and/or diluted through consecutive cell divisions. Previous work has shown that induction of SCE by ultraviolet light requires a postirradiation replication and is inhibited by caffeine post-treatment[4]. The involvement of pyrimidine dimers in this phenomenon was confirmed in our study. These features seem to indicate that SCE is closely related to postreplication repair of ultraviolet-induced DNA damage[10-13].

The exact mechanism underlying the induction of SCEs is still unknown. At least, it is probable that the formation of SCEs involves double-strand exchange: assuming that each chromatid contains a single DNA duplex[14,15], only a parental strand in one of the sister chromatids is assumed to contain ^{3}H. A switch of silver grains on an autoradiogram might therefore be an outcome of exchange between the labelled parental strand in one chromatid and an unlabelled daughter strand in another. To achieve this step while avoiding an unwinding difficulty, simultaneous exchange between the remaining two strands of the same polarity in the two sister chromatids would be required. Considering this aspect, Whitehouse's model[16], which was originally proposed to explain genetic crossing over, also seems to be a feasible explanation for formation of SCEs. According to his model, the initial step of crossing-over is the formation of staggered breaks of two nascent, complementary strands from two DNA molecules, which is then followed by a limited replication of the broken ends along the parental template strands. In the induction of SCEs by ultraviolet

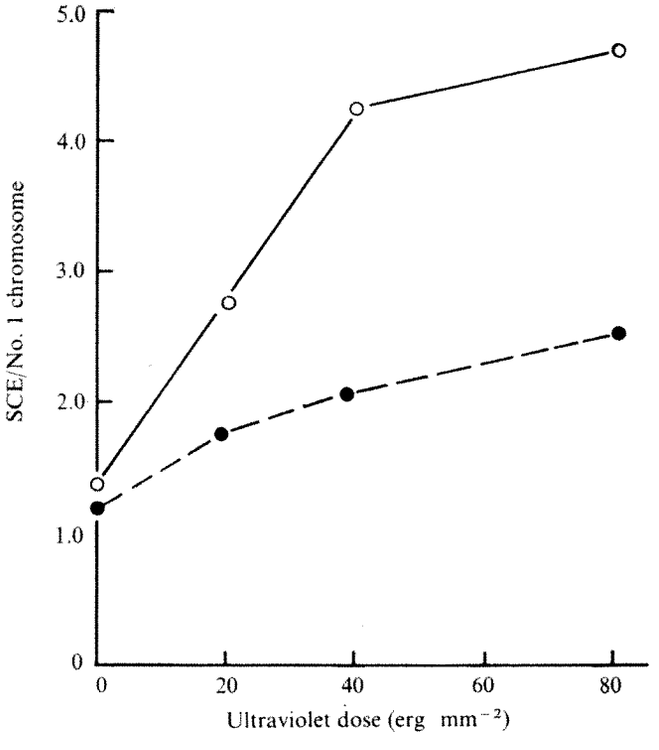

Fig. 1 Dose response curves of (SCEs) with or without photoreactivation treatment. SCE was scored only in No. 1 chromosomes in cells at a diploid level which constituted about 60% of the cell population. Any unlabelled region following a labelled segment of a chromatid and matched by the opposite pattern in its sister chromatid was scored as one exchange. The presence of an unlabelled region within a labelled segment together with the presence of at least three grains on the sister chromatid opposite the region was regarded as evidence that two exchanges had occurred. In ultraviolet irradiated cultures, a considerable number of cells had aberrant chromosomes, so that only intact chromosomes were selected for scoring. No account was taken of whether other chromosomes within the cell were aberrant or not. Isolabellings were omitted from the score. O, Ultraviolet only; ●, ultraviolet and visible light.

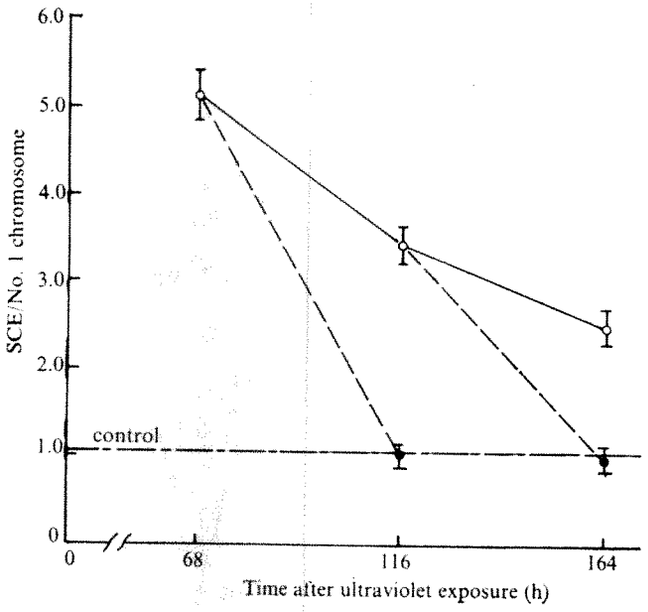

Fig. 2 Delayed formation of SCEs after a single ultraviolet exposure at a dose of 60 erg mm^{-2}. The exchange frequency was determined for only No. 1 chromosomes in the second postlabelling metaphase cells. One set of cultures was labelled with ^{3}H-thymidine for 8 h and exposed to ultraviolet light at 60 erg mm^{-2}. It was incubated in the dark and fixed for chromosome preparation at 68 h after irradiation. Other sets of cultures were first exposed to ultraviolet light at 60 erg mm^{-2} and incubated in the dark for times before being submitted to photoreactivation treatment and ^{3}H labelling: one of duplicate cultures was for 12 h illuminated with visible light from 28 h to 40 h after ultraviolet irradiation, while the other was kept in the dark. Both were then labelled in the dark for 8 h, incubated further and fixed 68 h later, that is, 116 h after ultraviolet irradiation. A similar procedure was applied to the remaining set of cultures: one of them was illuminated with visible light from 76 h to 88 h after ultraviolet irradiation, while the other was kept in the dark before ^{3}H labelling. — — —, Visible light; ———, ultraviolet light.

light these steps may correspond to the formation of gaps in the two newly synthesised strands at adjacent positions and to the *de novo* DNA synthesis detected previously[10,11], although it may still be that the staggered breaks are actually simple nicks made enzymatically, provided that, as claimed by Chiu and Rauth[17], most dimer sites do not involve gap formation after exposure to small amounts of ultraviolet light. The most important part of his model is his proposal that cross-over molecules form by pairing of the two overlapping sectors of the daughter strands of the broken ends. This process effects a crosswise reunion of daughter DNA strands of the two future sister chromatids. In the light of recent findings about the middle repetitive nucleotide sequence in eukaryote DNA[18–20], it is tempting to speculate that such a pairing process may be facilitated by short repetitive nucleotide sequences interspersed between unique sequences.

I thank Drs T. H. Yosida and K. Moriwaki for their advice and discussion.

Molecular basis of control of mitotic cell division in eukaryotes

MITOTIC division in *Physarum polycephalum* is preceded by a marked increase in the phosphate content of very lysine-rich histone (Pp. F1) (ref. 1) due to phosphorylation of serine residues probably at specific points in the amino acid sequence[2,3]. The phosphate content of F1 histone has been measured by a number of groups under a variety of conditions in an attempt to understand the role of F1 phosphorylation and three facts have been established.

First, F1 phosphate content is positively correlated with cell replication rate in calf[4], cultured hepatoma cells[5,6], normal and regenerating rat liver[7] and a variety of rat and mouse tumours[8], giving an important indication that the correlation is universal.

Second, some F1 phosphorylation takes place during S phase. In regenerating rat liver F1 phosphorylation occurs in the few hours before mitosis[7–9] but it is not possible to distinguish, in this system, between S phase and G2 phase and this high phosphate content could not be correlated either with DNA synthesis or with initiation of mitosis. Histone phosphorylation has been studied in cultured mammalian cells synchronised at mitosis using a blocking agent and mitotic selection[10] which gives synchrony through G1 phase and into S phase but not in G2 phase[11]. Pulse labelling experiments have shown increased phosphorylation of F1 in S phase[10]. Different experiments using long term double labelling and the precise natural synchrony in *P. polycephalum* have shown that there is no change in the overall phosphate content per molecule of Pp. F1 during S phase[1].

It is important to determine whether these data are consistent with the mammalian pulse labelling experiments and so the *P. polycephalum* data have been transformed to predict the results of a pulse label experiment such as those carried out in mammalian systems. The transformation (Fig. 1) shows that a peak of phosphorylation, as measured by pulse labelling, would appear in S phase in *P. polycephalum*, in agreement with the mammalian observations. The peak is due to histone synthesis, which requires some phosphorylation to occur in order to maintain the constant overall phosphate content per molecule. These results throw considerable doubt on the significance of the S phase phosphorylation although the possibility that different sites of

phosphorylation are involved cannot yet be ruled out. The doubt has been strengthened recently by studies of the coupling of S phase phosphorylation and DNA synthesis[12], and by the work of Marks *et al.*[13] with synchronous HeLa S-3 cells.

Third, most Pp. F1 phosphorylation occurs in late G2 phase (Fig. 1) and at this time there is also a large increase in overall phosphate content per molecule[1]. Increased F1 phosphorylation has also been observed in mammalian cells in late G2 phase[11], mostly in the 3 h before metaphase [14], exactly in agreement with the *P. polycephalum* results. Further, an increased F1 phosphate content occurs in mammalian metaphase cells[15] and dephosphorylation occurs when these cells move into G1 (ref. 16). These data are consistent with the very precise timing in *P. polycephalum* which located the peak of maximum Pp. F1 phosphate content at the time of chromosome condensation[1] and this is proposed as the initiation step for mitosis[17]. The nuclear F1 histone phosphorylating enzyme activity has been found to peak dramatically at the time during the mitotic cycle when the net rate of phosphorylation of Pp. F1 is a maximum implying that the change in enzyme activity 'triggers' the phosphorylation[17]. Further we have shown that there is a remarkable correlation between the observed changes in enzyme activity and the data in the literature concerning the expected behaviour of the mitotic trigger in *P. polycephalum* and it has been proposed that these events are linked[17]. As a direct test of the proposal, the effect of the addition heterologous F1 histone phosphokinase on the cycle time of the naturally

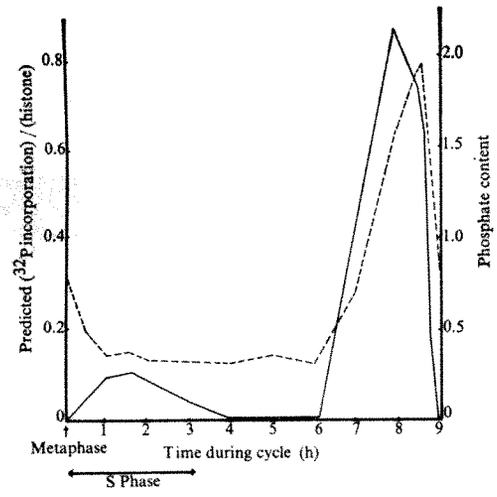

Fig. 1 The pulse length was 1/8 of a generation time in the mammalian experiments[10] which is equivalent to 1 h in the *P. polycephalum* cycle. If the net rate of phosphorylation of F1 is dP/dt then a 1 h pulse would show an incorporation

$\int_{t-1}^{t} (dP/dt)\,dt = P_t - P_{t-1}$ where P_t is the total phosphate content of F1 at time t. The *P. polycephalum* experiments measured $P_t/N_t = \chi_t$, say, where N_t = total number of F1 molecules at time t[1]. The incorporation expected during a 1 h pulse ending at time t is

$$P_t - P_{t-1} = N_t\chi_t - N_{t-1}\chi_{t-1} = N_t\partial\chi + \chi_t\partial N - \partial\chi\partial N$$

where $N_{t-1} = N_t - \partial N$ and $\chi_{t-1} = \chi_t - \partial\chi$. Therefore incorporation per F1 molecule,

$$(P_t - P_{t-1})/N_t = (N_t\partial\chi + \chi_t\partial N - \partial\chi\partial N)/N_t = \partial\chi + \chi_t\partial N/N_t, \text{ neglecting } \partial\chi\partial N$$

The first term, $\partial\chi$, represents incorporation due to a change in the overall phosphate content of the F1 and the second term represents net incorporation due to maintaining the overall phosphate content per molecule constant in the face of synthesis of new F1. Any turnover of F1 phosphate would raise the level of the curve but this has been ignored. N_t and ∂N were estimated for *P. polycephalum* by assuming a constant ratio of Pp. F1 histone synthesis to main band nuclear DNA synthesis[25] and using published data on DNA synthesis[16]. χ_t and $\partial\chi$ were obtained from our previous measurements of Pp F1 phosphate content[1]. ———, Calculated phosphorylation (simulated label experiment); — — — measured phosphate content[1].

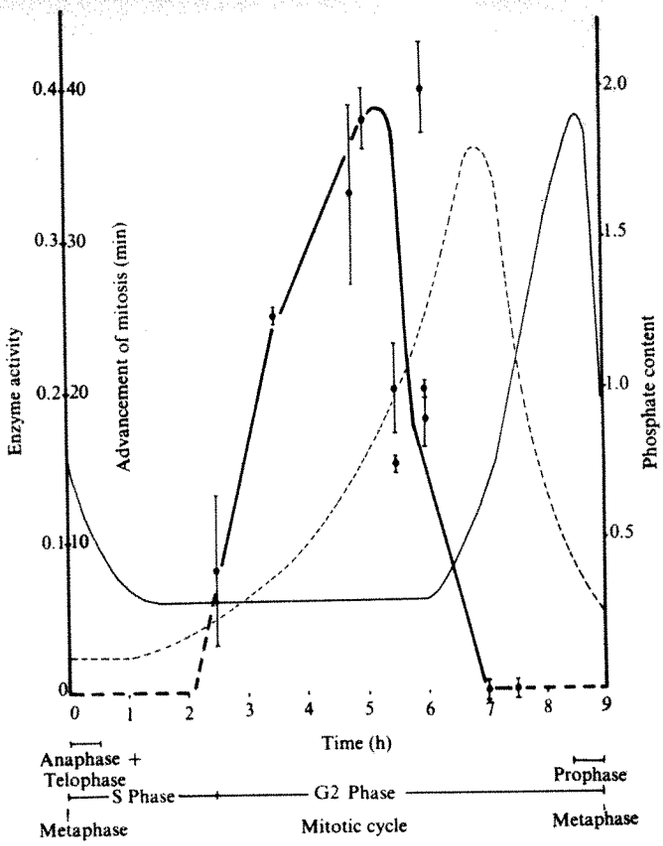

Fig. 2 Synchronous plasmodia of *P. polycephalum* were prepared by fusion of microplasmodia on filter paper and grown at 26° C in the dark[27]. At a known time between mitosis 2 (the second mitosis after fusion) and mitosis 3, the filter paper was cut into quarters and transferred to Petri dishes. Each culture constituted a complete experiment with its own control, conducted in duplicate. Duplicates of the same plasmodium divided within 5 min of each other. Plasmodia were treated by carefully pipetting on their surface 0.1 ml of solution. Enzyme solutions, containing approximately 1.5 mg ml^{-1} protein had been dialysed overnight against 0.02 M Tris HCl buffer *p*H 7.2 (ref. 19). The treated plasmodia were starved for 1.5 h to facilitate absorption[19]. Fresh medium was then added and the time of the third mitosis determined by microscopic examination of glycerol/ethanol fixed smears under phase contrast[28]. Advancement of mitosis by F1 phosphokinase is shown as a function of the time in the cycle when the enzyme was added, (●—●) with the errors calculated from the differences between duplicates as in Table 1. For comparison, the level of endogenous enzyme activity[17] (— — — —) and Pp F1 phosphate content (————) are also shown together with the timing of the main events in the *P. polycephalum* mitotic cycle[26].

synchronous cultures of *P. polycephalum* has been investigated.

F1 histone phosphokinase was prepared by extraction of Ehrlich ascites cell chromatin with 0.4 M NaCl, followed by ammonium sulphate fractionation of the extract in the presence of 10^{-5} M cyclic AMP. The protein precipitating between 17.5 and 35% saturation was collected and dissolved in 0.4 M NaCl, 0.01 M Tris *p*H 7.5. The enzyme activity is similar to that described in metaphase arrested cells by Lake[18]. It phosphorylates F1 *in vitro* mainly in the N and C terminal regions at sites whose phosphorylation is associated with growth. It does not require cyclic AMP. The The preparation contains only traces of F1 histone kinases, HK_1 (cyclic AMP dependent) and HK_2 (cyclic AMP independent)[2].

Heterologous enzyme was used because of its availability and because the general features of the process are almost certainly universal. Work is in progress to obtain and use pure homologous and heterologous enzyme, but this is a

long term project.

For each *in vivo* experiment at least two plasmodia of *P. polycephalum* were used. One was not treated in any way and was used as a control for measurements of the normal cycle time. The second was cut into four approximately equal 90° segments at a known time after its second mitosis. Two segments were treated with a blank solution and two with the enzyme solution. The four segments were starved for 1.5 h and then transferred to fresh growth medium (for experimental details see Fig. 2 and ref. 19). Provided the enzyme was added at the correct time in the cycle the enzyme treated segments entered mitosis precisely together up to 40 min before the blank treated duplicate segments which themselves entered mitosis precisly together. The rate of progression through mitosis itself was not affected. The effect of adding the enzyme at different times during the cycle is shown in Fig. 2. This curve correlates with the time course of F1 phosphorylating activity in *P. polycephalum* nuclei, since at about 2 h before mitosis this activity falls off sharply and adding enzyme is found to have no effect, either because the added enzyme is also inactivated or because the enzyme activity is no longer needed by the nucleus. Moreover, added enzyme is most effective when the endogenous enzyme is at one-third to two-thirds of its maximum level. The ineffectiveness of added enzyme early in the cycle is probably due to its instability or to some other preparation for mitosis, such as DNA synthesis, not being complete. The correlation of time of enzyme addition for maximum effect with the previous measurements of endogenous enzyme activity provides strong support for the contention that the observed effect is due to a specific action of F1 phosphokinase and is not a general growth promotion.

The *in vitro* activity of the actual enzyme preparations used for the experiments of Fig. 2 was assayed directly using calf thymus F1 histone as substrate. The specificity of the enzyme for F1 histone in chromatin was demonstrated by incubating calf thymus chromatin in 5 mM $MgCl_2$+50 mM tris-HCl *p*H 7.5 with γ^{-32}P-ATP. In the absence of added enzyme, extensive phosphorylation of nonhistone proteins occurred but no histone phosphorylation was observed. In the presence of added enzyme reduced phosphorylation of nonhistone proteins occurred and a large incorporation of ^{32}P into F1 histone, but not into other histones, was observed[20]. The significance of the reduced incorporation into nonhistone proteins is unknown but the enzyme clearly phosphorylates specifically F1 histone, in chromatin. It is just conceivable that the unpurified F1 phosphokinase preparation contained some other substance or combination of substances which produced the effects reported (Fig. 2). This possibility can be ruled out completely only by the use of pure homologous F1 phosphokinase. However, some control experiments have been caried out to check if such a coincidence is likely. The enzyme after dialysis against 0.02 M Tris *p*H 7.2, can be specifically inactivated by storage for 2 weeks at 4° C or by freezing and thawing four times. Such inactivated enzyme preparations have no effect on the timing of mitosis. Albumin and creatine phosphokinase are also without effect (Table 1). Positive results have only (and always) been obtained with active F1 phosphokinase preparations. Further progress on these lines must await the availability of pure enzyme.

Taken together with the previously reported data on Pp. F1 phosphate content[1], chromatin condensation (for example ref. 21), F1 phosphorylating activity in *P. polycephalum* nuclei[17] and the mitotic trigger[22–24], the results reported here provide direct evidence for our previous proposal that F1 phosphokinase triggers an increase in F1 phosphate content which is the initiation step in mitosis. Acceleration of initiation of mitosis has been shown before, by plasmodial fusion[22,23], ultraviolet irradiation[23] and plasmodial extracts[19] but this is the first successful attempt to accelerate the initiation of mitosis by a specific substance, F1 histone phosphokinase. The data already accumulated on the mechanism of this control process mediated by F1 phosphokinase fit into a consistent hypothesis (unpublished), and experiments are in progress to test it further and clarify the details. It is interesting that this process probably applies to cancer as well as normal cells.

Calf thymus chromatin was provided by P. G. Boseley. T. A. L. visited Portsmouth as a Senior Visiting Fellow of the Science Research Council. The work was supported by grants from the Cancer Research Campaign and the Science Research Council.

Inhibitor of protein synthesis isolated from ribosomes of unfertilised eggs and embryos of sea urchins

IT is not yet clear what mechanisms turn on protein synthesis in the first stages of embryonic development. In the sea urchin two mechanisms are debated: activation of ribosomes[1,2] and activation of mRNA[3,4], possibly through adenylation[5,6]. An inhibitor of protein synthesis has been isolated from ribosomes of unfertilised eggs of *Paracentrotus lividus*[7,8] by extraction of ribosomes with high concentrations of salt. Metafora *et al.*[7] found that this inhibitor is a protein, that it is not a ribonuclease and that it decreases ribosomal binding of a synthetic messenger (poly(U)) and of phenylalanine tRNA. They found that this inhibitor was absent from extracts of ribosomes of *P. lividus* blastulae, suggesting that it is inactivated or lost when the eggs are fertilised.

In view of the importance of such a finding for understanding the restriction of protein synthesis in unfertilised eggs, I have investigated similar inhibitors from eggs and embryos of *Strongylocentrotus purpuratus*, and determined the distribution of inhibitor between monoribosomes and polyribosomes of echinoid embryos. While confirming the occurrence of inhibitor in unfertilised eggs, I have found it in embryos as well, particularly in monoribosome fractions.

Ribosomal extracts were tested for inhibitory potential in protein synthesis in a cell-free system using both endogenous mRNA and poly(U). Extracts were prepared from ribosomes of unfertilised eggs and blastulae by the method of Metafora *et al.*[7] using 1 M NH_4Cl. Protein synthesis was measured as incorporation of ^{14}C-phenylalanine in an *in vitro* system containing ribosomes from either unfertilised eggs or blastulae. Only blastula ribosomes had enough natural mRNA attached to give detectable endogenous synthesis (Table 1, experiment 2). Endogenous incorporation with these ribosomes was inhibited strongly by either of the ribosomal extracts (Table 1, experiment 1). Incorporation with ribosomes from both unfertilised eggs and blastulae was stimulated strongly by addition of poly(U). This stimulation was inhibited by ribosomal extracts from both unfertilised eggs and blastulae.

Table 1 Effect of ribosomal extracts on cell-free protein synthesis directed by endogenous mRNA and poly(U)

Type of mRNA	Source of extract	*in vitro* ^{14}C-phenylalanine incorporation (c.p.m. per assay)	
		Using egg ribosomes	Using blastulae ribosomes
Experiment 1			
Endogenous mRNA	none	—	6,520
,,	UF egg ribosomes*	—	2,516
,,	blastula ribosomes†	—	2,620
Experiment 2			
Endogenous mRNA	none	0	3,740
,, + poly(U)	none	7,430	21,500
,, + ,,	UF egg ribosomes‡	48	4,940
,, + ,,	blastula ribosomes§	200	5,860

Eggs and sperm of *Strongylocentrotus purpuratus* were collected and cultivated[19]. Ribosomes and their 1 M NH_4 Cl extracts were prepared as described by Metafora *et al.*[7] except that triethanolamine-HCl (K and K Laboratory, Inc.) was substituted for Tris HCl. The ribosome and extract solutions were stored at −80° C. A *p*H 5 fraction prepared from rat liver supernatants[3] contained aminoacyl activating enzymes, tRNA, amino acids, and soluble enzymes. The *in vitro* assay mixture contained in 250 μl: 0.1 M KCl, 5mM $MgCl_2$, 0.05 M triethanolamine-HCl (*p*H 7.4), 6mM mercaptoethanol, 2.5 mM ATP, 0.2 mM GTP, 4 mM 2-phosphoenol pyruvate, 0.35 μg pyruvate kinase, 0.31 μg ^{14}C-L-3-phenylalanine (5.3 mCi mmol^{-1}), *p*H 5 fraction from rate liver at optimal concentrations (about 30 μl containing about 0.8 mg protein), 2.6 A_{260} units (defined in Fig. 1) of ribosomes, ribosomal extract, 46 μg *, 42 μg †, 58 μg ‡, and 23 μg §, or a compensating buffer and sometimes 50 μg (poly(U)). The reaction mixture was incubated with vigorous shaking for 60 min at 27° C, stopped by the addition of 3 ml of ice-cold 6% trichloroacetic acid (TCA) containing L-phenylalaline, incubated for 10 min at 90° C, chilled in ice, filtered onto membrane disks, then washed with 6% TCA, dried, and counted in a toluene based scintillant. The assay was linear for 50 to 60 min with poly(U) as the messenger and for 20 min with endogenous blastula messenger. Protein content was estimated by the method of Lowry *et al.*[20].

As the inhibitor could have a regulatory function in development, I have measured its concentration in sea urchin eggs and embryos at various stages. High salt extracts from ribosomal pellets were prepared simultaneously from unfertilised eggs, 32-cell morulae, 500-cell blastulae (B1-500) and early mesenchyme blastulae (B1My-1), by the method of Metafora *et al.*[7] (Fig. 1). Extracts from ribosomes of all early stages were inhibitory. Extracts from equal quantities of ribosomes were progressively less inhibitory when taken from embryos of increasing age. I found that extracts of blastula ribosomes contained about half as much protein as those from unfertilised egg ribosomes. When relative incorporation was plotted against the amount of protein in each extract, the inhibition by extracts from the various stages was similar (Fig. 2). Since there is little change in the total number of ribosomes from fertilisation until mesenchyme blastula stage (about 25 h at 14° C), I conclude that there is a continuous decrease in the amount of extractable inhibitor per embryo during this time.

The ribosomal extracts from these early stages were resolved into between 9 and 11 protein bands on 6 M urea electrophoretic gels[10]. Seven of these bands were common to

extracts of unfertilised eggs, morulae and blastulae, and I do not know which might have inhibitory activity.

Previous studies have shown that the polyribosome: monoribosome ratio increases after fertilisation of sea urchin eggs and increases throughout the blastula stage[11,12]. To see if there was any correlation between the observed amounts of extractable inhibitor and the polyribosome: monoribosome ratio of these embryos, I prepared monoribosomes and polyribosomes of blastulae by sucrose gradient centrifugation. Embryos were homogenised in 0.2 M salt[13] instead of the 0.4 M salt of Fig. 1. With the lower concentration of salt fewer nonribosomal ribonucleoprotein particles (RNP particles) cosedimented with the monoribosomes and small polyribosomes. The high speed pellets of these fractions were used to prepare the extracts whose inhibitory capacity is shown in Fig. 3. The points for the unfertilised egg extract from Fig. 1 are included for reference although those ribosomes were isolated using different salt concentrations. To obtain an equivalent amount of inhibition by monoribosome and polyribosome extracts, almost three times as many polyribosomes as monoribosomes were needed. For example, 2.4 A_{260} units (defined in Fig. 1) of monoribosomes or 6.7 A_{260} units of polyribosomes gave 40% inhibition.

To determine whether this inhibitor is absent from non-embryonic tissues, extracts were prepared from the ribosomes of adult rat liver, which are known to contain about 90% polyribosomes[14]. The effect of these extracts on *in vitro* synthesis of proteins is given in Fig. 3. I found that ribosomes from adult rat liver contained little extractable inhibitor, about 0.1 that of blastulae ribosomes. In summary, Fig. 3 shows that high salt extracts of blastula monoribosomes contain substantially more extractable inhibitor than those of polyribosomes, implying that *in situ* the monoribosomes are inhibited, and that the inhibitor is more abundant in eggs and embryos than in adult tissue.

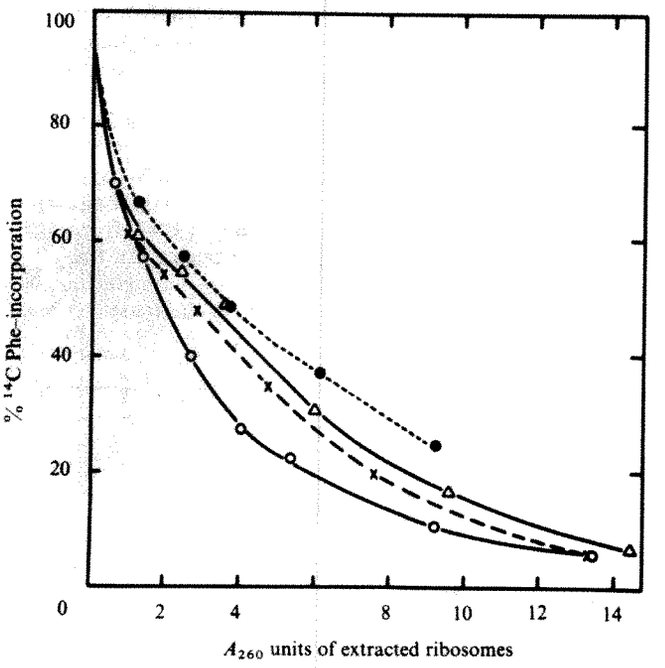

Fig. 1 Quantitative determination of the inhibitory capacity of ribosomal extracts from unfertilised eggs and embryos. The percentage of ^{14}C-phenylalanine incorporation stimulated by poly(U) plus endogenous mRNA is plotted against amounts of ribosomal extracts taken from known quantities of ribosomes. Methods were as described in Table 1 except that for the assays 1.2 A_{260} units of morula ribosomes were added and the incubation time was 45 min. The amount of ribosomal extract varied as noted in the abscissa. The quantity of extract added is measured by the 260 nm absorbance of the ribosomes from which they were taken. This absorbance was measured after the ribosomal pellet had been stirred overnight at 4° C in 1 M NH_4Cl, and after the unsuspended material had been removed by low speed centrifugation. According to convention, 1 A_{260} unit of ribosomes equals the absorption of ribosomes if they were contained in 1 ml and read in a 1 cm cuvette at 260 nm. Ribosomal extracts from unfertilised eggs (0); from 32-cell morulae (×); from 500-cell blastulae (△); and from hatched blastulae at stage B1My-1[21] (●).

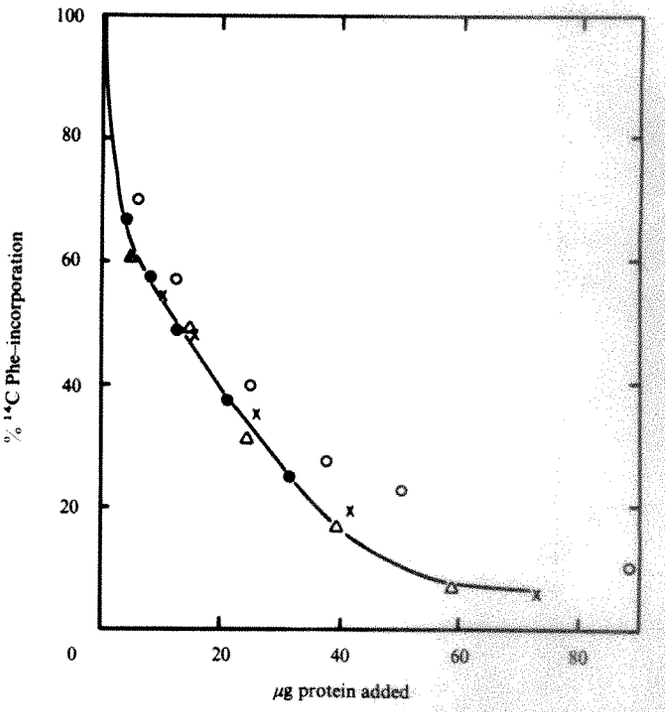

Fig. 2 Inhibition of ^{14}C-phenylalanine incorporation per μg of protein added from ribosomal extracts. Observations and notations are as in Fig. 1. The protein concentration was estimated by a micro Biuret method[25].

Preliminary results with RNP particle-enriched fractions do not rule out the possibility that RNP particles which cosediment with monoribosomes also contain inhibitory proteins. The presence of an inhibitory protein on preformed messages in such particles could prevent their attachment to ribosomes or their translation once attached.

Ribosomal extracts were tested for possible RNase activity by Ball's method[15]. Extracts from unfertilised eggs and blastulae containing 20–40 μg of protein, sufficient to inhibit amino acid incorporation by 60–85%, had less than 1×10^{-10} g RNase. Extracts of rat liver ribosomes sufficient to inhibit amino acid incorporation by 15% also contain negligible amounts of RNase. The rat liver supernatant fraction used in the assays contributed about 2.5×10^{-10} g of RNase. It is unlikely that any observed inhibition is due to RNase activity, for the amount of RNase activity did not correlate with the percentage of inhibition.

The inhibitor is not a GTPase since increasing the amounts of GTP two- and six-fold did not alter the amount of inhibition.

What is the normal function of this inhibitor? While these results and those Metafora *et al.*[7] and Gambino *et al.*[8] agree in demonstrating the existence of the inhibitor, these authors indicate that the inhibitor disappears after fertilisation, thereby triggering activation of protein synthesis. In contrast, I have found a gradual diminution in the amount of inhibitor. Therefore, I suggest that this slow loss of inhibitor is responsible for the continuous increase of rate of incorporation of labelled amino acids seen until mesenchyme blastula or early gastrula[16–18]. The inhibitor seems to be acting at the monoribosome level, so that a

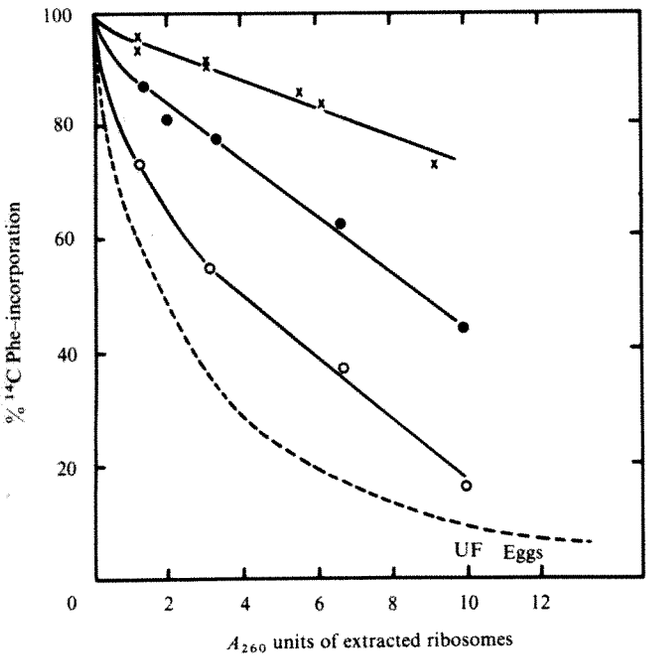

Fig. 3 Inhibitory potency of extracts from different ribosomal fractions, and from adult rat liver. Embryos were slightly older than any described in Fig. 1, being stage B1My-2/Ga-1[21]. Homogenisation and sucrose gradient preparation of monoribosomes and polyribosomes were described by Hogan and Gross[13]. Rat liver ribosomal pellets were prepared as described by Stavy and Gross[3]. Extracts were prepared as described in Table 1. Assay conditions and quantification were as described in Fig. 1. Ribosomal extracts from monoribosomes (O); from polyribosomes containing from 4 to 25 ribosomes per polysome (●); and from rat liver ribosomes (×); unfertilised egg extract of Fig. 1 (- - - -).

gradual loss of inhibitor with time would also account for the continuous increase in the polysome:monoribosome ratio until the mid-blastula stage[11,12].

I thank Dr Arthur H. Whiteley for discussions, encouragement and facilities. This work was supported by a grant from the US National Science Foundation to Dr Whiteley.

Stability of the nucleoside composition of tRNA during biological ageing of mice and mosquitoes

IN several organisms, alterations in tRNA have been reported to occur during physiological changes. Both qualitative and quantitative changes have been demonstrated in isoaccepting species of various tRNAs[1-4]. Chromatographic changes have often been attributed tc changes in nucleoside composition. In *Drosophila*, changes in the chromatographic patterns of certain tRNA species at different developmental stages have been correlated with an enzymatic alteration producing a minor nucleoside, Q[4]. Such differences could be involved in control of protein synthesis at the translational level directly by tRNA species, and (or) in regulation of protein activity by interaction of tRNA with a previously formed protein[5,6].

During an investigation of the role of translational macromolecules in biological ageing, column chromatography of aminoacyl-tRNAs from 'mature' and 'old' adults of *Aedes aegypti* revealed variations in patterns of certain isoaccepting tRNAs[7]. A similar study on aminoacyl-tRNA from ageing mice revealed no chromatographic changes[8]. In the liver of ageing rodents, including mice, however, glycine N-methyltransferase activity was reported to increase[9]. It was

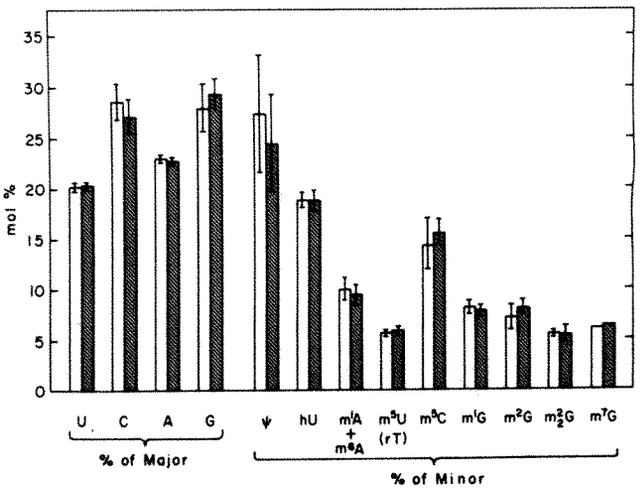

Fig. 1 Nucleoside composition of tRNA from mature and old mosquitoes. Nucleoside compositions were determined by the chemical labelling technique as described in the text. Values plotted are mean ± s.d. for four determinations on each age with the exception of m⁷G, for which only two analyses were done on mosquito tRNA. Minor/major ratios: mature, 0.109±0.005; old, 0.106±0.004. Open columns, mature (10-d-old); hatched columns, old (30-d-old) adult female *Aedes aegypti*.

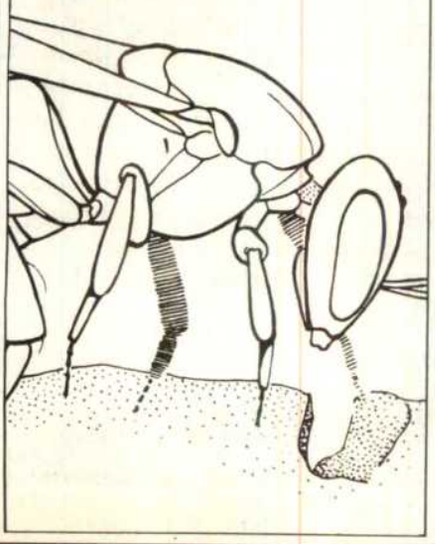
NATURE'S WONDERS EXPLORED.

The Social Behavior of the Bees



Charles D. Michener

The first systematic account of social behavior in all groups of bees, this is at once a broad survey and a specific and critical guide to the literature.

Michener describes all levels of social organization among bees, their communication, division of labor, nest structure, evolution, reproduction, and much more.

This book comprises virtually everything known about the social bees.

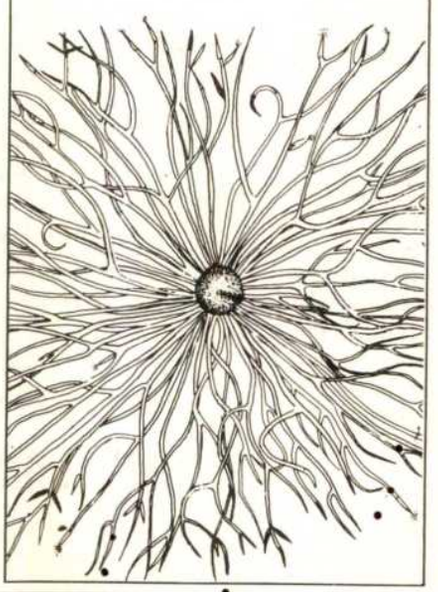
On Development



The Biology of Form

John Tyler Bonner

In an elegant study of complex and elusive problems, John Bonner examines the biology of morphogenesis, maturation, senescence, and death. And evaluates various approaches to a unified theory of development.

Synthesizing contributions from many fields of biology, Bonner views the concept of the life cycle from both evolutionary and biochemical perspectives.

Corn

Its Origin, Evolution, and Improvement

Paul C. Mangelsdorf

This is the story of a lifetime of research on one of the most familiar, and most mysterious, of grains, as well as a comprehensive study of maize biology.

Mangelsdorf takes his reader from archaeological digs to experimental garden plots and the laboratory bench. He draws on botany, genetics, cytology, archaeology, and history for evidence about the origin and evolution of corn, the most important food plant of the New World.

Plant ecology is basic to general, animal, systems, paleo-, and human ecology. Plants are the primary producers; they dominate the flow and cycling of energy, water, and mineral nutrients within ecosystems.
The structure of the vegetation which plants form determines much of the character of the landscapes in which other organisms, including men and women, live and prosper. If we know why plants grow where they do, we know a good deal about why organisms other than plants live where they do.
This volume concentrates on descriptions of kinds of zonal vegetation into which eco-physiological data must fit. It presents this information in a consistent frame of reference and suggests where more factual data are needed.
An excellent introduction to plant eco-physiology, it analyzes past research in the field and makes clear how much more investigation must be undertaken to describe plant and vegetation structure and function, their correlations, and their relationships to environment.

the vibrator to keep cells and small particles in suspension

A vibrative action to keep cells and small particles in suspension, either by using micro-titration plates for small amounts of cells and fluid or small conical flasks where larger quantities are required. The cells may then by pipetted direct from the vibrator thus saving time and effort of repeated shaking and allowing a continuous quality control to be achieved. The correct speed can be selected, depending on the type of cells or particles being used. Variable speed up to about 3,500 vibrations per minute.

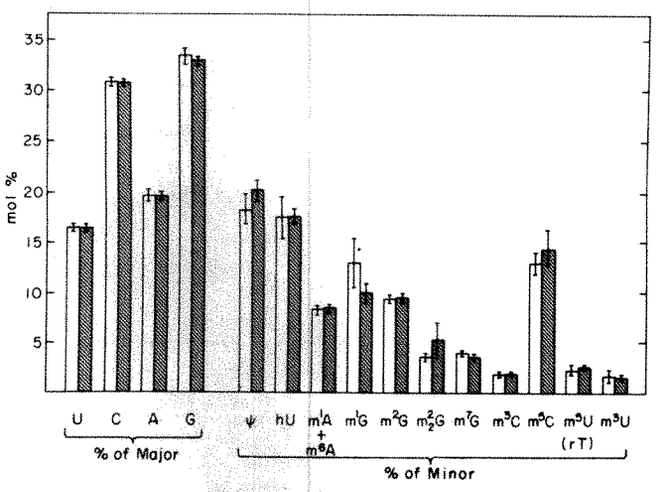

Fig. 2 Nucleoside composition of tRNA from mature and old mice. Determined as in Fig. 1. Minor/major ratios: mature, 0.190±0.013; old, 0.193±0.010. Open columns, mature (12 months old); hatched columns, old (30 months old) female C57BL/6J mice.

suggested that this could lead to undermethylation of tRNA in ageing animals by depletion of S-adenosylmethionine, and by production of S-adenosylhomocysteine which inhibits tRNA methyltransferases[10].

With these observations as background, we have investigated the nucleoside composition of tRNA from mature and old C57BL/6J mice and *Aedes aegypti* to determine if there is any change in this parameter as mature animals age. On the basis of survivorship curves, we have defined mature mosquitoes as 10-d-old adults, and mature mice as 12 months old. Old animals are from the 50% survivorship level, being 30 d for adult mosquitoes and 30 months for mice.

Samples of tRNA were prepared from whole mosquitoes and from mouse liver by phenol extraction, DEAE-cellulose chromatography, and Sephadex G-100 gel filtration. Purity of the preparations was assessed by electrophoresis on polyacrylamide gels and subsequent ultraviolet scanning. All preparations were at least 90% tRNA, the principal contaminant being 5S rRNA.

Nucleoside composition analyses were carried out by chemical tritium labelling exactly as described by the Randeraths (ref. 11 and references therein). We were able to quantitate 13 components in mosquito tRNA and 15 in mouse liver tRNA. Inosine seemed to be present in both organisms, but on our chromatograms it was overlapped by the guanosine trialcohol spot and is included with guanosine. A portion of 1-methyladenosine is converted to N^6-methyladenosine during the analysis, and so these two components were combined in the calculation of composition.

Inspection of fluorograms showed no discernible qualitative differences in nucleoside composition during ageing, that is the same nucleosides were present in tRNA from mature and old animals (data not shown). Figures 1 and 2 show that there are also no significant age-related quantitative changes in tRNA nucleoside composition nor in degree of tRNA modification in the two animal models studied.

It seems remarkable that, at a time when the population has declined physiologically to the point of highest mortality rate, the complex enzyme systems necessary for tRNA maturation are still producing a fully modified product. This indicates that the nucleoside composition of tRNA is an important and tightly regulated parameter for a given organism, or organ therein.

Our results argue against tRNA modifying enzymes having a role in biological ageing. They also point up the danger of interpreting chromatographic changes in tRNA or changes in activity of tRNA methylases in terms of the final degree of modification without actually analysing the tRNA.

Relationship between tritiated poly-L-lysine binding and template activity of human chromosomes

IT has been reported that cytological preparations of chromosomes can serve as templates in RNA polymerase reactions[1,2]. The newly synthesised RNA on chromosomes was readily digested with RNase in contrast to RNA which was synthesised in a similar manner but using as a template denatured DNA immobilised on nitrocellulose filters[1]. When cytological preparations of chromosomes were pretreated with poly-L-lysine (PL), no synthesis of RNA could be demonstrated[2]. The implication was that bound PL blocked those sites on DNA template which were responsible for transcription.

We used human metaphase spreads prepared by a standard technique[3] as templates for RNA synthesis and for binding tritiated poly-L-lysine (^{3}H-PL). We wished to establish whether both of these processes occur on the same or on different segments of chromosomes. Typical karyotypes of metaphase chromosomes with bound ^{3}H-PL or bound ^{3}H-RNA are shown in Fig. 1. The results of the labelling are summarised in Table 1. In both sets of experiments over 98% of total grains was located over the chromosomes and the remainder over the background. Analysis of a large number of karyotypes (over 100 in total) indicated that the labelling of chromosomes was reproducible (Table 1). Those sites on A chromosomes that have highest template activity also show a high affinity for ^{3}H-PL. Although structural organisation of chromosomes necessary for both functions is not known in detail[2,4], it is likely that relatively exposed segments of

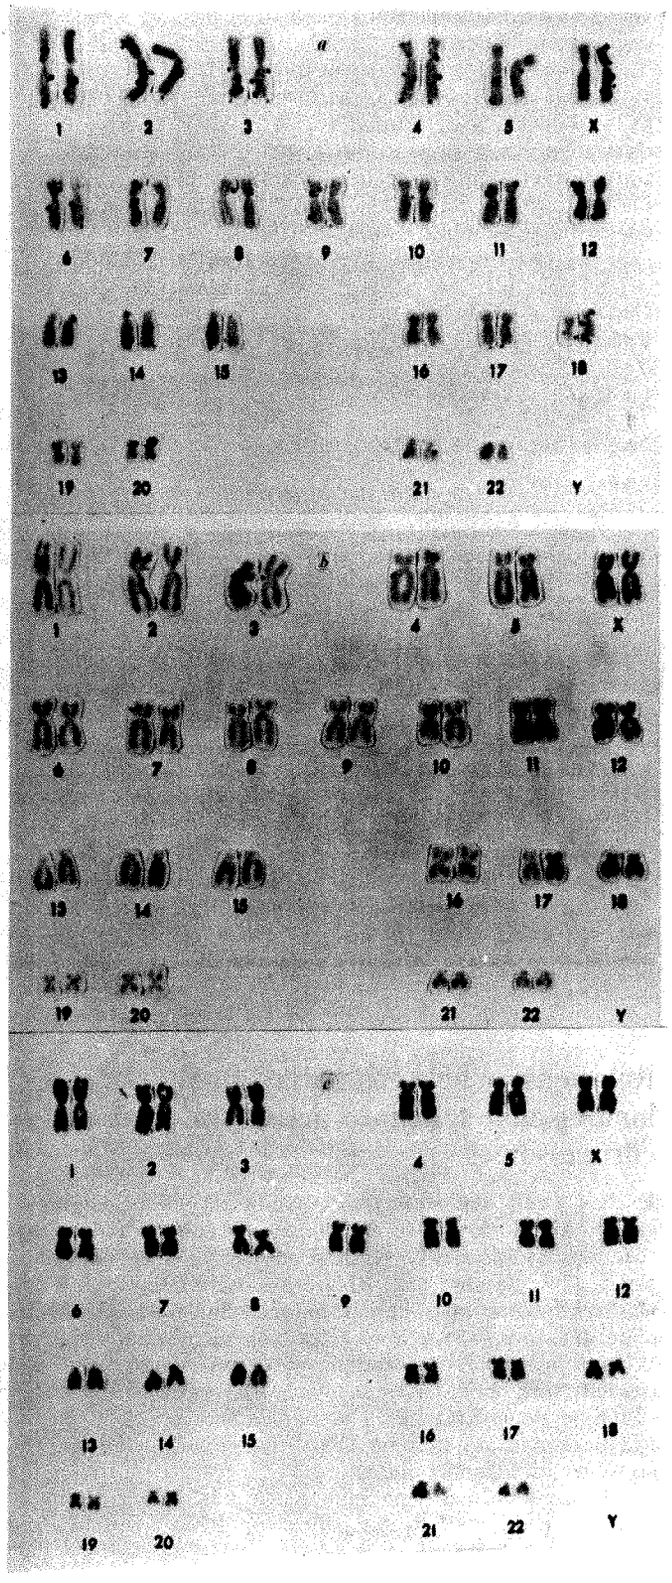

Fig. 1 Typical karyotypes of treated and control human metaphase chromosomes. *a*, Chromosomes treated with tritiated poly-L-lysine (^{3}H-PL); *b*, chromosomes used as templates in RNA polymerase reaction; *c*, chromosomes subjected to conditions of RNA polymerase reaction without the polymerising enzyme. Tissue culture of human circulating lymphocytes and the preparation of metaphase spreads was done according to a standard procedure[2]. Slides containing chromosomes were treated with ^{3}H-PL (molecular weight 50,000–100,000, specific activity 3.32 x 10^3 c.p.m. mg^{-1}) as follows. 0.1 ml of 0.1% ^{3}H-PL solution in 0.1. N acetic acid was applied and the slide was covered with a cover slip. After 20 min at room temperature the cover slip was removed, the slide washed with water and dried. After exposure to NTB-2 emulsion for 7 d, the slides were examined under a microscope. The grouping of metaphase chromosomes according to the degree of contraction was based on the measurement of A_1 chromosome (short, 8.3 μm; medium, 10.0 μm; long, 12.5 μm). Identification of individual chromosomes was aided by the application of a Giemsa banding procedure after treatment of chromosomes with trypsin[7,8]. RNA polymerase reaction was done on slides containing metaphase spreads (without any pretreatment) essentially according to the published procedure[1]. ^{3}H-UTP labelled at C5 of the uracil base (specific activity 41.7 Ci mmol^{-1}) was used for RNA labelling. In the control experiments, all the ingredients of the reaction, except the *E. coli* RNA polymerase (specific activity 240 units mg^{-1} assayed in standard conditions), were present. The slides were analysed for grains as described for ^{3}H-PL binding.

Table 1 A comparison of ^{3}H-poly-L-lysine binding, RNA synthesis and quinacrine fluorescence of human A group chromosomes

Chromosome segment	^{3}H-PL binding G	ΔG	RNA synthesis G	ΔG	Quinacrine fluorescence
A_1e	9.33	−8.87	0.48	1.30	3.20
A_1m	4.12	1.40	0.40	0.20	40.00
A_1c	13.22	−9.43	—	—	3.20
A_2es	15.00	−10.87	—	—	1.20
A_2ms	8.34	6.80	1.00	−1.00	16.40
A_2c	12.29	14.80	—	—	4.10
A_2ml	9.57	−0.50	0.37	—	32.7
A_2el	24.50	−42.87	3.20	−12.00	1.20
A_3e	11.38	−8.33	0.25	—	4.4

A_3c	9.42	2.87	1.95	—	(7.2)

Average number of grains per unit weight (g × 10^{-15}) of a given chromosome segment[6] (G) was determined separately for karyotypes containing short, medium or long metaphase chromosomes (Fig. 1). For A_1 and A_3 chromosomes in which short and long arms could not be distinguished, the data are given for the combined two end and two middle segments. Forty-six karyotypes (16 short, 16 medium, 14 long) were analysed for ^{3}H-PL binding and 34 (11 short, 12 medium, 11 long) for RNA synthesis. The data are averages obtained with the three classes of chromosomes. The probable error computed for several groups of karyotypes belonging to the same class ranged from 15–30% of the mean value. The differences in G for each chromosomal segment between chromosomes of different length (ΔG) was also computed ($\Delta G = (G_{long} - G_{medium}) + (G_{long} - G_{short}) + (G_{medium} - G_{short})$) to show the effect of chromosomal contraction on the content and distribution of grains. The integrated intensity of quinacrine mustard fluorescence for different chromosomal segments (given in arbitrary units) was determined by measuring the corresponding areas under the fluorescence curves[5]. The value assigned to A_3c segment may vary since this is a polymorphic region[4] of A_3 chromosome.

nucleic acids are required. On the other hand, the chromosomal segments with high template activity show little fluorescence after treatment with quinacrine mustard[5]. We also observed that both functions depend on the degree of chromosomal contraction. This effect was especially pronounced for the long arm end segment of A_2 chromosome. It did bind more ^{3}H-PL and functioned better as a template when the chromosome was in a more contracted form.

Lac repressor can be fused to β-galactosidase

GENETIC analysis of *i* gene mutants which had lost the capacity to bind operator but not inducer suggested that *lac* repressor binds with its amino terminus to *lac* operator[1]. Here we will show that the carboxy terminus of *lac* repressor is dispensable. We found fusions between the *i* (*lac* repressor) and *z* (β-galactosidase) genes (Fig. 1) which produce fully active *lac* repressor covalently linked to active β-galactosidase.

Such fusions are found among spontaneous *lac*$^+$ revertants of an *Escherichia coli* strain carrying the mutations i^q and z^-_{u118}. i^q stands for a mutation in the *i* promoter which leads to a ten-fold overproduction of *lac* repressor[2]; z_{u118} is a strongly polar nonsense mutation located near the *lac* operator[3]. The *lac*$^+$ revertants of $i^q z_{u118}$ fall into two classes: inducible revertants (due to direct reversion or unlinked suppression) and mutants that produce β-galactosidase at a low constitutive level. These last mentioned mutants have all the characteristics of *i z* fusion: They can be neither induced by inducer nor repressed by a functioning *i* gene in trans. The amount of β-galactosidase made depends on the nature of the *i* gene promoter. Most of these mutants (101 out of 111) no longer produce functioning *lac* repressor. In these mutants part of the structural *i* gene is deleted. In the extracts of ten mutants, however, we found *in vitro* inducer and operator binding. We concentrated our interest on these mutants: Mapping proved that only two of these ten deletions definitely entered the structural part of the *i* gene and that eight others might end in a region of the *i* gene which is still transcribed but not translated (Fig. 1). The β-galactosidase of most of the strains was more heat labile than β-galactosidase from a wild type strain.

We used antibodies against *lac* repressor (anti-repressor) and against β-galactosidase (anti-galactosidase) to decide whether *lac* repressor was fused to β-galactosidase. There is no cross reaction between these antibodies and antigens; however, both anti-repressor and anti-galactosidase precipitate β-galactosidase and *lac* repressor from extracts of fusion 71–56–14 (Table 1). This result strongly suggests, but does not prove, covalent fusion between *lac* repressor and β-galactosidase.

The pure material we needed to settle the question was obtained in the following way: We used extracts of promoter mutant i^{q1} (Müller-Hill, unpublished) from one of the strains (71–56–14) as starting material; ammonium sulphate, phosphocellulose and Sepharose 6B were used for purification. We followed both β-galactosidase and repressor activity throughout the purification steps. There is a good correlation, although not a precise one, between the specific activities of *lac* repressor and β-galactosidase throughout the purification (Table 2). The elution profile of the phosphocellulose column shows several fractions which have simultaneously β-galactosidase and repressor activity. The main fraction was further purified on Sepharose 6B. SDS-gels showed that it was at least 90% pure (Fig. 2). The subunit molecular weight is about 155,000 since our protein runs together with the β-subunit of RNA polymerase from *E. coli*. If we assume β-galactosidase to have the most plausible subunit molecular weight of 125,000 (ref. 9) and *lac* repressor a molecular weight of 37,000 (ref. 10), not much has been lost from β-galactosidase and repressor through the fusion. The repressor-galactosidase was derived from a strain that carried a new strong promoter mutation i^{q1}. We sequenced the N terminus, using the SDS-dansyl-Edman procedure[11] and found it to be identical to the N terminus of lac repressor[1,12]: H_2N-Met-Lys-Pro-Val-Thr-Leu, thereby proving again the covalent fusion and excluding an effect of the promotor mutation i^{q1} on the aminoterminal sequence.

Sequence analysis of *lac* repressor[10] had shown that older results[1] with carboxypeptidase B, which seemed to indicate the necessity of an intact C terminus for operator binding activity, were wrong. Our present results show clearly that

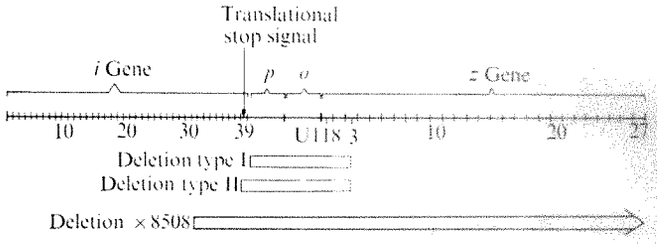

Fig. 1 Genetic map of the i gene, the promoter (*p*), operator (*o*), and the *z* gene. The *i* gene is divided in 39 deletion groups[4], the *z* gene in 27 deletion groups[5]. They are not drawn to scale. Deletion x8630 defines deletion group 39, deletion x8636 deletion group 38 of the *i* gene. Point mutants have been found which recombine with x8630 (Gho, personal communication), indicating that the translational stop signal of the *i* gene falls in deletion group 39. The fusions we found still to have *lac* repressor activity, are either of type I (71–56–9; 71–68–14; 28; 32; 34; 47; 48; 51), or of type II (71–56–14; 71–56–17). Mapping was done as in ref. 4. In some fusions (71–56–14; 17; 71–68–14; 28; 32) i^q was crossed out and i^+ back in using deletion x8508 (ref. 6). These i^+ derivatives of the fusion strains were used to see how deep the deletions entered the *z* gene. Those fusions which were tested (71–56–14 and 71–68–14; 28; 32) did recombine with a nonsense mutant mapping in deletion No. 3 but not with another mapping in deletion No. 1.

Table 1 Results of adding antibodies against *lac* repressor and β-galactosidase in two strains of *E. coli*

strain	anti-repressor added		anti-galactosidase added	
	% *lac* repressor precipitated	% β-galactosidase precipitated	% *lac* repressor precipitated	% β-galactosidase precipitated
Φ 71-56-14	35	50	20	55
i^{q1} z^+ (+IPTG)	24	≦0.2	≦1	50

The fusion 71–56–14 was crossed on the phage $\lambda 80c_{1857}dlacS_7$ (Φ71–56–14) to increase the yield of *lac* product after heat induction of a bacterial strain lysogenic for the phage[2]. As comparison, strain $i^{q1}z^+$ grown in the presence of inducer IPTG was used. The heat induction of the fusion strain was carried out as in ref. 2. 0.2 ml of extract were mixed with 0.2 ml of antiserum. The mixture was left overnight at 4° C. The visible precipitates were centrifuged for one minute in an Eppendorf microcentrifuge. The supernatants were discarded. The precipitates were resuspended in 1 ml of TMS buffer[7] and spun again. The washing procedure was repeated twice. Then repressor and β-galactosidase activity were determined[7,8]. The values obtained were expressed as percentages of the activities found before precipitation with antiserum.

Table 2 Purification of repressor-galactosidase from strain i^{q1} (71-56-14)

Fraction	Total volume (ml)	Total Protein (mg)	*lac* repressor activity: Specific activity (% mg^{-1} ml)	Recovery (%)	Purification	β-galactosidase activity: Specific activity (Units mg^{-1})	Recovery (%)	Purification
Crude extract	2,200	40,500	4.4	100	1	3,180	100	1
Dialysed ammonium sulphate precipitate (0-35%)	330	5,700	32	100	7	21,600	96	7
Phosphocellulose (main peak)	260	333	146	27	33	29,900	8	9
Sepharose 6B	84	118	266	17	60	98,000	9	31

400 g of frozen cells were suspended in 600 ml of TMS buffer[7] and disrupted in a Gaulin homogeniser at 600 kp/cm^2. The precipitate of a 0–35% ammonium sulphate cut was dissolved in 0.011 M PC buffer (potassium phosphate *p*H 7.27, 0.5 mM dithioerithrol, 5% glycerol) and dialysed against the same buffer. The dialysed sample was applied to a 500 ml phosphocellulose column (Whatman P 11) equilibrated with 0.011 M PC buffer. The protein was eluted with a linear gradient starting with 1.1 l 0.011 M PC buffer in the mixing chamber and 1.1 l 0.19 M PC buffer in the reservoir. After the gradient the column was first washed with 250 ml of the reservoir buffer, then with 1 l of 0.24 M PC buffer. The main portion of repressor-galactosidase was eluted at a concentration of 0.11 to 0.13 M potassium phosphate. The pooled material from the main peak was concentrated by ammonium sulphate and then passed through Sepharose 6B (column 2.5 × 100 cm) equilibrated with 0.11 M PC buffer. The protein is eluted in a single peak, containing both *lac* repressor and β-galactosidase activities. The specific *lac* repressor activity of the pure protein was 266: this almost reaches the specific activity of pure *lac* repressor (1,500), if the fourfold increase of subunit molecular weight is taken into consideration.

the C terminus of *lac* repressor is dispensible for activity. Furthermore *lac* repressor functions even with β-galactosidase pinned to its tail.

Both *lac* repressor and β-galactosidase are tetramers. How does the fused protein aggregate? To determine its state of aggregation we analysed the pure material obtained from the sepharose step on a glycerol gradient. Both β-galactosidase and *lac* repressor activity sediment together at the position of normal β-galactosidase (S 16). We also analysed some of the minor fractions from the phosphocellulose column and found them to contain several species of faster sedimenting material. All fractions bind *lac* operator *in vitro*, but only the S 16 fraction binds operator DNA like normal *lac* repressor (Fig. 3).The plot shows that the DNA was 20% active. From the molar ratios of the protein and DNA we calculate that 20% of the protein is active in DNA binding. The higher aggregates seem also to bind, in a way not understood, to DNA pieces which do not contain *lac* operator.

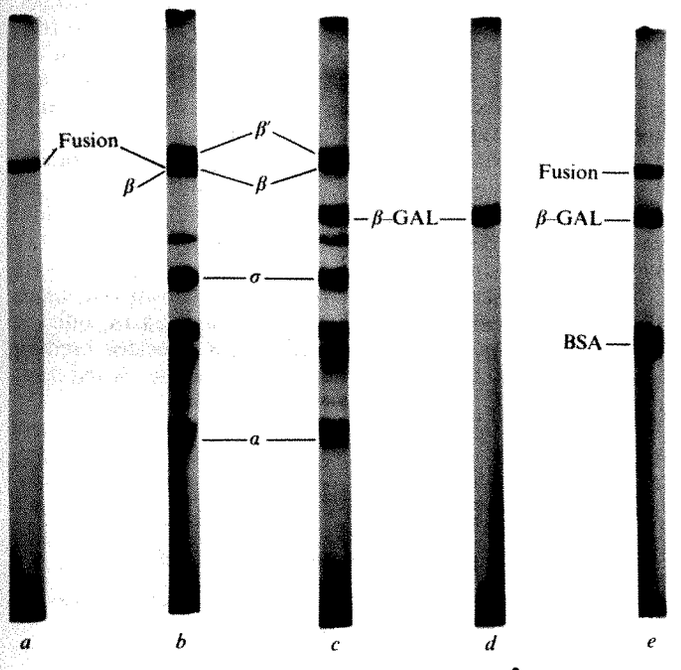

Fig. 2 Determination of the subunit molecular weight of repressor-galactosidase (fusion) by the SDS-polyacrylamide gel electrophoresis. 10 cm 5% acrylamide gels containing 0.1% SDS were prepared according to Weber and Osborn[13]. *a*, Repressor-galactosidase; *b*, repressor-galactosidase and *E. coli* RNA-polymerase (Miles-Seravac); *c*, RNA-polymerase and β-galactosidase; *d*, β-galactosidase; *e*, repressor-galactosidase, β-galactosidase, and bovine serum albumin.

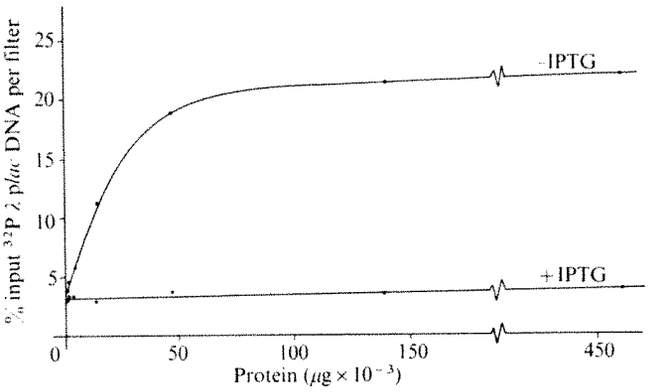

Fig. 3 Bound ^{32}P–λ*plac* DNA as a function of the amount of pure repressor-galactosidase in the assay. 3 ml of binding buffer (BB)[14] (without dimethyl sulphoxide), containing the protein, was divided into equal parts and 20 μl of a 0.1 M IPTG stock was added to one half. Then 0.1 ml of a ^{32}P–λ*plac* DNA solution was added and incubated for 8 min at room temperature. The constant amount of DNA in the 1.6 ml assay is 0.43 μg, with the activity of 23,000 c.p.m. per μg DNA. Each filter (Sartorius, 0.45 μm, 25 mm) received 0.5 ml, containing a total input of 3,000 c.p.m. The filters are washed with 1 ml BB each and counted in 10 ml Bray's Solution[15].

Finally, we analysed whether homology between *lac* repressor and the N terminus of β-galactosidase is responsible for the relative high frequency of the *i z* fusions. To test this we measured the frequency of *i z* fusions in a *Rec A* strain in which recombination is greatly reduced. We found the same number of fusions as in wild type. This excludes sequence homology. Sequence analysis which we have begun should define the unnecessary parts of β-galactosidase and *lac* repressor.

We thank Dr Kurz for β-galactosidase, Mr A. Schmitz for ^{32}P-labelled *plac* DNA and SFB 74 for support.

Mutagenicity of amino acid analogues in eukaryotes

A LOSS of fidelity in DNA replication and repair enzymes in both pro and eukaryotes, is often expressed as a mutation. Examples of this are shown in the mutator gene activity of a DNA polymerase mutant of T4 (ref. 1) and mutants with increased ultraviolet sensitivity or decreased recombination[2–4]. Springgate and Loeb[5] have reported the altered fidelity of the DNA polymerase of acute lymphatic leukaemia cells.

Amino acid analogue incorporation into protein has a varying effect on enzyme stability and activity[6–9] and it seems that the position of the amino acid in the polypeptide is the crucial factor[10].

We have recently reported[11,12] that the analogues *p*-fluorophenylalanine (PFP) and ethionine (ETH) are strongly mutagenic to reverse mutations in the basidiomycete *Coprinus lagopus*, inducing single base changes with a maximum of a 500-fold increase over the spontaneous mutation frequency shown by 2.5×10^{-4} M DL-PFP which induces 64% growth inhibition. PFP is mutagenic by incorporation into protein, while ETH mutagenesis is a function of transethylation of nucleic acids[12]. The mutagenicity of a number of amino acid analogues has been reported in *Chlamydamonas eugametos*[13] and in *Ustilago maydis*[14].

To gain a better understanding of the mutagenicity of amino acid analgues and because of the availability of defined replication and repair mutants in *Escherichia coli*, we tested the mutagenicity of PFP on reverse mutations in the bacterial system. Two point mutations were studied, the leucine requirement in strain C600 and the tryptophan requirement in strain A58. As with *Coprinus*, PFP was incorporated into the growth medium, in this case liquid Davis minimal medium, at concentrations ranging from 10^{-5} M DL-PFP to 5×10^{-4} M DL-PFP, a concentration which gave linear growth. At time zero, flasks were inoculated with exponentially growing cells and grown to stationary phase or for 5 h in the case of high analogue concentrations. The cells were washed and plated onto minimal medium reversion plates and viability plates supplemented with the auxotrophic requirement. In both cases, however, the analogue PFP had no effect on the reversion frequency of either the *leu* or *tryp* loci. The incorporation of ^{14}C-PFP confirmed that PFP was being incorporated into the protein fraction. Similarly, 10^{-3} M DL-PFP had no mutagenic effect on the reversion frequency of *Pseudomonas aeruginosa* PAO 381 (*leu*$^-$).

The mutagenicity of PFP was then tested on bacteriophage T4, chosen for its independent DNA polymerase synthesis. The effect of PFP on the plaque-forming ability of T4rII 271 on *E. coli* K and the plaque-forming ability of the amber mutant T4*am*122 on the nonsuppressive strain *E.coli* B/r/t$^-$, was studied. In both cases phage was inoculated at time zero into a permissive host grown previously for 2 h in the presence of 10^{-4} M DL-PFP. After a further 3 h, growth was stopped and the plaque-forming ability assayed. PFP had no mutagenic effect on either system.

Analogues norleucine and canavanine showed similar negative effects on *E. coli* reversion frequencies. The mutagenicity of ETH was not tested as the strains studied showed resistance to the analogue and ETH is not activated to S-adenosyl-ethionine in *E. coli* (ref. 15).

In *Coprinus*, PFP treatment followed by a 6 min dose from a 6 W Philips TUV mercury vapour lamp (8.54 erg cm^{-2}), showed a maximum mutational synergism of 9.6 times over the expected additive reversion frequencies (P. J. T., and D. L., unpublished). Mutational synergism is indicative of an interaction between mutational pathways; we have interpreted these results as the effect of PFP incorporation into ultraviolet repair enzymes. As PFP showed no mutagenicity in *E. coli* it might be possible to detect its effect by looking for mutational synergism between PFP and ultraviolet treatments; 5×10^{-5} M DL-PFP was chosen as a suitable concentration for pre-ultraviolet treatment, so as not to induce starvation-induced resistance enhancement[16]. Log phase cells of *E. coli* C600, grown in the presence of the analogue for 3 h, were irradiated for varying times. Analogue treatment did not affect ultraviolet survival or reversion frequencies of the *leu* locus.

To clarify the difference between pro and eukaryotic responses to analogue mutagenesis, we chose, as a system of comparison, mutations in the mitochondrial and nuclear genes of *Saccharomyces cerevisiae*. The existence of an independent mitochondrial DNA polymerase[17], the selective depression of mitochondrial protein synthesis in the presence of a fermentable substrate, and the differential sensitivity of certain strains to analogues in conditions of growth on nonfermentable or fermentable substrates[18], make the system advantageous for this study.

Two strains of *S. cerevisiae*, D26 (adenine requiring, erythromycin sensitive) and D6 (methionine requiring, erythromycin sensitive) were chosen. D26 showed a three-fold and D6 a two-fold increased sensitivity to PFP on nonfermentable substrate. The effect of PFP on the nuclear markers *ad* and *met* and mutation to erythromycin (1 mg ml^{-1}) resistance—the mitochondrial marker—were studied. Liquid glucose yeast extract and glycerol yeast extract media, supplemented with the analogue at concentrations giving up to 50% growth inhibition were inoculated with 10^6 yeast cells and grown to stationary phase. The cells were washed twice and tested on Wickerams synthetic medium, fully supplemented in the case of viability plates, but without the auxotrophic requirement in the reversion plates. Resistance to erythromycin was tested on glycerol yeast extract with 1 mg ml^{-1} erythromycin added (Table 1).

The positive effect of the analogue on the nuclear genes in yeast, confirms the results in *Coprinus*. The entirely negative effect of the analogue on mitochondrial mutation, if we can

Table 1 The mutagenic effect of PFP on mitochondrial and nuclear markers in *Saccharomyces cerevisiae* strains D26 (*ad*$^-$ *eryth*^{s}) and D6 (*met*$^-$ *eryth*^{s}) when supplemented to both yeast extract glucose (YES) and yeast extract glycerol (YEG) media

		Mutation frequency per 10^6 viable cells			
		Control	1.5×10^{-3} MPFP	3.0×10^{-3} MPFP	4.5×10^{-3} MPFP
		YEG and YES	YEG	YES	YES
D26	*ad*$^-$	3.5	3.3	9.2	23.2
	eryth^s	24.6	25.8	13.5	17.6
D6	*met*$^-$	3.0	5.9	76	—
	eryth^s	24.3	10.4	13.1	—

compare the mitochondrial chromosome with the chromosome of prokaryotes, confirms the negative results in prokaryotes.

It might be possible to explain the differential response to PFP on the basis of amino acid composition of DNA replication and repair enzymes in pro and eukaryotes, that is, while phenylalanine might be strategically placed in fungal replication and repair enzymes, such as at the active site, phenylalanine differently placed in bacterial and mitochondrial replication and repair enzymes, could account for the difference. From Table 1, the maximum mutagenic effect obtained in yeast is considerably lower than in *Coprinus*, at comparable growth inhibitory concentrations. This can also be explained on the differential importance of phenylalanine in the active centres in the DNA replication and repair enzymes in yeast and *Coprinus*. If this is so, then certain analogues should show mutagenicity in prokaryotes. The few we tested did not. Pardee and Prestide[19] reported that no mutagenic action of 7-azatryptophan was noted in mutation to streptomycin resistance in *E. coli* or the plaque-forming ability of T2.

The differential response might implicate the presence of histone and nonhistone proteins in eukaryotic chromosomes. PFP induces haploidisation inversions and transversions in certain fungal species by affecting chromosomal division[20] and integrity[21]. In *Chlamydamonas* the phenylalanine analogue 2-amino-3-phenylbutanoic acid, as well as being mutagenic, causes chromosomal abberations, suggested by McBride and Gowan[13] to be the result of incorporation of the analogue into chromosomal associated proteins. Hare[22] reported that canavanine incorporation into histone and nonhistone proteins in mice, mammalian and hamster tumour cells, inhibited DNA synthesis. Chromosomal abberations and an exaggerated response to mutagens have been found in children suffering from severe protein starvation[23].

Several reports have been made of the differential response of bacteria and higher organisms to various mutagens[24-27]. Most of these effects have been attributed to physiological differences between pro and eukaryotes. The differential response to amino acid analogues indicates a difference on the basis of the replication and repair of DNA.

We thank Dr B. A. Bridges for pointing out to us the work of George and Witkin[28] suggesting that some ultraviolet repair enzymes might be inducible by ultraviolet. If this is true then the interpretation of our experiments with PFP and ultraviolet light is more uncertain. This does not, however, alter the validity of the comparison between *C. lagopus* and *E. coli*.

We thank the Wellcome Trust for supporting this research, submitted as part of a PhD thesis to the University of London. *E. coli* strain C600 was supplied by Dr R. Rowberry; strain A58 by Dr S. Neale; *Ps. aeruginosa* strain PAO 381 by Dr P. Clark and *S. cerevisiae* strains D26 and D6 by Dr D. Wilkie.

Naturally occurring cytotoxic anti-tumour antibodies in sera of congenitally athymic (nude) mice

IT has been suggested that a natural function of the immune system is the detection and elimination of nascent autochthonous tumours and that clinical tumour development reflects a failure of this immune surveillance function[1]. Evidence for the involvement of thymus dependent immune processes in the prevention of spontaneous malignant disease is lacking. Thus, no significant increase in tumour incidence has been observed in either neonatally thymectomised (R. T. Prehn, personal communication) or congenitally athymic (nude) mice[2,3]. If, as suggested by other studies, immune surveillance does, in fact, operate[4], it is likely that it will involve a thymus-independent immune process. We have detected in sera of many normal mice IgM antibodies which are cytotoxic for several spontaneous and induced tumour cell lines (unpublished). The possible role of these antibodies in immune surveillance is uncertain, but if they are a manifestation of active immune surveillance, they would be expected also to occur in the sera of nude mice.

Nude mice (from Olac Ltd, Southern Bicester, England) have been studied in this laboratory and shown to have a near complete absence of θ-positive thymus-derived lymphoid cells[5]. Sera were obtained from these mice and were stored in aliquots at $-20°C$. The sera were tested for complement dependent cytotoxic activity against several tumour lines maintained in this laboratory. Two tumours which recently arose spontaneously in normal C3H mice were included in this study. One is a lymphosarcoma with surface bound IgG_2 immunoglobulin and is referred to as γG2LS. The other is an *in vitro* cell line derived from an ovarian teratoma. The cells are relatively undifferentiated epitheloid cells and are designated Ter-B. The other tumours tested are maintained in ascites form and are used extensively in several laboratories. They are C1300, a neuroblastoma of strain A mice; and EL-4, L1210, and PU-5, leukaemias of C57BL, DBA/2, and BALB/c mice, respectively.

Individual sera obtained from six, ten-week-old nude mice were tested undiluted against various tumour cell lines and were found to possess significant complement dependent lytic activity against all but the PU-5 target cells. A pool of the sera from the individual nude mice was also tested at several dilutions against the different tumour cell lines. The results of these cytotoxic assays are depicted in Fig. 1. The observed levels of cytotoxic activity are within the range of variation obtained when different sera of normal mice are similarly tested (unpublished). Sera from nude mice show no cytotoxic activity when tested on normal allogeneic spleen cells.

The presence of naturally occurring cytotoxic antibody in the sera of nude mice indicates the capacity of the thymus-independent immune system to respond immunologically to

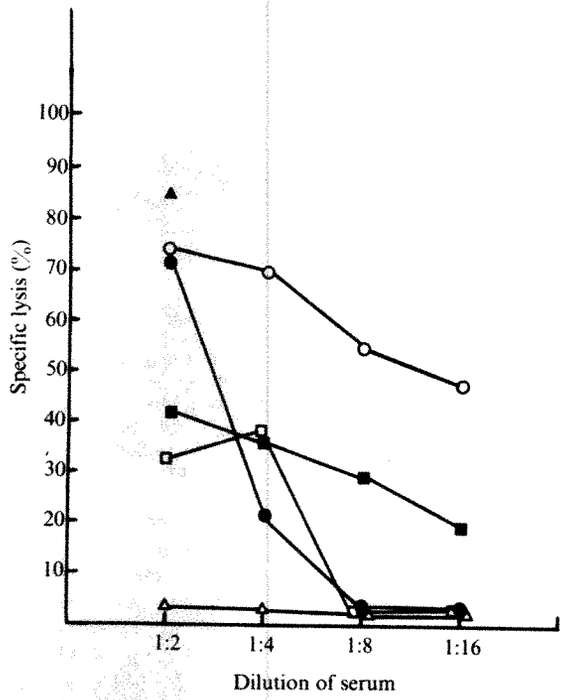

Fig. 1 Complement dependent antitumour cytotoxic activity of serum obtained from nude mice. Target cells were obtained from the following tumours: Ter-B (▲); γG2LS (○); L1210(●); C1300 (■); E1–4 (□), and PU–5 (△). See text for description of tumours. In each assay, 50 μl of a suspension containing 3×10^6 tumour cells ml^{-1} in Dulbecco's modified minimal essential medium with 10% foetal calf serum were added to 50 μl of a dilution of pooled serum obtained from nude mice. The mixture was incubated for 45 min in a humidified incubator at 37° C with a 10% CO_2:90% air atmosphere. The cells were washed with 300 μl of medium and resuspended in 50 μl of a 1:6 dilution of rabbit serum as a source of complement. The rabbit serum had been previously absorbed at 2° C with a one-fifth volume of mouse spleen cells to reduce its toxicity. After 45 min incubation in the presence of complement, the tubes were placed in an ice bath. A volume of 50 μl of trypan blue solution was added to the cell suspensions and aliquots removed for microscopic enumeration of % nonviable (stained) cells. Two groups of controls were included in each experiment: first, incubation of tumour cells with serum of nude mice, but followed by the addition of medium rather than complement and second, initial incubation of the cells in medium followed by incubation in complement. Less than 5% nonviable cells were observed with the first group of controls for each tumour cell line tested. Less than 15% nonviable cells were observed with the complement control (C) for each of the tumour cell lines tested. Specific lysis was calculated by subtracting C from the % nonviable cells observed with serum plus complement, dividing by (100–C) and multiplying by 100. Duplicate determinations of cytotoxic activity of nude mouse sera were made for each tumour cell line.

tumour-associated antigens. The nature of the antigens recognised by naturally occuring antibodies in sera of normal mice is currently being investigated. Some of these antigens are expressed in appreciable amounts during foetal development, while others are expressed in certain allogeneic strains[6,7]. It is possible that cytotoxic anti-tumour antibody production is partly maintained in normal and nude mice by the derepression of these foetal and alloantigenic components on nascent autochethonous tumours.

Homology between human breast tumour RNA and mouse mammary tumour virus genome

Several studies have provided indirect evidence linking particles related to mouse mammary tumour virus (MuMTV) with human breast cancer[1–3]. In addition to morphological and biochemical similarities between human milk particles and known oncornaviruses shown in several laboratories[4], Axel *et al.*[5] demonstrated partial homology between MuMTV genome and polysomal RNA isolated from human breast tumour by molecular hybridisation experiments. Using Cs_2SO_4 density gradient analysis they showed that 67% out of 29 tumours tested had detectable amounts of MuMTV-related RNA. But because of intrinsic problems involved in Cs_2SO_4 gradient analysis it is not possible to determine hybridisation quantitatively. In this paper we describe hybridisation experiments using MuMTV-specific DNA probes and human tumour RNA under stringent conditions.

We have used single-strand specific nuclease (S_1) from *Aspergillus oryzae*[6] for the detection of hybrid formation. This enzyme specifically degrades single-stranded nucleic acids but not double stranded nucleic acids or DNA–RNA hybrids. Highly radioactive, complementary and predominantly single-stranded DNA synthesised by endogenous RNA-directed DNA polymerase of MuMTV in the presence of actinomycin D was used as a probe to detect MuMTV-related sequences in whole cell RNA isolated from human tumours. Most of the human lesions were carefully selected by examining representative frozen sections histologically to give maximum ratio of malignant cells to stromal cells. Detailed data on the histopathology and antigenicity of the tumour tissues in relation to hybridisation will be published elsewhere.

Optimum hybridisation conditions described by Varmus *et al.*[7] were used (see Table 1 for details). The experiments were performed under conditions of excess RNA and limiting DNA probes. Under these conditions the rate of hybridisation is determined by the concentration of homologous RNA and time of incubation. The product of RNA (mol l^{-1}) and time of incubation (s) is designated C_rt which is similar to the C_0t value described by Britten and Kohne[8]. The C_rt values were computed from the A_{260} of the RNA samples[8] and corrected to 0.18 M[Na^+] according to Britten and Smith[9].

To provide a rapid determination of hybridisation, tumour RNAs were incubated with MuMTV DNA probe at C_rt values greater than 10^4. Table 1 summarises the results obtained. Any tumour RNA that hybridised more than 10% of the DNA probe was considered significantly positive. It can be seen that out of 17 tumours tested 5 had RNA sequences homologous to MuMTV genome. In one case (HuT 11) the tumour tissue itself revealed some homologous RNA but surrounding 'control' tissue was negative for MuMTV-related RNA sequences. When the DNA probe synthesised by Mason-Pfizer monkey virus

RNA from tissues was isolated by SDS-phenol extractions, DNase treatment and ethanol precipitation as described by Varmus *et al.*[7] and resuspended in 0.02M Tris HCl *p*H 7.2 to give a concentration of about 10 mg ml^{-1}. The DNA probes were synthesised from ~1.5 mg purified MuMTV from RIII mouse milk. The following solutions were added to the virus suspended in 200 μl 0.01 M Tris HCl *p*H 8.3: 24 μl of 1 M DTT; 20 μl of 1% bovine serum albumin; 12 μl of 5% Nonidet–P40; 16 μl of 2.5 mM ATP; 50 μl of 1 mg ml^{-1} actinomycin D; 100 μl of a mixture containing 0.25 M Tris–HCl *p*H 8.3, 0.05 M NaCl, 0.04 M $MgCl_2$; 60 μl of a mixture containing 0.01 M each of dCTP, dATP and dGTP; and ^{3}H–TTP (specific activity 50 Ci mmol^{-1}) was added to give a concentration of 10 μM. After the incubation at 37° C for 18 h the reaction was stopped by adding 1/10 volumes of 10% SDS and 4M NaCl. The reaction mixture was diluted to 2 ml with a buffer containing 0.01 M Tris HCl *p*H 8.3, 0.01 M EDTA and 0.1 M NaCl and extracted three times with phenol-cresol (7:1 *p*H 7.5). Following overnight ethanol precipitation the template RNA molecules were digested by treating the probes in 0.003 M EDTA with 100 μg ml^{-1} RNase A at 37° C for 1 h. The RNase was destroyed by the treatment with 0.6 M NaOH at 37° C for 1 h (ref. 12). After neutralisation with HCl the probes were precipitated in ethanol and resuspended in 0.02 M Tris HCl *p*H 7.2 The hybridisation reactions were carried out at high C_rt values (see text) in duplicate 5 μl mixture sealed in capillary tubes and incubated at 68° C for 66 h. The mixture contained 30 to 50 μg RNA and 300–500 c.p.m. of DNA probe in 0.04 M Tris *p*H 7.2 0.002 M EDTA and 0.6 M NaCl. After the incubation hybridisation mixture was treated with single-strand specific nuclease (S_1) from *Aspergillus oryzae*[6] according to the method described by Varmus *et al.*[7]. The probes annealed with heterologous RNA (rat liver) were also treated with S_1 to give self-hybridisation values which were used to correct the results.

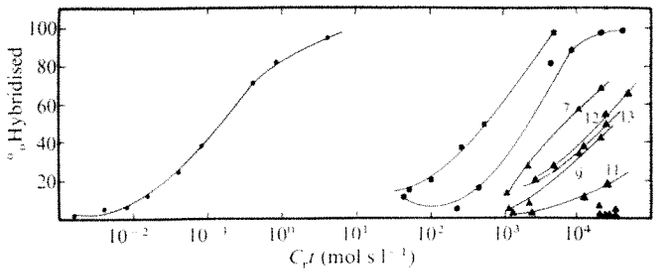

Fig. 1 C_rt curve analyses of hybridisation between MuMTV DNA probes and RNAs from various sources. The conditions of hybridisation were the same as in Table 1. Different C_rt values were obtained by diluting the test RNAs with heterologous (rat liver) RNA. ●, MuMTV 70S RNA; ■, RIII lactating mammary glands; ♦, C57 transplanted mammary tumour; ▲, various human tumours including positive tumours (Table 1) HuT 7, 9, 11, 12 and 13.

(MPMV, a virus isolated from the breast tumour of a rhesus monkey) was used for hybridisation under the same conditions, none of the tumours tested showed any RNA sequences homologous to MPMV genome (data not shown).

Hybridisation kinetics for the positive tumour RNAs were observed by C_rt curve analysis shown in Fig 1. For comparison, C_rt curves obtained with MuMTV 70S RNA, RNA from RIII lactating mammary glands and from C57 transplanted mammary tumours are also illustrated. All five positive human tumour RNAs showed varied rates of hybridisation. By comparing $C_rt_{1/2}$ values of various human tumour RNAs with MuMTV 70S RNA it is possible to arrive at an estimation of virus-related RNA molecules in these tumours. As seen in Table 2, the numbers of MuMTV related RNA molecules per cell in these tumours was low ranging from 1.5 to 8. These estimates are based on the hybridisation of a nonuniformly represented DNA probe and are likely to vary depending upon the representation of viral genome in the synthesised DNA probes.

Thermal stability of hybrids is an important criterion for establishing their true nature. Figure 2 shows a thermal stability experiment performed on the hybrids formed between MuMTV DNA and human tumour RNA. The T_m for the hybrids of MuMTV DNA and RNA from RIII lactating mammary gland (a tissue which produces MuMTV) was 69° C compared with 62° C for the hybrid of MuMTV DNA and human tumour RNA. This difference in thermal stability would indicate about 5% mismatching between the MuMTV DNA and the tumour RNA (ref. 10). Considering the species differences between the sources of two nucleic acids, the hybrids were remarkably well matched.

Extensive electron microscopic searches have failed to reveal unequivocally the presence of complete MuMTV-like

Table 2 Estimations of MuMTV 70S RNA equivalents per cell

Sample	$C_rt_{1/2}$*	% Viral RNA	MuMTV 70S RNA equivalents per cell
MuMTV 70S RNA	1.5×10^{-1}	100	—
HuT 7	7.5×10^3	0.002	8
HuT 9	3.3×10^4	0.00045	1.5
HuT 12	2.1×10^4	0.00072	2.2
HuT 13	2.75×10^4	0.00054	1.68
RIII lactating mammary glands	5.2×10^2	0.029	90
C57 transplanted mammary tumour	1.9×10^3	0.0078	25

*C_rt at which 50% of the input DNA probe was hybridised
By comparing $C_rt_{1/2}$ of MuMTV 70S RNA and of the test RNAs, percentage of MuMTV-related RNA in a given sample was determined. Based on assumptions that each MuMTV 70S RNA weighs 1.6×10^{-11} μg and total cellular RNA weighs 5×10^{-6} μg, the number of MuMTV 70S-related RNA molecules per cell was estimated.

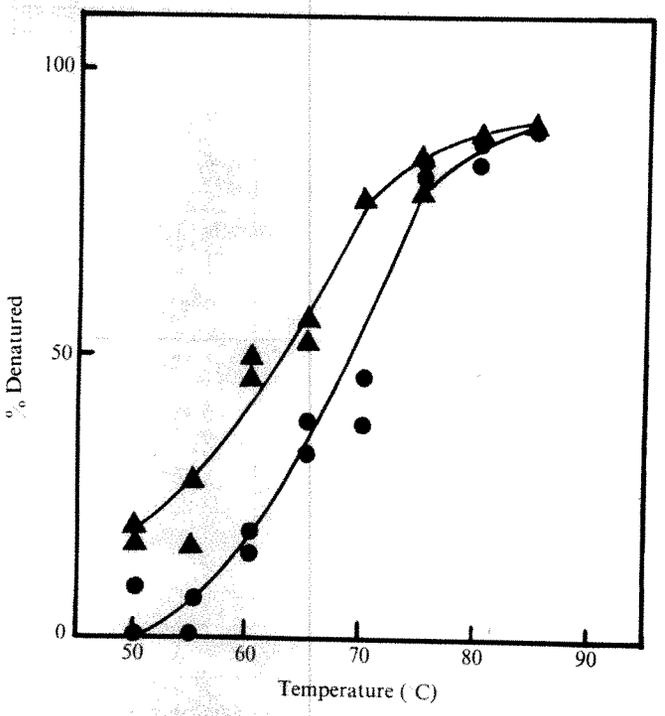

Fig. 2 Thermal stability experiment. Approximately 7,000 c.p.m. of MuMTV probe DNA were annealed with RNAs from human breast tumour (▲) and RIII lactating mammary gland (●). Following ethanol precipitation the hybrids were resuspended in 0.01 M Tris HCl *p*H 8.3 and aliquots were heated at various temperatures for 15 min, chilled quickly and treated with S_1 nuclease as described in Table 1.

particles in human breast tumours. (A. B. V., unpublished work, and N. H. Sarkar, personal communication.) But the results shown in this communication are very similar to those reported[7] for murine tissues apparently negative for MuMTV production. Particularly, in spontaneous mammary tumours of BALB/c mice, B-particles of MuMTV are not seen (N. H. Sarkar, personal communication), but a small amount of MuMTV-related RNA is present[7,11].

According to current theories of viral oncogenesis, the genome of the virus should be integrated with the host genome. If a MuMTV-related virus is involved in the aetiology of human breast cancer, one should expect MuMTV-related genomic information integrated into the DNA of the tumour cells. We plan to investigate this possibility using molecular hybridisation techniques.

We thank Drs Harold Varmus and J. Michael Bishop for discussion and a gift of S_1 nuclease. We also thank G. S. Fout and G. Heubel for technical assistance. This work was supported by grants and a contract from the US National Cancer Institute and the State of New Jersey.

Levamisole inactive in treatment of four animal tumours

LEVAMISOLE (2,3,5,6-tetrahydro-6-phenylimidazo (2, 1-b) thiazole) a compound known to be active against a wide range of nematodes[1,2], has been reported to enhance the humoral and cellular immune responses of animals and to reduce the incidence of both primary tumours and lung metastases in the Lewis lung (3a) tumour system in C57BL mice[3]. We report here studies on the effect of levamisole on the growth of four transplantable tumours, all known to be immunogenic. They were: a transplantable adenovirus 12-induced tumour of CBA mice[4]; a chick embryo lethal orphan (CELO) virus-induced tumour of hamsters[5]; a Moloney leukaemia virus-induced lymphoma of BALB/c mice[6]; and a chemically-induced metastasising anaplastic neoplasm of inbred rats[7]. We also studied the effect of levamisole on the humoral antibody response to influenza virus vaccine in hamsters.

The tumours were maintained by serial, subcutaneous inoculation of tumour fragments at 2–3 week intervals. For inoculation of experimental animals, small tumours of 10–15 mm diameter were removed from the animals, freed from normal and necrotic tissue and washed with Hank's saline. They were then minced to small fragments and treated with 0.25% trypsin; the resulting single cell suspension was washed three times in Hank's saline, and suspended to the required concentration in Eagle's minimal essential medium containing 2% inactivated calf serum. The cells were used immediately to inoculate animals. A 10 mg ml^{-1} solution of levamisole was made in pyrogen-free saline, and stored at −20°C. Immediately before use, aliquots of the stock solution were thawed, and diluted to the required concentration in pyrogen-free saline.

Hamsters were inoculated subcutaneously with 5×10^6 viable adenovirus 12-induced tumour cells in an 0.2 ml volume. One group of these animals was inoculated subcutaneously with 0.5 mg kg^{-1} of levamisole from 4 d before inoculation with tumour cells, a second group was inoculated with levamisole from the day of tumour cell inoculation, and a third group was untreated. Levamisole was given every 48 h from the start of treatment to the end of the study. The hamsters were examined regularly for tumours, and the diameter of tumours were measured with calipers. The results are shown in Table 1. Of the 10 hamsters which were not treated with levamisole, a single tumour was observed 17 d after inoculation, and three animals had large tumours (> 2.5 cm in diameter) 35 d after inoculation. In contrast, the incidence of tumours for hamsters which had been treated with levamisole from 4 d before tumour

cell inoculation was 7/10, and for animals inoculated with the drug from the day of tumour cell inoculation the incidence was 9/10, 35 d after inoculation. The incidence of tumours in the two groups of hamsters treated with levamisole, when taken together, was significantly greater than that for the untreated animals ($\kappa^2 = 4.965$; $N = 1$; $P = <0.02$). Levamisole treatment therefore increased the incidence of transplanted adenovirus 12-induced tumours in hamsters.

In a similar way, the transplantability of a CELO virus-induced tumour of hamsters and a Moloney virus-induced lymphoma of BALB/c mice was investigated in animals treated with levamisole. The incidence of both these tumours was similar in treated and untreated animals. Thus, levamisole treatment did not decrease either tumour incidence or the size of tumours produced by transplanted CELO virus-induced tumour cells of hamsters, or Moloney virus-induced tumour cells of mice.

Groups of rats were inoculated into the foot pad with 5×10^6 RD3 cells; some of these animals were given levamisole (0.5 mg kg^{-1}) daily for 5 d before tumour cell inoculation, others from the day of tumour cell inoculation, and a further group were given levamisole from 14 d after tumour cell inoculation when the tumours were well established. The incidence of tumours at the site of inoculation, and the grade of metastatic tumour growth, is shown in Table 2. For animals treated with levamisole before or from the day of, tumour inoculation, the incidence of tumours in the foot pad and the extent of metastatic tumour growth in the popliteal or para-aortic lymph glands was similar for treated and untreated control rats (Table 2, Experiments 1 and 2). In the remaining test, where levamisole treatment was started 14 d after tumour cell inoculation, the degree of metastatic spread was less than that of untreated rats (Table 2; Experiment 3). This result, however, could not be repeated in further studies. The results indicate that levamisole did not significantly affect the incidence of primary or metastatic growth of RD3 tumour cells.

Two groups of hamsters were infected intranasally with influenza virus A1/FM/1/47 (H1N1). It has been shown in previous studies that hamsters do not produce haemagglutination inhibiting (HI) antibody in response to conventional doses of influenza virus A2/Aichi/68 vaccine unless previously infected with live influenza A virus[8,9]. Three weeks after virus infection, these hamsters, which all developed HI antibody to the infecting virus, together with two groups of normal hamsters, were inoculated intramuscularly with 150 CCA of inactivated influenza virus A2/Aichi/2/68 vaccine. One group of infected and one group of uninfected animals were also given 0.1 mg kg^{-1} levamisole subcutaneously on the day of immunisation, and subsequently every 48 h for 14 d. Serum specimens were collected from all hamsters at each stage of the experiment from the retro-orbital sinus, and tested for HI antibody. The results are shown in Table 3. None of the hamsters given vaccine only produced demonstrable serum HI antibody and one of the immunised animals given levamisole produced antibody (Table 3). For hamsters infected with influenza virus A1/FM/1/47 and later immunised, one animal

developed serum HI antibody detectable at 14 d after inoculation, and four developed antibody after 21 d. In contrast, for the six virus infected and immunised hamsters which were given levamisole, four developed serum HI antibody to the vaccine virus at 14 d after immunisation (geometric mean titre (GMT) 1:22.8) and one developed HI antibody at 21 d after immunisation (GMT = 1:34.6). Thus, in hamsters primed by previous infection with influenza virus A1/FM/1/47, levamisole promoted an earlier serum HI antibody response, and higher titres of antibody were detected.

The reaction of the host to experimental chemical or virus-induced tumours has been shown to be a cell-mediated immune reaction[10,11] and this cellular immune reaction has been specifically shown for the adenovirus 12-induced tumour of CBA mice and CELO virus-induced tumours of hamsters used in the present study (ref. 12 and R.C.R., and C.W.P., unpublished). In addition, factors which promote the cellular immune reaction of the host may result in an increased immunity to transplanted tumour cells[13-15]. Levamisole has been reported to increase the immune response of mice; the drug re-established the immune reactions of aged mice, and enhanced cell-mediated immune reaction. In addition, levamisole was reported to cause a significant reduction in primary tumour formation and metastases in mice inoculated with a transplantable lung tumour[3]. In our study, however, the effect of the drug on tumour development could not be extended to four further transplanted animal tumours. Levamisole, at the same concentration as used in the earlier study, had no effect on three transplantable tumours; and the effect on an adenovirus 12-induced tumour of CBA mice was to enhance tumour development.

Sera from CBA mice bearing transplanted adenovirus 12-induced tumours has been shown to contain a serum factor which promoted the development of transplanted tumours by interfering with cell-mediated immunity[12]. Blocking factor has been described for other tumour-bearing animals[16,17] and in serum from patients with cancer. It has been suggested that the blocking factor is a serum antibody[18] or antigen-antibody complex[19]. Thus, the promotion of humoral antibody may lead to the formation of blocking factors which would enhance tumour growth.

Our study shows that levamisole enhanced the serum HI antibody response of hamsters to A2/Aichi/68 vaccine, and lack of activity to this drug may be due to the stimulation of humoral antibody and the blocking of cell-mediated immunity. In contrast, levamisole was shown to reduce the incidence of Lewis 3a tumours of mice[3]. The effect of levamisole may vary for different tumour systems, therefore, as the antigenicity of tumours and the immune response to different tumours is not identical.

Levamisole was supplied by Dr D. C. Davey, of ICI Ltd, Macclesfield, Cheshire.

Embryo-derived teratocarcinomas elicit splenomegaly in syngeneic host

MOUSE egg-cylinders transplanted to extrauterine sites develop either as teratomas (benign tumours composed of adult tissues) or as teratocarcinomas (retransplantable malignant tumours containing, in addition, undifferentiated embryonic carcinoma cells)[1-4]. Rat egg-cylinders similarly transplanted, however, always develop as teratoma[5]. When transplanted to a syngeneic host, C57BL mouse egg-cylinders develop as teratomas but when transplanted to (C3H × C57BL)F_1 hybrids they develop into teratocarcinoma[3,4]. This suggests that the host reaction is important in determining the fate of a transplanted embryo. Specific embryonic and foetal antigens which are re-expressed during malignant transformation are now well established[6-8], and we thought that an immunological reaction of the host against embryonic antigens in the egg-cylinder might determine whether the transplant develops as teratoma or teratocarcinoma. Splenomegaly is considered to be a sign that a host has reacted to the antigenic stimulation of a graft or tumour[9,10], and we have found that although it is always present in mice with transplanted egg-cylinders, it is much more pronounced in those with teratocarcinoma. Splenectomy, however, reduced the growth of the transplanted embryos, suggesting that the immunological reaction of the host stimulates the growth of the graft.

Seven-day-old mouse egg-cylinders (the day when the vaginal plug was found was considered day 0) were isolated from uterine swellings of pregnant C3H/H mice and transplanted under the kidney capsules or into the testes of 6-8-week-old syngeneic or (C57BL × C3H/H)F_1 hybrid recipients as before[1,2]. To exclude reaction to antigens linked to the Y chromosome[11], and presumably present in half of the transplanted egg-cylinders, all recipients were males. Animals were killed two months later. Tumours grown from the embryos and the spleen of each tumour-bearing animal were weighed and examined histologically. Male animals of the same age kept under identical conditions served as controls for the weight of the spleen. Some of the C3H/H animals were splenectomised at the time of grafting.

As Table 1 shows, the weight of the tumours obtained from under the kidney capsule differed significantly from those obtained by grafting the embryo into the testis. Tumours from embryos grafted to hybrid recipients weighed significantly more than those in syngeneic hosts. Tumours from embryos grafted into syngeneic hosts which were splenectomised at the time of transplantation were much smaller and weighed significantly less than tumours

Table 1 Weight of tumours grafted to the testis and under the kidney capsule

Location	Strain of recipient: C3H/H	(C3H/H × C57BL) F_1 hybrid	C3H/H splenectomised
Kidney	3,212 ± 689 (31)	4,130 ± 805 (29)	1,139 ± 449 (21)
Testis	2,149 ± 529 (39)	—	—

All tumours were obtained from grafts of 7-d-old C3H/H mouse egg-cylinders. Weight is given in mg ± s.e. When the *t*-test was applied, values for each group differed significantly from all others ($P < 0.01$). The number of animals in each group is given in parentheses.

in untreated syngeneic hosts, irrespective of the site of transplantation.

All grafts induced some increase in the weight of the host's spleen (Table 2). Embryo-derived teratoid tumours were classified on a histological basis into benign teratomas and teratocarcinomas. Spleens were significantly heavier in animals bearing teratocarcinomas than those bearing tertomas. Tumours obtained from under the kidney capsule induced significantly more splenomegaly than those in the testis. The difference in the weight of spleens is not only statistically significant when all tumours in the kidney are compared with tumours in the testes, but also when teratomas are compared with teratomas and teratocarcinomas are compared with teratocarcinomas in the two locations. In spite of the larger size of tumours obtained under the kidney capsule in hybrid hosts compared with those in syngeneic hosts (Table 1), there was no difference in the weight of spleens in the two groups (Table 2).

Table 2 Weight of spleens in mice bearing embryo-derived teratomas and teracarcinomas

Location	Strain of receipient: C3H/H		(C3H/H × C57BL) F_1 hybrid	
	Teratoma	Terato-carcinoma	Teratoma	Terato-carcinoma
Kidney	194 ± 30 (16)	374 ± 37 (15)	162 ± 37 (13)	353 ± 37 (16)
Testis	132 ± 3 (23)	276 ± 23 (16)	—	—
Control	117 ± 2.45 (18)		122 ± 3.22 (15)	

Values are given in mg ± s.e. The *t*-test was used to compare means. All values differed significantly from the controls ($P < 0.01$) as well as among themselves ($P < 0.01$) except for the weight of spleens in C3H/H and F_1 hybrid mice grafted with embryos under the kidney capsule. All tumours were derived from C3H/H egg-cylinders. The number of animals in each group is given in parentheses. Tumours containing undifferentiated embryonic cells (embryonic carcinoma cells) were classified as teratocarcinomas. Spleens from normal untreated males served as controls.

Our data indicate that the weight of the spleen increases in all animals bearing grafted embryos. This splenomegaly suggests an immune type of reaction. Recent results have shown a significant increase in the total number of spleen cells, the number of lymphoid subpopulations and in T and B cell functions in tumour-bearing animals[12]. Since only the largest grafts contained necrotic tissue, splenomegaly resulting from reaction to tissue destruction could be excluded with a high degree of certainty. Histologically, the appearance of these spleens corresponds to the descriptions of graft-induced splenomegaly[9,10].

We found heavier spleens in animals with teratocarcinomas than in those with small, nonproliferating teratomas (Table 2). There are at least two possible explanations for this: one is that there is more tissue for antigenic stimulation available in the large teratocarcinomas than in the usually much smaller teratomas; second, since teratocarcinomas contain foci of undifferentiated embryonic cells, these cells are developmentally and antigenically different from the host, and therefore may exert a stronger antigenic stimulation than the cells in the teratomas.

When transplanted, all grafts contain undifferentiated embryonic cells[13], but these disappear from teratomas and persist only in teratocarcinomas. We suggest that the slight increase in the weight of the spleen of the teratoma-bearing animal represents a reaction to the presence of undifferentiated embryonic cells during the first 15 d after grafting of the egg-cylinder. Only the persistence of embryonic undifferentiated cells in the teratocarcinomas, however, could induce a three-fold or even more pronounced increase in the weight of the host's spleen.

Whether the size of testicular tumours, which differs as Table 1 shows, is determined by some anatomical factor (blood supply, lower temperatures due to the scrotal location, or tenseness of the tunica albuginea) or is related to a possibly more or less immunologically privileged site for the growth of embryonic tissues remains to be determined.

The greater weight of tumours obtained in hybrids at the same site in syngeneic hosts may be explained by minor antigenic differences between host and graft which provoked a stimulatory immune reaction[14]. The reduction in weight of embryo-derived tumours caused by splenectomy at the time of grafting might be explained if blocking antibodies prevent tumour-invoked cell-mediated immunity in intact mice. In splenectomised animals such antibodies could be synthesised in much smaller quantities, leaving embryonic carcinoma cells exposed to the cellular immune response. Observations[8] that stimulation with foetal cells protects splenectomised hamsters much better than intact hamsters against SV40-induced tumours could be explained by similar mechanisms. Enhancing antibodies[15], secreted by the spleen, and thus not present in splenectomised animals, could also explain the smaller tumour growth. Our finding[3,4] that about half of the transplanted embryos develop as teratocarcinomas and half as teratomas might mean that small changes in the host's immune response could swing development either way. Tumour cells probably produce many different classes of antibody, so that the outcome of tumour-immune system interaction would depend on many functions not easily controlled during an experiment. We are now trying to characterise the humoral and cellular response elicited by embryo-derived tumour, and to discover how different components of immune response might regulate the development of transplanted embryo.

This work was supported by the Council for Scientific Affairs of SR Croatia and by the National Institutes of Health.

Immunisation of marmoset monkeys with a killed oncogenic herpesvirus

HERPESVIRUSES are suspected to be causal agents in human malignant neoplasia. At the present level of knowledge, clinical trials in man with viral vaccines against oncogenic herpesviruses cannot be initiated, but the oncogenic herpesviruses derived from monkeys[1,2] can be used *in vivo* to study the problems of herpesvirus cancer vaccines. The oncogenic herpesvirus saimiri (HVS) regularly induces malignant lymphoma in cotton topped (CT) marmoset monkeys (*S. oedipus*). A killed vaccine from HVS was developed in our laboratory and tested for safety and efficacy in this primate model system.

For the production of the killed vaccine HVS isolate No. 810 (ref. 1) was cultivated on owl monkey kidney (OMK) cells[3].

‡ Titres of HVS specific complement fixing antibodies.
§ Monkey still alive.
¶ Sera had anticomplementary activity.

Three days before collection, when the cytopathic effect of HVS appeared, the OMK cell cultures were washed and fed with fresh medium, free of serum. The stock virus, stored at 4° C, was centrifuged twice at 2,000*g* for 10 min and the clarified fluid containing virus was passed through Millipore membrane filters (450 μm). The filtrate was sonicated for 10 s (Branson Sonifier B-12, micro tip, maximal output). The infectivity titre of this preparation, measured in OMK cells, was $10^{5.0}$–$10^{5.5}$ $TCID_{50}$ ml^{-1}. The virus was distributed into 100 ml glass vials and heated at 56° C for 4 h. This heat-treatment completely destroyed the infectivity which was tested in OMK cell cultures. The heat inactivation did not significantly reduce the titre of the HVS specific complement fixing (CF) antigens. CF titres were determined according to standard techniques[4] using an HVS antiserum from an owl monkey[3]. In addition to the heat treatment the virus preparation was incubated with formaldehyde (100 μg HCHO ml^{-1}, *p*H adjusted to 6.5 at 37° C). The formaldehyde treatment was stopped after 6 d by neutralisation with equimolar sodium-disulphite ($Na_2S_2O_5$). The formaldehyde had inactivated 50–75% of the HVS specific CF antigens. The resulting suspension was concentrated 100-fold by dialysis against Aquacide (Calbiochem, Los Angeles). The concentrate was centrifuged at 12,000*g* for 10 min at 4° C (B 20 centrifuge, International Equipment, Boston) and the supernatant was stored at −60° C and used for vaccination. From each vaccine preparation (10 ml), 30% were tested for cytopathogenicity in OMK cells. No CPE appeared in these cultures during an observation period of 36 d.

In contrast to previously reported findings[5] small amounts of infectious HVS particles were found in our laboratory when the heat treatment of HVS at 56° C was stopped after 30 min. The survival curve of HVS is multicomponential after treatment with heat as well as after treatment with formaldehyde. For vaccine production this problem could be solved by prolonged incubation periods.

The killed vaccines were tested for infectivity, oncogenicity and antigenicity in CT marmoset monkeys. A distinction has to be drawn between infectivity and oncogenicity of herpesviruses since killed herpesvirus hominis induced neoplastic transformation *in vitro* without productive infection[6,7]. After being absorbed with Aluminiumhydroxygel (10% v/v of a 3% solution, Behringwerke, Marburg, West Germany) as adjuvant, nine CT marmosets were immunised. Four or five intramuscular inoculations of 1.0 ml each of the killed HVS concentrate were given to each animal within 4–6 weeks. The killed HVS vaccine in all these monkeys induced high titres of neutralising and CF antibodies against HVS (Table 1). The neutralisation tests were performed in OMK cell cultures with a constant serum dilution (1:5) and varying ten-fold virus dilution according to standard techniques[4]. The serum antibodies appeared about 3 weeks after the first inoculation and reached titres as high as those found in the sera of the three non-immunised control monkeys, who developed malignant lymphoma after inoculation of infectious HVS (Table 2). In contrast to the tumour-bearing monkeys (Table 2), HVS could

not be isolated from the immunised animals by cocultivation of fresh peripheral blood with OMK cells (Table 1). The vaccines proved not only to be free of infectious HVS, but also to be non-oncogenic. All of the immunised monkeys remained clinically well; two of them (174 A and 175 A) have been now under observation for 9 months (Table 1).

The immunised monkeys 174 B, 175 B and 191 B were challenged with $10^{3.8}$ $TCID_{50}$ of cell-free HVS (passed through a 450 μm Millipore filter) by intramuscular inoculation. Monkey 174 B died 61 d after infection, of an accident, without signs of malignant lymphoma. Animals 175 B and 191 B died 64 and 94 d post infection of a tumour which was characteristic for HVS in gross pathology and histopathology (Table 2). Three control monkeys who received the same HVS inoculation had already died 28, 30 and 33 d post infection because of malignant lymphoma (Table 2). This result indicates that the immunisation delayed the development of malignancy. Experiments are in progress to examine whether CT marmoset monkeys, actively immunised against HVS, are resistant to challenge with smaller doses of HVS than the very high challenge dosage already examined here.

These findings clearly demonstrate that a killed vaccine from oncogenic HVS can be prepared which is safe in respect to infectivity and oncogenicity. The immunisation of CT marmoset monkeys with the killed vaccine induced high titres of HVS specific serum antibodies and delayed tumour development after challenge with a very large dose of infectious HVS. The recent demonstration of induction of lymphomas in CT marmoset monkeys[8] and an owl monkey[9] by EB virus may aid in the extrapolation of our data in regard to the wanted vaccine against Burkitt's lymphoma in man.

Involvement of IgE in con A-induced histamine release from human basophils *in vitro*

CONCANAVALIN A (con A) induces the release of histamine from rat[1] and hamster mast cells[2] and human basophils. Time course, cationic requirements, enzymatic sequences and dose-response seem to be the same for con A-induced release as for antigen-induced release, which is mediated by reaginic antibody (reagin), believed to be bound by its Fc portion to a receptor in the membrane of the histamine-releasing cell. Human reagin is an antibody of the IgE class[3]. Antibodies[4] specific for IgE can induce histamine release whereas the papain digest[5] of those antibodies (which produces monomer anti-IgE) fails to elicit a response and can inhibit the intact anti-IgE-induced release[6]. The requirement for bridging to initiate histamine release has been established[7–13]. The types of sugar moieties to which con A binds have been studied[14–17], and the physicochemical properties of con A[15,18–22] indicate that at physiological *p*H it can bridge two or more of those sugar moieties. The question is raised as to whether con A is bridging sugar moieties at the receptor for reagin, or whether it is bridging sugar moieties which are directly attached to the reagin. The nature of the receptor remains to be established and the observation that con A can induce histamine release raised expectations that this interaction could elucidate some of the properties of this receptor.

The premise that con A is interacting with a receptor has been weakened by the report[1] that mast cells from rats immunised to produce high reaginic antibody released to con A whereas mast cells from nonimmunised rats did not. I report here that con A release from human basophils involves IgE. Antibodies specific for the Fc portion of IgE (Pharmacia) and antibodies specific for the Fab portion of human immunoglobulins (Behring) were used. They were papain-digested to a monomer form, and lost the ability to induce histamine release but not the ability to bind the IgE. The data show that release induced by con A (Pharmacia) can be inhibited by Fc-specific monomer anti-IgE but not by monomer anti-Fab (Fig. 1). This indicates that con A-induced release in human basophils is mediated by the Fc, but not the Fab, portion of the membrane-bound IgE. The fact that Fc-specific monomer anti-IgE-inhibited release is not conclusive evidence that con A is not bridging sugar moieties at the receptor for IgE. If the IgE receptor has sugar groups close to the Fc portion of IgE, then a steric hindrance of the con A by the monomer is a possibility. However, human basophils can be passively sensitised[23], which implies that not all the receptors for IgE are occupied. It is not likely that the monomer would sterically hinder the binding of con A to an unoccupied receptor. Since inhibition by the monomer is nearly complete, it indicates that either the receptor has no sugar moieties to which con A binds, or that the receptor must have an IgE molecule in place before an activation of the basophil can be mediated by it.

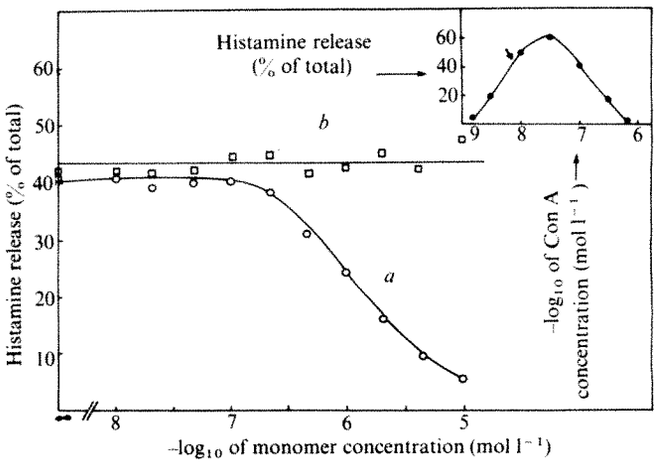

Fig. 1 Histamine release from the basophils of a nonallergic individual (A.A.). Cells were obtained by sedimentation of whole blood. The reaction was carried out at 37° C for 50 min in a Tris-buffered solution (*p*H 7.4) containing 0.03% human albumin, 1×10^{-3} M Ca^{2+}, 1×10^{-3} M Mg^{2+} and 2×10^{6} leukocytes per ml corresponding to 20–30 ng histamine base per ml (ref. 24). Supernatants were assayed for histamine by a spectrofluorometric technique[25,26]. Blanks were less than 5% of the total histamine content. In estimating the molar concentrations, 71,000 daltons[18] was assumed for con A, and 50,000 daltons[5] for the monomer preparations. *Inset*, histamine release induced by con A. The arrow on the dose-response curve indicates the concentration of con A (6×10^{-9} M) used to obtain the data in the other two curves. ○, The effect of increasing concentrations of monomer Fc specific anti-IgE (abscissa) on the release of a fixed amount of con A (6×10^{-9} M). □, The effect of increasing concentrations of monomer anti-Fab (abscissa) upon the release of a fixed amount of con A (6×10^{-9} M).

I thank Miss Alice Alexander for help in the preparation of the manuscript.

Possible role for the Fc receptor on B lymphocytes

B LYMPHOCYTES[1], polymorphonuclear cells[2], mast cells[3] and cells of the macrophage–monocyte[2] series possess surface receptors for the Fc portion of the immunoglobulin molecule. In some cases the functions of this receptor is clearly understood but this is not true for B lymphocytes. It has been suggested that the Fc receptor on B cells plays a role in the localisation of antigen in the form of antigen–antibody complexes[4]. We propose an alternative hypothesis that the Fc receptor on B cells is a membrane receptor (termed the proreceptor) for the immunoglobulin which functions as antigen receptor on these cells and present some evidence compatible with this hypothesis.

The plasma cell tumour MOPC 21 (P3) which secretes IgG1 kappa molecules in tissue culture[5] has surface immunoglobulins but lacks Fc receptors[6]. Mutants which secrete altered immunoglobulin molecules or no immunoglobulin can be obtained[7,8], and the nonsecretors lack surface immunoglobulin[6]. According to our hypothesis the apparent absence of Fc receptors on P3 cells would be due to the occupation of Fc receptors by surface immunoglobulin. If this was the case it would be expected that nonsecretors lacking surface immunoglobulin would show the presence of Fc receptors. The results of our investigations on several cell lines are summarised in Table 1.

This shows that in accordance with the hypothesis there is in general an inverse correlation between the presence of surface immunoglobulin and Fc receptors on the cell lines. However there is a variation in the intensity of the Fc receptor reaction on the different nonsecretor lines with X60 showing no reaction. The mutations leading to nonsecretion are unlikely to be simple and could also affect other aspects of cell function. The variation in the Fc receptor reaction could be a consequence of this. The cell lines IF1 and IF2 are more relevant as the mutations are likely to be more restricted to the structure of the immunoglobulin molecules. The weaker reaction on IF1 for surface immunoglobulin is accompanied by the appearance of Fc receptors. IF2 shows a weak Fc receptor reaction but there is no detectable decrease in surface immunoglobulin. This indicates that the C_H3 region is important in the binding of IgG to the Fc receptors. This was confirmed by using purified protein to inhibit Fc rosette formation. In the experimental conditions used, the wild type and IF2 protein are inhibitory while IF1 protein is not (Table 2).

Table 1 Properties of the cell lines

Cell line	Secreted molecules	Fc receptors	s Ig
P3	IgG	—	+ +
X27	IgG	—	+ +
X63	IgG	—	+ +
IF2	IgG with C_H1 region deleted	+	+ +
IF1	IgG with C_H3 region deleted	+ +	+
D1-20	Nonsecretor	+	—
Pr4	Nonsecretor	+	—
289-16	Nonsecretor	+ + +	—
X60	Nonsecretor	—	—

Surface immunoglobulin was detected with a fluorescein-conjugated IgG fraction of a sheep anti-mouse Fab and a rabbit anti-mouse IgG antiserum[6]. Fc receptors were detected by a rosette technique using bovine erythrocytes coated with mouse antibody as indicator cells[9–11]. Tumour cells were grown in RPMI 1640 medium (Flow Laboratories, Scotland) containing 15% foetal calf serum. X27 was a cloned cell line derived from a P3 culture. X63, IF1, Pr4 and 289-16 were cloned from X27 cells, while X60, D1-20 and IF2 were isolated from a P3 culture.

Because of variability from test to test, a four point scale is used to describe the Fc receptor reaction on different lines. + + + denotes in general a reaction on greater than 50% of live cells from a culture; + + a reaction on 10–50%; + a reaction on up to 10% of cells while negative is not significantly above controls with unsensitised indicator cells. The surface immunoglobulin staining on the secretor cells is weaker than on B lymphocytes and a two point scale is used to describe the intensity of staining.

The relation between surface immunoglobulin and Fc receptors found on the cell lines is consistent with our hypothesis provided that the surface immunoglobulin on secretor cells is not secreted immunoglobulin passively absorbed from the culture medium. Experiments where 289–16 cells were incubated with P3 IgG and then washed and stained with the rabbit anti-globulin showed that immunoglobulin could be passively absorbed. Taking advantage of the observation that rabbit IgG is recognised by mouse Fc receptors[4] we find that the presence of 10% rabbit serum can prevent absorbtion of mouse IgG from medium containing 50 mg ml^{-1} IgG. In contrast, the surface immunoglobulin on secretor cells is not lost from cells grown in 10% rabbit serum for up to 7 d. This shows that the surface immunoglobulin on the secretor cells is not passively absorbed.

The majority of B lymphocytes in mouse possess monomeric IgM receptors[9–11] but secreted IgM is found to only weakly inhibit Fc rosettes on B cells[1,12]. One explanation is that receptor IgM may have a higher affinity for Fc receptors than secreted IgM. This possibility is being investigated at present.

Reports in the literature indicate a large number of murine leukaemias of non-T-cell origin which possess Fc

Table 2 Inhibition of Fc rosettes on 289-16 cells with P3, IF1, and IF2 proteins

Inhibitor	% reacting cells ±s.e.	% inhibition
Nil	24.0 ± 4.2	—
P3(580 μg ml^{-1})	5.8 ± 1.7	75.5 $P < 0.05$
IF1(580 μg ml^{-1})	5.8 ± 1.7	1.7 (P not significant)
IF2(580 μg ml^{-1})	6.4 ± 3.5	73.4 $P < 0.05$

receptors but no surface immunoglobulin[6,14]. A light chain secreting variant of a plasmacytoma is also found to be Fc receptor positive[1,12]. In patients with X-linked agammaglobulinaemia cells are found which lack surface immunoglobulin and possess Fc receptors[15,16]. We suggest that these may also be cases where the Fc receptors are exposed in the absence of immunoglobulin.

Finally we would like to suggest that in view of the observations that antigen–antibody complexes can induce nonspecific transformation in lymphocytes[17] it is possible that the specific activation of B cells by antigen is mediated through proreceptors.

We thank R. G. H. Cotton and Shirley Howe for the cell lines and the Cancer Research Campaign for support. R. R. was supported by a Wellcome Trust studentship.

Con A differentiates among grass pollens by binding specifically to wall glycoproteins and carbohydrates

AIRBORNE grass pollens are a major cause of hayfever. The allergens involved are mostly proteins and glycoproteins[1,2], which are stored in pollen walls[3] and rapidly released on moistening and which seem to play a recognition role in pollen/stigma interactions[4]. The capacity of certain plant lectins to bind specific carbohydrates and glycoproteins[5] and form precipitates with them in double diffusion tests[6,7] indicates a means of investigating these substances in pollen. We report here how concanavalin A (con A), the lectin from jack beans, *Canavalia ensiformis*, differentiates among grasses by specifically precipitating wall-held materials from pollens mainly of nonfestucoid species. Furthermore, pollen of corn (*Zea mays*) and its closest relatives is easily distinguishable from that of other grasses by its characteristic reactions with con A.

We have used double diffusion tests to screen grass pollen from 42 species (33 genera, including many known to be important sources of allergens) for materials precipitating with con A. Extracts from 9/42 species have given clear precipitation lines against con A (Table 1). The contrast between festucoids (1/23 reacting clearly) and nonfestucoids (8/19) is marked. In addition, the reacting andropogonoids and *Cynodon* give denser precipitates than the rest, while Maydeae alone (*Zea, Euchlaena, Tripsacum*) produce two definite bands against con A (Fig. 1*c*). The relatively faint precipitates with *Festuca, Phragmites, Stipa* and *Echinochloa* are consistently reproducible (Fig. 1*a* and *b*). When diffusates of the positively-reacting pollens of *Cynodon, Sorghum, Zea* and *Festuca* and of the negatively-reacting *Lolium perenne* were concentrated by ultrafiltration and partially purified by Sephadex G25 chromatography, *Lolium* continued to give a negative result, *Cynodon* now gave no reaction while the two andropogonoids and *Festuca* precipitated con A as before. The *Cynodon* reaction probably involves carbohydrate diffusates rather than glycoproteins, and other faintly-precipitating species (where shortage of pollen has precluded more detailed tests) may fall into the same category. A high molecular weight *Zea* fraction (>10,000 daltons) shows two intense precipitation bands (Fig. 1*d*), there being only slight precipitation in a lower molecular weight fraction probably containing carbohydrates.

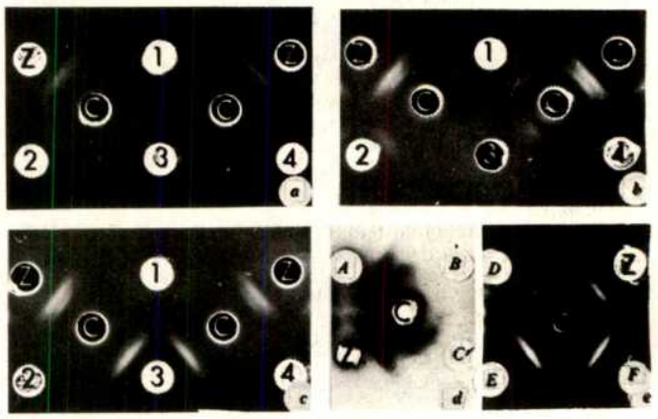

Fig. 1 Double diffusion tests of grass pollen extracts (outer wells) against con A (inner wells). Extracts prepared as in Table 1. *a*, *Festucoids*: 1, *Lolium multiflorum;* 2, *Festuca rubra;* 3, *Poa annua;* 4, *Bromus inermis. b*, Nonfestucoids: 1, *Phragmites australis;* 2, *Cynodon dactylon;* 3, *Stipa falcata;* 4, *Danthonia eriantha. c*, Nonfestucoids: 1, *Sorghum halapense;* 2, *Coix lacrymajobi;* 3, *Euchlaena mexicana;* 4, *Setaria geniculata.* Arrows indicate faint precipitin lines. *d*, Reactions of con A to various *Zea* diffusate fractions. After Sephadex G25 gel filtration, *A*, a high molecular weight fraction (>5,000 daltons) shows two clear bands; *B*, a low molecular weight fraction (<5,000 daltons) shows no precipitation band; *C'*, a fraction from ultrafiltration with a molecular weight of >10,000 daltons, showing precipitation corresponding to inner band of the pair present with whole extract. *e*, Reactions of con A to *Zea* extracts after proteolytic digestion or heat treatment. *D*, after treatment with insolubilised pronase; *E*, after treatment with papain; *F*, after incubation for 1min at 100° C. *a*, *b*, *c*, and *e*, photographed by dark field illumination of unstained gels; *d*, dried gel stained with Coomassie Blue. Z, *Zea mays*; C, con A.

The two lines against *Zea* extracts are probably con A-bound glycoproteins, as one is eliminated and the other rendered fainter by previous treatment with pronase (Fig. 1*e*). Preliminary experiments show that the con A-bound substances are antigenic and correspond in electrophoretic

mobility with two of the five antigens we have detected with high titre rabbit antiserum to *Zea* pollen diffusate[8]. Con A continues to precipitate extracts after incubation for 1 or 20 min at 100° C (Fig. 1*e*) and it is interesting that similar heat stability is also characteristic of some of the 'I' antigens, considered to be the main allergens of other grass pollens[1,9].

When pollen is sprinkled on con A gels, both *Zea* and *Euchlaena* grains show radially-aligned wisps of precipitate within 2 min (Fig. 2*a*). After 3 h, intense deposits of precipitate were evident (Fig. 2*b*). These reactions do not occur in control preparations without con A (Fig. 2*d*), and when other pollens are mixed with *Zea* as controls of specificity (Fig. 2*c*) conspicuous precipitates form only around the *Zea* grains even after 24 h incubation. We have also modified immunofluorescence procedures for pollen antigen location[10,11], to detect sites of con A binding to glycoproteins or carbohydrates in freeze-sectioned *Zea* and *Tripsacum* grains. Intensely-fluorescing precipitins appeared only in pollen wall sites (Fig. 3*a*), on the surface of the outer exine and in the inner cellulosic intine layer, and were absent from appropriate controls (Fig. 3*b*). The diffusible antigens of *Phalaris tuberosa* pollen have been located in these same sites[3], and show characteristic release kinetics. Immediately grass pollen grains are moistened, proteins and glycoproteins stored in cavities of the exine are released through surface micropores[4]. Only after about 3 min do those of the inner intine begin to be released, through the single pore or germinal aperture. While *Zea* and *Euchlaena* pollen precipitates con A within 2 min of moistening, the considerable increase in precipitation by 3 h indicates the involvement of both wall fractions. The immunofluorescence experiment seems to confirm this.

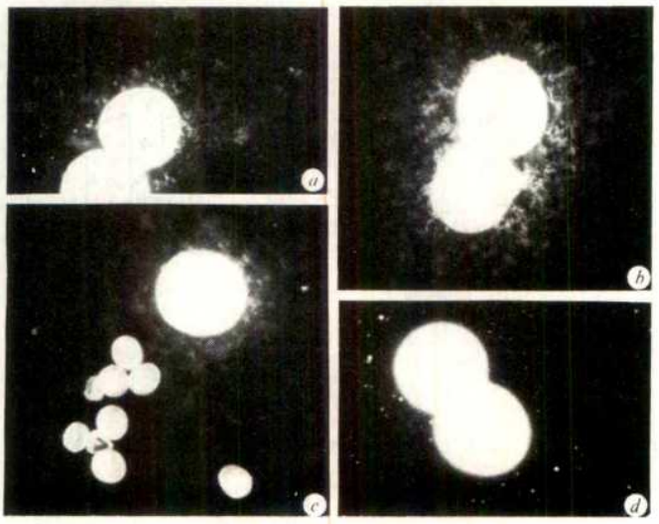

Fig. 2 *Zea* pollen sprinkled on 0.5% agarose gels containing 2 mg ml^{-1} con A and 0.2 M NaCl, viewed by dark field microscopy: *a*, After 2 min showing precipitate around grain; *b*, after 3 h showing dense radiating precipitates; *c*, mixture of *Zea* and *Lolium* pollen after 3 h with precipitation confined to the large *Zea* grains and absent from *Lolium* grains (in sharp focus); *d*, control with *Zea* grains sprinkled on gels without con A. (× 270).

It is not widely known that allergic persons often show taxonomically-patterned responses to festucoid, chloridoid, panicoid and andropogonoid grasses (refs 12, 13 and unpublished data). Methods have not yet been devised for distinguishing airborne grass pollens so it remains unclear how far this phenomenon results merely from factors affecting atmospheric availability of pollen for sensitisation. Our observations with con A, however, are consistent with the possibility that it directly reflects taxonomically-ordered variation in the allergenic components of pollen grains, as

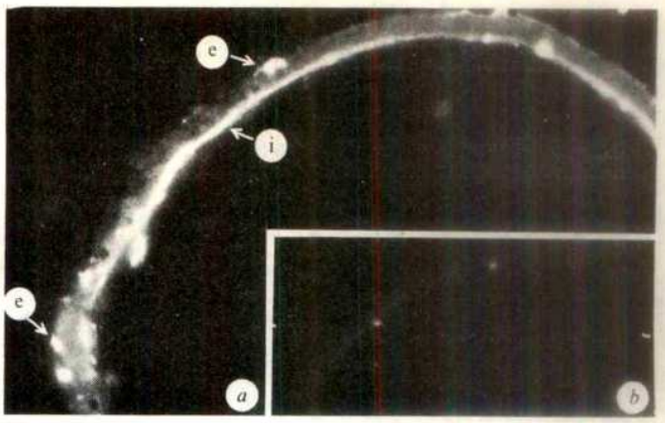

Fig. 3 Immunofluorescence localisation of con A-binding substances in freeze-sectioned *Zea* pollen, fluorescence image. *a*, Section treated with con A (40 min), saline rinse (15 min), rabbit anti-con A serum (40 min), saline rinse (15 min), FITC-labelled anti-rabbit γ-globulin serum (40 min); fluorescing precipitins present in intine (i) and surface exine cavities (e) but absent from protoplast; *b*, control section treated with con A, saline rinse, normal rabbit serum, saline rinse and FITC-labelled anti-rabbit γ-globulin serum, no fluorescing precipitins evident. (× 900)

are the findings of Augustin[13] and Marsh *et al.*[9] who, while working mostly with festucoids, have found a few non-festucoids to be immunologically very distinct. Such taxonomic predictability needs pursuing in detail, as it has medical potential for detecting cross reactions among allergenic pollens and for efficient selection of appropriate extracts or allergoids[14] for desensitisation therapy. It also points to the need in atmospheric pollen counts to try and identify the grasses, at least to major group level, and Fig. 2*c* indicates how further work with other lectins may help.

Many of the materials released when pollen is moistened, including proteins, glycoproteins and carbohydrates, function in early germination processes on the stigma. In *Phalaris tuberosa*, rapidly-released antigens bind to the stigma surface[3]. They seem to act in a variety of ways as pollen/stigma recognition substances[4], being concerned in regulating the breeding system. It is therefore intriguing that pollens of cultivated corn (*Zea mays*) and species directly involved in its evolution (*Euchlaena, Tripsacum*)[15] produce an identical and unique reaction with con A.

Table 1 List of grass pollen extracts tested with con A by double diffusion in agarose

Festucoids
Agropyron repens, *Agrostis tenuis*, *Anthoxanthum odoratum*, *Avena barbata*, *Bromus carinatus*, *B. inermis*, *B. rigidus*, *Dactylis glomerata*, *Elymus condensatus*, *E. triticoides*, **Festuca rubra**, *Holcus lanatus*, *Hordeum vulgare*, *Lolium multiflorum*, *L. perenne*, *L. temulentum*, *Phalaris arundinacea*, *Ph. minor*, *Ph. tuberosa*, *Poa annua*, *P. pratensis*, *P. scabrella*, *Secale cereale*

Chloridoids
Bouteloua sp., *Chloris truncata*, **Cynodon dactylon**, *Distichlis spicata* *Sporobolus aeroides*

Arundinoid—Danthonioids
Danthonia eriantha, **Phragmites australis, Stipa falcata**

Panicoids
Echinochloa crus-galli, *Paspalum dilatatum*, *Pennisetum villosum*, *Setaria geniculata*

Andropogonoids
(1) Andropogoneae: *Saccharum officinarum*, **Sorghum halapense,** *Themeda australis*
(2) Maydeae: *Coix lacrymajobi*, **Euchlaena mexicana, Tripsacum floridanum Zea mays**

Those showing precipitation appear in **bold face.** 0.2 g ml^{-1} dry pollen (obtained from Greer Laboratories, Lenoir, North Carolina; Commonwealth Serum Laboratories, Melbourne, Australia, and collected by us) extracted in 0.2 M NaCl in 0.05 M tris buffer, *p*H 7.5 for 20 min at room temperature. Con A (Pharmacia) used at 2 or 5 mg ml^{-1} in same buffered saline.

In *Silene* the pollen wall proteins bind to the stigma surface pellicle, a protein overlay found in most if not all angiosperms and which is the probable site of recognition reactions determining acceptance or rejection[16]. An interpretation of the situation in *Zea* and its closest relatives open to experimental testing (comparable with mammalian sperm/egg recognition[17]) is that the stigmatic surface receptors may possess specific determinants similar to those of con A.

Absence of adenine nucleotide release from autonomic ganglion

SYNAPTIC vesicles isolated from Torpedo electroplaques contain ATP as well as acetylcholine (ACh)[1,2]. Silinsky and Hubbard[3] showed that ATP is released from the rat hemidiaphragm bathed in a hyperosmotic medium and they suggested that the motor nerve terminal releases ACh and ATP simultaneously. Here we report tests for the release of ATP and ACh from the cat superior cervical ganglion; we demonstrated that ACh, but not ATP, is released during stimulation.

The superior cervical ganglion of the cat was perfused[4,5] either with 'normal' Krebs solution (composition in mM: NaCl, 120; KCl, 4.6; $CaCl_2$, 2.4; $NaHCO_3$, 25; KH_2PO_4, 1.2; $MgSO_4.7H_2O$, 1.2; glucose, 9.9; neostigmine bromide, 0.03) or with a Krebs solution that did not contain $CaCl_2$ or $MgSO_4$ but contained 1 mM EDTA and 3 mM $BaCl_2$. This 'modified' Krebs solution was used to inhibit Ca^{2+}, Mg^{2+} dependent ATPase activity, and it contained Ba^{2+} to provide the divalent cation requirement for ACh release[6]. The release of ACh was evoked either by stimulating the preganglionic sympathetic trunk (20 Hz, 0.3 ms, 5.5 V) or by raising the KCl concentration in the perfusion medium to 50 mM (in which case the NaCl concentration was reduced to 50 mM). The effluent from the ganglion was collected in 5 min aliquots and each sample was assayed for ATP and for ACh. ATP was assayed using a modification of the luciferase method[7] that permitted the determination of as little as 4 pmol ATP; ACh was measured by bioassay on the cat blood pressure[8]. In some experiments adenosine monophosphate (AMP) or adenosine diphosphate (ADP) was measured instead of ATP; they were measured by the luciferase method after being converted to ATP enzymatically[9]. The conversion of AMP or ADP to ATP was checked by thin-layer chromatography[10] using ^{14}C labelled standards.

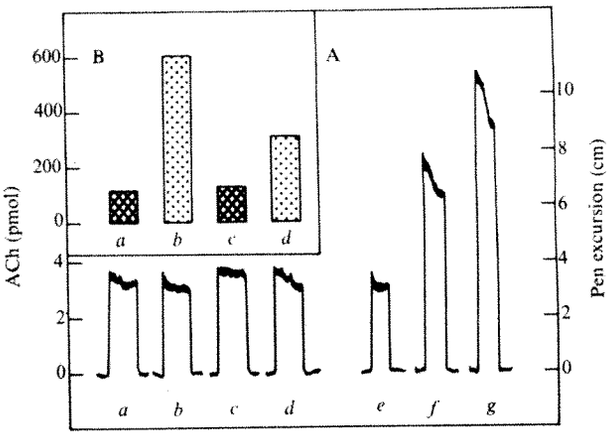

Fig. 1 A, Chart record of light emitted in the ATP assay of perfusate collected from the ganglion during *a*, rest; *b*, stimulation by high K^+; *c*, rest; *d*, preganglionic nerve stimulation. *e*, Control sample of 'modified' Krebs solution with no added ATP; *f*, 7.5 pmol ATP added to 'modified' Krebs medium; *g*, 12.5 pmol ATP added to 'modified' Krebs medium. ATP was assayed as follows. A plastic vial containing 1.5 ml of the sample to be assayed was placed in a light-tight housing system which was connected to a photomultiplier (American Instrument Co., USA) and to a Texas Rectiriter pen recorder. The reaction was initiated by injecting 1.0 ml of firefly lantern extract (Sigma, 5 mg ml^{-1} dissolved in 0.15 M Na_3AsO_4 buffer, *p*H 7.5, containing 0.1 M $MgSO_4$) into the vial through a rubber seal on the top of the housing system. B, The amount (pmol) of ACh contained in the same samples measured on the blood pressure of the eviscerated cat[8]. Before measuring the ACh content of the perfusion medium, barium ions were removed by the addition of 1/10 volume of 0.15 M Na_2SO_4; the precipitated $BaSO_4$ was removed by centrifugation and the supernatant was used for bioassay.

Figure 1 illustrates the result of a typical experiment which measured the release of ACh and ATP by nerve stimulation or by raised K^+ during perfusion with 'modified' Krebs solution. Although ACh was released by perfusion with high K^+ or by nerve stimulation, ATP could not be detected during the stimulation or rest period. Six other experiments confirmed this result. At the end of each experiment, a known concentration of ATP (60 pmol ml^{-1} in 'modified' Krebs solution) was perfused through the ganglion to determine the extent of breakdown. This usually was 10–25%. In contrast, when normal Krebs plus ATP or Krebs medium containing 0.1 mM Ca^{2+} plus ATP (no Mg^{2+}) was perfused through the ganglion, none of the ATP survived degradation. Whittaker *et al.*[1] found that the mean ACh:ATP molar ratio was 11:1 in synaptic vesicles from Torpedo electroplaques. If this ratio were the same

in transmitter stores of cat ganglion, and if all of the ATP were released during stimulation, then in our conditions, in which 150–650 pmol of ACh was released, 14–59 pmol of ATP should have been released; this quantity of ATP would have been readily detected under the conditions of our experiments. It is interesting that ATP release was detected immediately following a change of perfusion medium from a normal Krebs to a 'modified' Krebs solution. At this time a transient depolarisation of the postganglionic fibres occurred, causing a contraction of the nictitating membrane and about 15 pmol of ATP was released; no ACh was released during this period. We did not determine the origin of this ATP.

Other experiments were designed to test the release of ADP or AMP when perfusion was with normal Krebs medium and ACh release was evoked by nerve stimulation. In all experiments, ACh was released during nerve stimulation, but no ADP or AMP release could be detected. At the end of each experiment, ADP or AMP of known concentration was perfused through the ganglion, collected and analysed to determine the extent of breakdown. The ADP and AMP were degraded by 25% and 10% respectively.

In conclusion, we were unable to reproduce the results of Silinsky and Hubbard[3] using a different mammalian preparation. It is possible that the ATP detected in their experiments originated from the muscle rather than from the nerve terminal, as suggested by other workers[11–13]. The perfusion of the superior cervical ganglion avoided any artefacts arising from the presence of muscle, and allowed the collection of more ACh than could be collected from the stimulated rat phrenic nerve diaphragm preparation.

Pattern of remyelination in the CNS

It has been suggested that reduction of internodal length may be a feature of remyelinated central nerve fibres as it is of peripheral nerve fibres[1]. As the technique for measuring internodal length of nerve fibres in the central nervous system (CNS) is tedious and requires a high degree of skill and patience from the investigator[2], it is unlikely that this method can be applied to routine neuropathological investigations. Recent ultrastructural studies on remyelination in the mouse, following primary demyelination induced by feeding cuprizone (Bis - cyclohexanone - oxaldihyrozone)[3–5] have shown that measurements of the relationship between myelin sheath thickness and axon diameter provides an easier method of identifying remyelinated axons.

Male weanling albino mice of the ICI strain were fed on a powdered mouse diet containing 0.6% cuprizone. Two mice were killed after 6 weeks to assess the extent of demyelination in the superior cerebellar peduncle (SCP) (ref. 3) (Table 1). As both did not show complete demyelination the remaining nine animals were left on the cuprizone-containing diet for a further 2 weeks. At this time two animals were killed and examined for demyelination. Nearly all fibres in the SCP were demyelinated (Table 1), so the remaining seven animals were placed on a normal diet (previous experiments having shown that under these circumstances remyelination readily takes place[4,5]). Mice were then killed at the times indicated in Table 1 and remyelination assessed. Normal mice of two different ages were also killed and examined in the same way as the experimental animals. All animals were perfused with 4% glutaraldehyde in phosphate buffer and blocks were taken

* In regression equation: $\bar{y}$ = mean myelin sheath thickness; $\bar{x}$ = mean axon diameter; byx = slope of linear regression of myelin sheath thickness on axon diameter; x and y were measured in mm on electron micrographs at 7,200 magnification; y = actual measurement × 10.
† Indicates the three animals depicted graphically in Fig. 1.
d = diameter of axon; D = diameter of fibre.

which contained the SCP cut in transverse section at the point where it passes under the middle cerebellar peduncle[3,4]. Thin sections were prepared for electron microscopy and six electron micrographs were taken at random of the SCP at a magnification of 1,800. These were enlarged photographically a further four times and the following parameters measured: percentage of myelinated fibres, myelin sheath thickness and axon diameter. These were determined for a representative sample of fibres by methods used previously[3,4]. Table 1 gives values for the percentage of myelinated fibres in the SCP, the d/D ratio (diameter of axon/diameter of fibre)—an index of myelin sheath thickness—the slope of the linear regression of myelin sheath thickness on axon diameter, and the correlation coefficient of myelin sheath thickness and axon diameter. An analysis of the significances of differences between the regression lines was carried out[6].

Nearly all axons are remyelinated during the recovery period and with time the myelin sheath increases in thickness (Table 1). But even after six months recovery, myelin sheath thickness has not returned to its normal relationship with axon diameter (Table 1, Fig. 1). There is a significant difference between the index of myelin thickness for the 6 month remyelinated animals and the 2-month-old control animals. Taking into account that the 6-month-recovery animals are 10 months old, it can be seen that the remyelinated axons have much thinner myelin sheaths than would be expected for animals of their age. In addition the slopes of the regression lines for the remyelinated animals are significantly different (at the 0.01 level; sample size 32–47 observations) from either young or old control animals. It seems therefore that although myelin sheath thickness does increase with time in remyelinated animals, it does not return to its normal relationship with axon diameter for a considerable length of time. It is likely, therefore, that the presence of an axon within a myelin sheath which is thinner than would be expected for the diameter of the contained axon, represents a remyelinated fibre. Such an observation will have little significance when applied to a single fibre, but if it can be shown that the axon diameter–myelin sheath thickness relationship for a population of fibres is abnormal, or that two populations of fibres coexist in a single tract then it can be reasonably assumed that remyelination has taken place on the axons possessing thinner than normal myelin sheaths. This experiment supports the many observers who have stated that axons within thinner than normal myelin sheaths represent remyelinated axons[7–12] and suggests a simple method for determining the extent of remyelination in man.

Effect of intracellular lithium on snail neurones

It is well established that lithium salts are effective in the treatment of manic depressive illness[1,2], but the way they act is little understood. Some time ago, as part of a study on the electrogenic sodium pump, it was noticed that high levels

of intracellular Li^+ or Na^+ seemed to increase the potassium conductance of the snail nerve cell membrane[3,4]. Because of the greatly increased interest in Li^+ itself, we have now confirmed the original observations, and have shown that detectable effects occur at quite low levels of intracellular Li^+. Such an increased membrane conductance to potassium would tend to decrease the membrane excitability and hence stabilise the cell. If a similar response to intracellular Li^+ occurs in man, it could be the basis for its therapeutic effects.

We performed our experiments on the largest nerve cell at the rear of the right pallial ganglion of the common snail *Helix aspersa*. The brain was dissected from dormant specimens and pinned in a chamber where it was bathed in continuously flowing snail Ringer (KCl, 4 mM; NaCl, 80 mM; $CaCl_2$, 7 mM; $MgCl_2$, 5 mM; Tris-maleate (*p*H 7.5), 20 mM) at room temperature (14–21° C). The bathing solution could be quickly changed to Ringer containing various concentrations of potassium or to normal Ringer with 10^{-4} M ouabain by means of a multiposition tap. The cell was impaled with one double and two single-barrelled microelectrodes. This allowed for the recording of membrane potential, the determination of input resistance by injected current pulses, and the interbarrel injection of LiCl, NaCl or KCl into the cell. In this last technique, current is passed between two intracellular electrodes, ejecting cations from one electrode and anions from the other.

Cell diameter was measured and cell volume calculated assuming a spherical cell. The amplitude and length of the interbarrel injection current was recorded and thus the amount of salt injected could be estimated. (For a more detailed description of these methods, see Thomas[5].)

The effect of a relatively large injection of LiCl is shown in Fig. 1. With the intracellular Li^+ concentration raised to a calculated level of 29 mM, the membrane potential was increased by about 3 mV, and the cell's spontaneous action potentials ceased. (Larger effects were seen with larger injections of LiCl, but in this experiment injection was stopped when the cell ceased firing to ensure reasonably rapid recovery.) There was a simultaneous one-third reduction in input resistance, as is shown by the decrease in the size of the hyperpolarisations resulting from the current pulses. Following the injection, both input resistance and membrane potential gradually returned to their resting values and spontaneous action potentials returned. The lowered resistance after LiCl injection recovered approximately exponentially. The time constant for the recovery shown in Fig. 1 was 40 min. Similar effects were seen in 29 cells, although in several cases the cell did not recover after the injection.

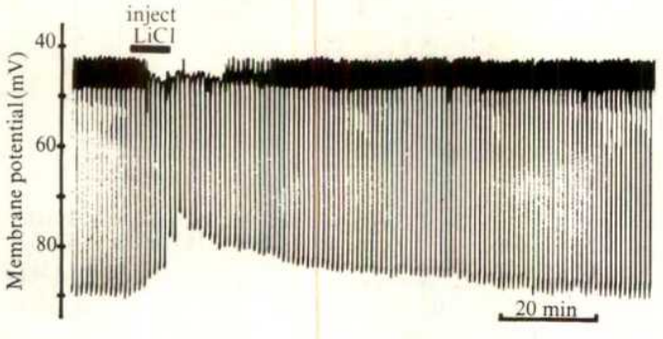

Fig. 1 Pen recording from an experiment to show the effects of injected LiCl on the input resistance of a spontaneously active snail neurone. The slow time response of the recorder has reduced the apparent size of the action potentials to only a few millivolts. Every minute a 5 nA hyperpolarising current was passed across the cell membrane for 10 s to measure the input resistance. The solid bar indicates the 8 min period during which an interbarrel injection current of 25 nA was passed. The cell diameter was 0.2 mm, so that this injection would be expected to raise the intracellular Li concentration by about 29 mM.

We also tested the effects of large injections of KCl and NaCl. An injection of KCl which would be expected to raise the internal K^+ concentration by about 45 mM caused only a slow depolarisation of a few millivolts with no change in input resistance. The injection of NaCl produced a more complex and variable result. Small injections of NaCl consistently caused an immediate ouabain-sensitive hyperpolarisation (as expected from the consequent stimulation of the electrogenic Na pump[4]) with no appreciable change in input resistance. Large injections of NaCl (giving a concentration greater than 20 mM), however, often produced both a considerably greater hyperpolarisation, which was little affected by ouabain, and a noticeable decrease in input resistance.

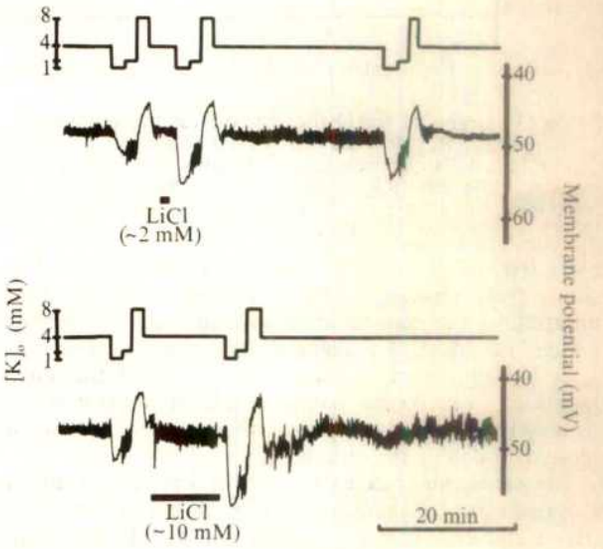

Fig. 2 The effect of injected LiCl on the sensitivity of a snail neurone to changes in external potassium. Two segments from a continuous record showing the effects on the membrane potential of brief exposures to 1, 2 and 8 mM external potassium. The normal external potassium concentration ($[K]_o$) was 4 mM. LiCl was iontophoretically injected where indicated by the solid bars, giving estimated internal concentrations of 2 and 10 mM.

Another way of describing the experiment shown in Fig. 1 is to say that the cell was being held, alternately, at two membrane potentials; one, the resting level at the top of the current pulses (−45 mV) and the other a more hyperpolarised level at the bottom of the pulses (−90 mV). Following a LiCl injection, then, the resting cell is seen to hyperpolarise while a cell held at a hyperpolarised potential depolarises, thus indicating the existence of an equilibrium potential for the process. The large injections of Cl^- which accompany these Li^+ injections would cause the chloride equilibrium potential to be less negative than the resting potential. Potassium is the only ion whose equilibrium potential would be in the range to produce these effects, although some involvement of other ions cannot be ruled out.

Figure 2 shows an experiment where the external K^+ concentration ($[K]_o$) was changed before and after two injections of LiCl. Although quite large injections are necessary to produce the marked changes in input resistance seen in Fig. 1, measurable changes in the relative potassium permeability (P_K) can be produced by much smaller injections. Following both LiCl injections in Fig. 2 the membrane potential becomes more responsive to a change in external K^+. As the injected Li^+ leaves the cell, this increased sensitivity declines gradually to the resting level.

Estimates in the change in P_K before and after LiCl injections, assuming no change in other ion permeabilities, were obtained from linear regression fits to $[K]_o$ against $\exp(FV/RT)$

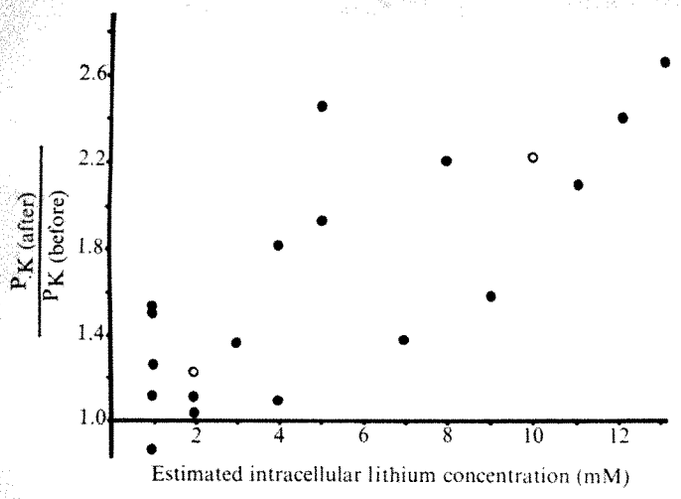

Fig. 3 Graph of the changes in the relative potassium permeabilities (P_K) of snail neurones as a function of estimated intracellular Li concentration. Relative P_Ks are calculated from plots of $[K]_0$ against $\exp(FV/RT)$. Results from 20 injections in seven cells; ○, points calculated from the data shown in Fig. 2.

plots (ref. 6) of 20 LiCl injections in seven cells. Figure 3 shows these changes in P_K as a function of the estimated intracellular Li^+ concentration. Although there is considerable scatter, the trend of a rising P_K following successively larger LiCl injections can be clearly seen. Thus intracellular Li^+ injections giving concentrations of a few mM cause measurable increases in P_K and injections of greater than about 8 mM more than double the resting P_K.

The extracellular concentration of Li^+ that is effective in the treatment of manic depressive illness is around 1 mM (refs 1 and 2). It seems possible that at least some neurones in the human brain will tend to concentrate Li^+ intracellularly, as passive distribution alone would give an internal level of about 10 mM in a cell whose resting potential was 60 mV, and the Na–K pump does not extrude Li[4]. Thus, if intracellular Li^+ has the same effect on some human neurones as on snail neurones, its therapeutic effects could arise from the membrane stabilising effects of the increased potassium permeability.

How does Li^+ cause this rise in potassium permeability? Perhaps the most likely mechanism is by an increase in the intracellular ionised Ca^{2+}. Meech[7] has shown that the injection of $CaCl_2$ into mollusc neurones causes a rise in their potassium permeability, and similar responses have been seen with mammalian motoneurones[8]. There is also evidence that Ca^{2+} is normally extruded from nerve cells by a Na–Ca exchange system[9], so that a rise in intracellular Na^+ will tend to cause a rise in intracellular Ca^{2+}. If Li^+ can substitute for Na^+ in this system then intracellular Li^+ would tend to cause an increase in intracellular Ca^{2+}. We have some preliminary evidence that intracellular calcium is involved, as we have found that the injection of EGTA partially reverses the change in P_K following a large lithium injection.

Periodicity in high sulphur proteins from wool

In a recent publication[1], Elleman, Lindley and Rowlands claimed that there is no evidence to support the view that high-sulphur proteins from wool have a common ancestral protein partly composed of a repeating unit of five amino acids[2,3]. Their evidence for a repeating decapeptide unit is restricted almost entirely to the region between residues 22 and 64 of protein SCMKB2B. Although the C terminal region of this sequence shows some correlation to the repeating decapeptide unit, it correlates better with a pentapeptide repeating unit as shown previously (ref. 3).

It is informative to compare the 'decapeptide rich' regions of the sequences of the three homologous SCMKB2 proteins[4] as shown in Fig. 1. Protein B2C contains two decapeptide repeating units while B2B and B2A contain three and four units, respectively. These differences probably resulted from gene elongation due to unequal crossing over of DNA during meiosis. The original decapeptide unit would then have been two adjacent pentapeptide units differing as a result of mutations. This would explain the 'partial symmetry' referred to by Elleman *et al.*[1].

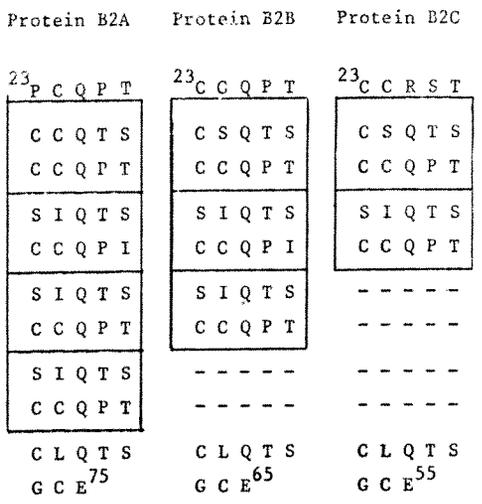

Fig. 1 The partial amino acid sequences[4] of protein SCMK-B2A (residues 23–75), protein SCMK-B2B (residues 23–65) and protein SCMK-B2C (residues 23–55) from the high-sulphur fraction of Lincoln wool, arranged to show maximum homology based on a pentapeptide repeat. The single letter notation for amino acids[5] has been used.

Lindley and Elleman[6] showed homology between 14 residues at the C terminal regions of the IIIB and B2 proteins. This homology was further extended by aligning a part of the sequence of protein IIIA3 with these regions[3], which proves a common origin for all these high-sulphur proteins. Yet Elleman *et al.*[1] derived different homologous decapeptide units for proteins IIIA3 and B2B, and none for the IIIB proteins, which they claimed to be random. We found[3] a single primordial pentapeptide unit, Cys-Cys-Gln-

Pro-X, which fits the IIIA3 and B2 groups of proteins equally well and, in addition, nearest neighbour statistical analysis shows that the sequences of the IIIB proteins are not random and are derived from the same unit with a probability of the order of 8×10^6 to one.

Platelet-activating factor, a new mediator of anaphylaxis and immune complex deposition from rabbit and human basophils

AN increase in vascular permeability as a result of the release of vasoactive amines has been implicated as a 'trigger mechanism' of immune complex deposition[1,2]. Several immunological mechanisms of vasoactive amine release from rabbit platelets have been described[3]. Experiments have correlated the presence of one of these mechanisms, a complement-independent, leukocyte-dependent reaction, with the vascular deposition of complexes in acute[4] and chronic[5] serum sickness of rabbits. We have obtained direct evidence that this mechanism is due to basophils sensitised with IgE (ref. 6). Antigen-induced *in vitro* degranulation of basophils from rabbits immunised with peroxidase yielded a soluble factor (platelet-activating factor (PAF)) which aggregated rabbit platelets in leukocyte-free solutions[6]. Here we describe several characteristics of rabbit PAF and a PAF-like factor obtained from human leukocytes.

Procedures used to obtain PAF from rabbit leukocytes have already been described in detail[6]. Briefly, buffy coat from rabbits immunised with peroxidase was cleared of erythrocytes by sedimentation in phosphate buffered saline (PBS) with 2.5% gelatin followed by osmotic shock, and cleared of platelets by repeated low speed centrifugation. Leukocytes were incubated in Tris-buffered Tyrode's solution (*p*H 7.4), with 0.25% bovine serum albumin (TTBSA), in the presence of antigen for 15 min at 37° C. Absence of platelets in buffy coat and addition of BSA to the medium as a PAF carrier are prerequisites for recovery of PAF. Cell-free supernatant was obtained by centrifugation, dialysed with 0.01 M phosphate buffer (*p*H 8.0), chromatographed on a DEAE-Sephadex A 50 anion exchange column, with a gradient of NaCl. PAF activity, measured in an aggregameter by aggregation of rabbit platelets in Tyrode's added with 0.25% gelatin (TG), was eluted with BSA. After dialysis with 0.01 M Tris 0.15 NaCl buffer (*p*H 7.4), PAF was separated from BSA by precipitation in 80% ethanol. After centrifugation at 60,000*g*, the supernatant was evaporated to dryness and PAF was resuspended in 80% ethanol. Throughout purification and characterisation of PAF, controls were TTBSA with leukocytes and peroxidase but maintained at 4° C for 15 min, instead of 37° C, or TTBSA without Ca^{2+} and Mg^{2+} used instead of TTBSA in the usual degranulation method. In a second step, leukocytes used for preparation of control buffers were resuspended in TTBSA at 37° C to release PAF in the presence of peroxidase.

PAF in 80% ethanol was filtered through a Sephadex LH 20 column equilibrated with 80% ethanol at *p*H 9.5. Markers were ^{125}I-labelled glucagon, bacitracin, vitamin B_{12}, ^{3}H-angiotensin and PSP. PAF from rabbit leukocytes (R-PAF) was eluted between vitamin B_{12} and angiotensin, exhibiting an apparent molecular weight of 1,100.

PAF filtered through LH20 in 80% ethanol was evaporated to dryness and resuspended in distilled water or 80% ethanol. PAF activity disappeared from distilled water-containing tubes in about 24 h, whereas PAF activity remained unchanged in 80% ehtanol for several weeks at 4° C. Varying the *p*H of distilled water between 5 and 10 did not influence the decrease of PAF activity. To explore this phenomenon further, the same experiment was carried out in distilled water, using tubes used for platelet aggregation. Tubes from which PAF activity had disappeared were emptied, rinsed once and filled with TG. Platelet aggregation occurred in these tubes, showing that PAF in distilled water had been adsorbed on the plastic walls of the tubes. No PAF activity was found on the walls of the tubes which had contained PAF in 80% ethanol. This result indicated that further studies of PAF had to be carried out in 80% ethanol.

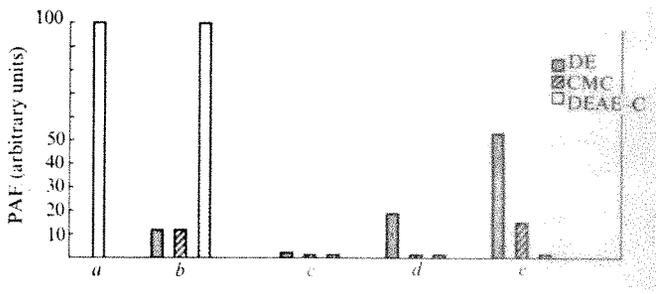

Fig. 1 Adsorption of PAF on charged particles in 80% ethanol. PAF activity was measured by aggregation of 3×10^7 rabbit platelets in 0.3 ml Tyrode's in an aggregameter (Icare, Marseille, France). *a*, Supernatants before adsorption at *p*H 6.50; *b*, Supernatants after adsorption at *p*H 6.50; *c*, elution from washed particles at *p*H 7.00; *d*, at *p*H 8.00; *e*, at *p*H 9.50.

We attempted to determine the electrostatic charge of PAF by adsorption and elution experiments with negatively charged particles, such as diatomaceous earth (DE) and carboxymethylcellulose (CMC) (Fig. 1). PAF in 80% ethanol at *p*H 6.5 was incubated with DE or CMC. PAF activity disappeared from the solutions. DE and CMC were washed once with 80% ethanol at *p*H 6.5, then the *p*H was gradually raised to *p*H 11. Elution of PAF was obtained at a *p*H between 9.2 and 9.7 with a maximum most frequently obtained at *p*H 9.5. The same experiment was performed in distilled water at *p*H 6.5 with similar results but very low yield of eluted PAF. These results are compatible with a PAF isoelectric point between *p*H 9 and 10. Controls for this experiment were: first, binding of arginine by DE or CMC in 80% ethanol, showing that the particles were charged in this medium; second, a lack of binding of PAF and arginine at neutral *p*H by DEAE-cellulose, a positively charged particle; and third, binding of aspartic acid in 80% ethanol by DEAE-cellulose but not by DE or CMC. Experiments were undertaken to obtain release of PAF from rabbit basophils without antigen–IgE interaction. Overnight slow agitation of leukocyte preparation from immunised or normal rabbits in TTBSA (*p*H 7.4) at 22° C released small amounts of a PAF-like material (spontaneous release (SR)). In keeping with the basic nature of the molecule, it was postulated that a better release would be obtained at a *p*H where the molecule has a neutral electrostatic charge. Indeed, SR was

obtained readily at a starting *p*H of 10.5 (final *p*H 9.5) within 90 min at 22° C. Through the whole procedure of purification, the molecule obtained by spontaneous release at *p*H 9.5 showed exactly the same characteristics as PAF actively released at *p*H 7.4. At *p*H 9.5, no metabolic activity of the cells was necessary for PAF release—in contrast with the metabolic activity required for release at *p*H 7.4 (J. Benveniste, unpublished). Human leukocytes were prepared by sedimentation of blood in 2.5% gelatin in PBS, followed by osmotic shock and several washings with TTBSA. Final leukocyte preparations contained 0.2–1% basophils with other leukocytes in normal proportion. Incubation of leukocytes in TTBSA at 22° C gave exactly the same results as in rabbits, that is, small amounts of a PAF-like factor at *p*H 7.4 and much higher amounts, comparable to those obtained from rabbit leukocytes, at *p*H 10.6. This human factor bound to BSA, was soluble in 80% ethanol, showed neutral electrostatic charge at *p*H 9.5 and an apparent molecular weight of 1,100. Further purification and identification of the molecule is under way in our laboratory.

These results indicate that PAF is a basic molecule with a molecular weight of 1,100. Its highly positive charge at physiological *p*H could explain its tendency to bind to negatively charged surfaces. It is likely that the molecule also possesses hydrophobic sites responsible for its binding to BSA and plastic walls in aqueous but not in 80% ethanol solution. PAF represents a new mediator of anaphylaxis, different from those already described: histamine, SRS-A (ref. 7) and ECF-A (refs 8 and 9). In rabbits, PAF has been clearly identified as of basophil origin: we have obtained the release of PAF by anti-IgE antiserum but not anti-IgG (ref. 6). It has been implicated in immune complex deposition through its aggregating and releasing action on platelets. The identity of the factors obtained from human leukocytes and from rabbit basophils makes the basophil a likely source in the human. Preliminary results in our laboratory show that leukocytes from patients having undergone basophil degranulation during anaphylactic shock do not release PAF, a situation very close to immunised rabbits injected daily with small doses of antigen. The direct evidence of the basophil origin of human PAF remains to be demonstrated, however. If the existence of PAF is firmly established in the human, it could represent, according to the experimental model, the mediator of a mechanism involving IgE-sensitised basophils in the pathogenesis of immune complex deposition. This mechanism would be a link between immediate hypersensitivity and immunological diseases associated with severe structural injury.

Organochlorine residues, eggshell thinning and hatching success in British sparrowhawks

SPARROWHAWKS (*Accipiter nisus*) in Britain have laid thin-shelled eggs throughout the period of DDT usage[1], and in several predatory species in North America an inverse correlation has been shown between shell thickness and DDE levels in eggs, both in natural and in experimental situations[2-4]. It has been claimed that eggshell thinning is associated with reduced hatching success, and that both effects could be implicated in a sequence leading to population decline. We have examined these relationships up to hatching stage in the sparrowhawk in Dumfriesshire, southern Scotland, where it still breeds in good numbers. During 1971–73 full details were obtained from 325 nests, and eggs from 130 clutches were collected for analysis.

Egg contents were homogenised; a 5 g aliquot was mixed with anhydrous sodium sulphate and sand, and extracted overnight in a soxhlet with hexane:acetone 2:1. The extract was evaporated to dryness in a tared beaker and total lipid estimated. The extract was then reconstituted in 25 ml hexane, and 5 ml was cleaned up by florisil column chromatography. (Liquid-liquid partitioning of the extract to remove fat was found to be unnecessary.) A further 5 ml aliquot was used for a duplicate estimate of lipid content. Hexane and hexane/ether chromatography fractions were used directly for analysis, using standard gas chromatography methods on columns packed with SE 30, SE 30-OV 210, and GE-XE 60 (after Richardson[5]). Results are given as parts per million (p.p.m.) in lipid, as the most valid basis for expressing organochlorine residues in eggs. On average, fresh sparrowhawk eggs contain approximately 6% by weight of lipid, so results can be converted to a wet weight basis by dividing them by 17.

The main residues found were DDE (the principal metabolite of DDT), polychlorinated biphenyls (PCB) and dieldrin (Table 1). Only results from eggs with embryos less than half grown were included. By this stage only a small reduction in lipid content (< 10%) and negligible removal of calcium from the shell has occurred[6]. When eggs from the same clutch, but at different stages of development, were analysed, no evidence was found that residues were metabolised, as proposed by Hazeltine[7]. Residues remained in the same relative proportions, and the increase in concentration in lipid during development was of the extent predicted from the amount of lipid metabolised.

Table 1 Organochlorine content and shell indices of sparrowhawk eggs from southern Scotland 1971-73

	Mean + s.e. (p.p.m. in lipid)	
DDE	148 ± 8	(n = 131)
PCB	66 ± 4	(n = 131)
Dieldrin	26 ± 1	(n = 131)
Total organochlorine	240 ± 11	(n = 131)
Shell index	1.17 ± 0.01	(n = 122)

Numbers refer to clutches. Each clutch represented once only by mean values and shell indices calculated by Ratcliffe's method[1].

Compared with 71 clutches collected in the same general area in 1900-45, which had a mean shell index of 1.43 ± 0.01, those collected in 1971-73 showed an 18% reduction in shell index ($P < 0.001$). This is of the same order as that found for a wider part of Britain by Ratcliffe[1]. Using all recent eggs, with each clutch represented only once by mean values, eggshell index was inversely correlated with the logarithm of DDE concentration (index = 1.568 − 0.186 ($\log_{10}$ DDE), $r = -0.359$, $P < 0.001$). It was also inversely correlated with $\log_{10}$ PCB concentration, though less well ($r = -0.231$, $P < 0.01$), and only poorly correlated with dieldrin concentration ($r = -0.101$, not significant). The correlation of PCB with shell thinning

in our eggs was probably because PCB was itself correlated with DDE ($r=0.480$, $P<0.001$). Lincer[8], however, has shown that, while PCB had no direct effect on shell thinning in captive American kestrels, it potentiated the effect of DDE.

Among 325 study nests, 110 (34%) showed 'normal' hatching success, 101 (31%) showed partial success, and 114 (35%) failed completely. Success was classed as 'normal' if all eggs hatched, or if no more than one egg was addled (watery), and there were no egg breakages and no 'dead-in-shell' embryos. This criterion was established from extensive hatching data collected in Britain before 1946 (ref. 9). The hatching success of these various recent clutches was inversely related to their organochlorine content (Table 2).

Table 2 Hatching success and shell indices in relation to organochlorine content

Success	*n*	Total organochlorine content (mean ± s.e.)	*n*	Shell index
1. Normal*	17	157 ± 13	15	1.27 ± 0.03
2. Partial†	74	226 ± 11	70	1.20 ± 0.01
3. Nil	40	293 ± 25	37	1.11 ± 0.02

Each clutch represented once only by mean values; shell indices calculated by Ratcliffe's method[1].

* No more than one egg addled, no breakage and no 'dead-in-shell' embryos.

† One or more eggs broken or 'dead-in-shell' embryos but at least one young hatched.

The main cause of unsuccessful breeding was failure to lay (having built a nest). This occurred at 49 (15%) of 325 nests, and accounted for 43% of all complete failures. It was apparently not recorded in British sparrowhawks before 1946 (ref. 9). Egg breakage was the second commonest cause of failure, the 35 instances accounting for 11% of all clutches and 31% of all failures. Breakage was in general related to the degree of shell thinning (Table 3), but the facts that eggs in 22% of clutches with normal shell indices were broken, whereas eggs in 66% of those with low indices survived, imply that some other factor, such as parental care, was also involved. Usually the eggs in a clutch were broken individually over several days, until only one remained, which was then deserted. Analyses

Table 3 Incidence of egg breakage* in clutches with different shell indices

Shell index	0.80–1.00	1.01–1.20	1.21–1.40	1.41–1.60
No. of clutches	9	52	57	3
No. with breakage	7	20	12	1

* One or more eggs broken; clutches deserted fresh excluded.

of those remaining eggs from clutches gave organochlorine levels of 350 ± 47 p.p.m. The third commonest cause of failure was desertion, which occurred at 5% of all nests and accounted for 15% of all failures. The 16 clutches involved showed a wide range of organochlorine contents, with a mean of 200 ± 23 p.p.m., lower than that in other types of complete failure. The remaining 13 clutches were unproductive because the eggs, though incubated and undamaged, failed to hatch. This involved 4% of all nests, and 11% of all failures. Such failures might have been due to poor parental care, impaired gas and water exchange through a thin shell or a direct toxic effect of high residue levels. Embryo deaths from thin shells alone seems unlikely, as the 10 clutches involved had by no means the thinnest shells (mean 1.15 ± 0.01), but by far the highest organochlorine levels (mean 363 ± 19 p.p.m.). Among nests which produced at least one young, unhatched eggs were found in 51 (19% of all nests), broken eggs in 27 (8% of all nests), and both unhatched and broken eggs in another 23 (7% or all nests). Once the eggs hatched, survival of young in all groups of nests was greater than 90%.

In conclusion, in spite of widespread shell thinning, egg breakage was a less important cause of unsuccessful breeding than failure to lay (having built a nest), while desertions and embryo deaths also accounted for a large proportion of failures in clutches. Clutches failing in all these ways, except desertions, showed organochlorine levels significantly higher than those showing normal success.

We would like to thank D. A. Ratcliffe and D. Jenkins for their comments on the manuscript.

Species diversity in temperate and tropical Ichneumonidae

One of the axioms of ecology is that the diversity of species is greater at low than at high latitudes. This was appreciated by Alfred Russell Wallace more than a century ago and has been repeatedly demonstrated in the more conspicuous groups of organisms such as trees, birds, and butterflies. Ecologists have produced a variety of theories, none entirely satisfactory, to explain latitudinal gradients in diversity, but an understanding of the phenomenon remains as elusive today as in Wallace's time.

Here we report an apparent exception to the rule in a family of parasitic Hymenoptera, the Ichneumonidae, which are mostly small, wasp-like insects. There are, however, more species of Ichneumonidae than of vertebrates, and in few groups of animals can there remain so many undescribed species. Virtually all ichneumonids are parasitic on the larvae and pupae of insects with a complete metamorphosis, especially Lepidoptera, Diptera, Neuroptera, Coleoptera, and Symphyta. The dependence of ichneumonids on herbivorous insects indicates that they have an enormous potential, as yet hardly explored, for programmes of biological control of pests.

Ichneumonids are abundant wherever there is vegetation and where it is not too dry, but few species are common. We have obtained large samples of them from three gardens: at Kampala in Uganda, Freetown in Sierra Leone, and Leicester in England. We have available another sample collected in Skåne, southern Sweden, not from a garden, but from disturbed land along a small stream. All four samples were collected in Malaise traps[1], tent-like constructions into which flying insects wander to fall eventually into a bottle of alcohol attached to the top of the trap. Malaise traps employ neither bait nor light and do not therefore attract insects, although undoubtedly some insects are more likely to be caught than others because of their behaviour. The only assumption we have made in our calculations of species diversity is that the traps do not select for either common or rare species.

The three gardens are not of course ecologically identical—Kampala and Freetown are on opposite sides of tropical Africa; the garden at Leicester is in the suburbs of a large city—nevertheless they share features common to all gardens: an abundance of flowers, and a wide variety of plants and trees introduced from other parts of the world. The Skåne sample should perhaps be considered separately and is added only to provide further evidence of the pattern of species diversity discovered.

Results of an analysis of the four samples are given in Table 1. The traps were operated day and night in all weather, and the sampling period in each locality included all months in which insects are flying. The differences in sample size shown in Table 1 do not necessarily reflect differences in abundance; much depends on the habitat and the efficacy of the traps in different situations, but we have the impression that, as a group, ichneumonids are rather more abundant in the temperate than in the tropical localities. The number of species recorded in each of the four samples is astonishing; the figure of 326 species in the Leicester garden represents about 16% of the species on the British list[2].

The information theory index of diversity[3], H, enables an overall comparison of the four samples. The values of H for Freetown and Leicester are not significantly different but all other paired samples are different from each other at the 1% level. The value of H is significantly smaller for the Kampala than for the Leicester and Skåne samples and is smaller for the Freetown than for the Skåne sample.

The massive species diversity in the Ichneumonidae is further reflected in Table 1 by the calculation of the number of species taken once only and the percentage of the commonest species in each of the four samples. A quite extraordinary number of species was found once only and no species is really common.

Table 1 Two tropical and two temperate samples of Ichneumonidae compared

	Sample size	Species	Diversity index, H, and s.e.	Species taken once	% commonest species
Kampala	2,268	293	4.524±0.032	116	10.1
Freetown	1,979	319	4.934±0.029	117	4.9
Leicester	2,495	326	4.937±0.024	122	3.2
Skåne	10,994	758	5.481±0.014	203	5.5

There is no evidence of the expected greater diversity in the two tropical localities. A large (but for the tropical species, unknown) proportion of the species of ichneumonid parasitise Lepidoptera caterpillars. There is no doubt about the greater diversity of Lepidoptera in the tropics. We estimate that there are 300 species of butterflies in the Freetown garden[4] but have found only 15 species in the Leicester garden. Butterflies comprise only a small fraction of the total species of Lepidoptera but probably reflect the situation in the remainder. The explanation of the high diversities in both the tropical and the temperate samples is probably associated with the fact that each species of ichneumonid tends to be niche specific rather than host specific[5]. In the parasite-host relationships considered here there may be no more niches in the tropics than in the temperate region, in contrast to the situation that probably prevails for most other feeding relationships.

We suggest on the basis of these samples that the Ichneumonidae are an exception to the rule that species diversity decreases from the equator to the poles, and that this single, little known family of insects can produce, even within a small area, a variety of species unparalleled in any other family of organisms. The Leicester sample is from an ordinary suburban garden. The trap sampled insects flying below 1.1 m over an area of only 2.6 m^2 and yet in one season produced 326 species, seven times as many as have been recorded in Monks Wood National Nature Reserve[6]. Both tropical samples contain many species and some genera new to science[7] and the entire collection has been given to the American Entomological Institute.

We thank Drs Henry and Marjorie Townes of the American Entomological Institute for tabulating the species. We also thank D. O. Chanter for computing the diversity values and Bo Svensson for operating the Malaise traps in Sweden.

Role of antennae of the dragonfly *Orthetrum cancellatum* in flight control

The function of the antennae of insects as air current sense organs and their relationship to flight control has already been investigated by behavioural studies in flies, bees and locusts[1–6], all of which are excellent fliers. The dragonfly is also an excellent flier although it possesses a very different flight apparatus[7–9]. Even though flight is apparently influenced by the eyes and the neck sense organs of the dragonfly[10,11], it seems unlikely that these organs have anything to do with the control of movements which are dependent on the surrounding air for their stimulation. For the measurement of flying speed relative to the surrounding air, for example, one might expect that, just as in the other insects, the antennae play an important and specific role. It is this hypothesis which has been tested in the present work, the results of which are reported below.

Experiments were carried out on the dragonfly *Orthetrum cancellatum L.* (Anisoptera, Odonata) 2–6 d after the imaginal moulting of larvae, which had been collected from various ponds in the area. For the flight experiments the foremost dorsal part of the mesepisterna of the animal was firmly fixed to a rod by the application of rosin wax. The wing-stroke angles, φ (Fig. 2*a*) of the fore and hindwings of the animal flying tethered in front of a wind tunnel were measured from photos (red light; exposure time, 1 s) which were taken just after the start of flight. The optical axis of the camera was perpendicular to the wing-stroke plane which formed an angle of about 45° with the vertical. The room temperature was 29° C. Control measurements at the end of each experiment showed that the animals were not noticeably exhausted.

The two antennae of the dragonfly are relatively small and are located in the antennal sockets between the frons, the vertex and the compound eyes (Fig. 1). Each antenna is composed of the basal small conical scapus, the somewhat elongated cylindrical pedicellus and the distal bristle-like flagellum pointing frontally, upwards and laterally. It is the scapus–pedicellus joint which is primarily responsible for active movements of the antenna even though passive

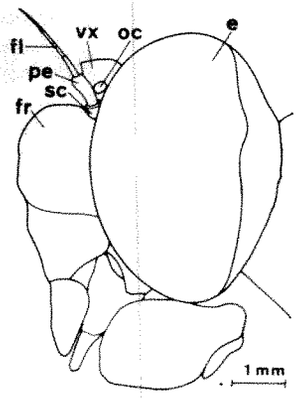

Fig. 1 Lateral view of the head of *Orthetrum cancellatum* (♀). The antenna consists of the scapus (sc), pedicellus (pe) and flagellum (fl). e, Eye; fr, frons; oc, ocellus; vx, vertex.

movements can be effected by external forces in the joints between the four flagellar segments as well as in the pedicellus–flagellum joint. For example, during flight, the flagellum is bent backwards at these joints by the impact pressure from the frontal air current. It is possible that it is this movement which stimulates mechanoreceptors situated at these joints (for example, Johnston's organ located in the pedicellus) and which consequently may allow the dragonfly to register its flight speed relative to the surrounding air, as already shown in other insects[1–6]. To test this hypothesis, the flight behaviour of normal insects and insects without flagellae was compared, using the total wing-stroke angles (φ_t) of the fore and hindwings as behavioural flight parameters. The dorsal (φ_d) and ventral components (φ_v) of the wing-stroke angles were also evaluated as shown in the insert of Fig. 2*a* ($\varphi_t = \varphi_d + \varphi_v$).

In normal animals, the total wing-stroke angles (φ_t) of the fore and hindwings in the absence of air currents are approximately of the same value (Fig. 2*a* and *d*). These wing-stroke angles (φ_t) are reduced equally in both pairs of wings as air speed increases (Fig. 2*a*: *n*; $\triangle\varphi_{t0-4}=48°$. Fig. 2*d*: *n*; $\triangle\varphi_{t0-4}=40°$. $P=0.18$). This decrease depends only on the reduction of the dorsal component (φ_d; Fig. 2*b*, *e*: *n*) since the ventral component (φ_v) is nearly independent of the air speed (forewing: Fig. 2*c*: *n*, $\triangle\varphi_{v0-4}=8°$; $P=0.08$. Hindwing: Fig. 2*f*: *n*; $\triangle\varphi_{v0-4}=7°$; $P=0.045$).

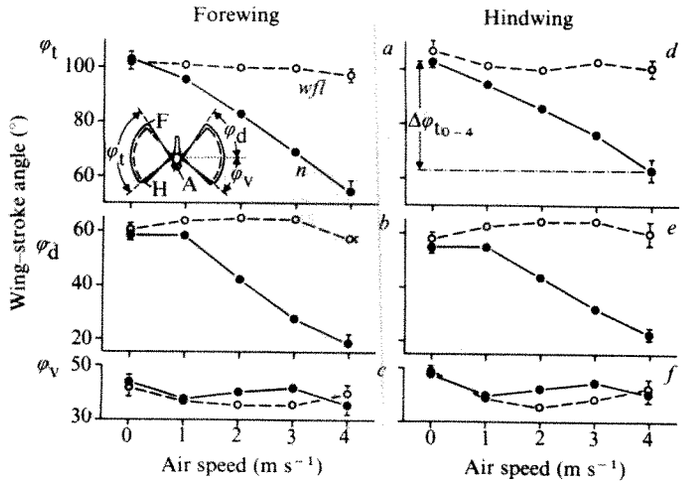

Fig. 2 *a–f*, Dependence of the wing-stroke angle (φ) on the air speed of a wind tunnel. Each point represents the mean of 70–110 measurements from 11 females and 8 males. Vertical bars indicate the standard error (± s.e.). A, antenna; F, forewing; H, Hindwing; *n*, normal animals; *wfl*, animals without flagellae: φ_t, total wing-stroke angle; φ_d (φ_v), dorsal (ventral) component of the wing-stroke angle; $\triangle\varphi_{t0-4}$, difference between the wing-stroke angle without air current (0) and with frontal air current with a speed of 4 m s^{-1} (ref. 4).

On the contrary, in insects whose flagellae had been cut off at their base 30 min or more before the experiments, the decrease of the wing-stroke angles of the forewings with increasing air speed ($\triangle\varphi_{t0-4}=7°$; Fig. 2*a*: *wfl*) is much smaller than in normal insects ($\triangle\varphi_{t0-4}=48°$; Fig. 2*a*: *n*; $P<0.0002$). This is also true for the wing-stroke angles of the hindwings (Fig. 2*d*: *wfl*, $\triangle\varphi_{t0-4}=6°$; *n*, $\triangle\varphi_{t0-4}=40°$, $P<0.0002$).

It seems, then, that the different flight behaviour of normal insects and those without flagellae is reflected by the distinct change in the dorsal component of the wing-stroke angle (φ_d). More specifically, the decrease in dorsal component (φ_d) as a function of increasing air speed is much reduced in both the forewing (Fig. 2*b*; $P<0.0002$) and the hindwing (Fig. 2*e*; $P<0.0002$) of dragonflies without flagellae. The ventral component (φ_v) of both wing pairs, however, is independent of the air speed both in animals without flagellae and normal animals (Fig. 2*c*, *f*).

The results indicate that some mechanoreceptors in the antennae, stimulated during flight by the action of air currents on the flagellae, are responsible for relaying information about the air speed necessary for the control of wing movements. These receptors, however, affect only the dorsal wing-stroke angle, the ventral components of both wings functioning independently of the surrounding air. That means that the antennae of dragonflies may be air-current sense organs which control flight performance, probably the flying speed, a finding which is consistent with those previously reported for other insects[1–6].

Evidence for a gene-specific RNA determining resistance in wheat to stem rust

Although the inheritance of resistance[1] in wheat (*Triticum aestivum* L.) to stem rust (*Puccinia graminis* Pers. f. sp. *tritici* Eriks. & E. Henn.) is fairly well understood, most efforts to elucidate the biochemical mechanism involved have been unsuccessful. Biochemical studies of plant diseases involving rusts and other obligate parasites[2] have contributed to knowledge of biochemical symptomatology, but no chemical changes have been correlated with the action of specific genes for resistance. Future advances it seemed,

would depend on a reliable test to facilitate such correlations, and so we have developed a bioassay with the necessary specificity, which detects the presence of metabolites involved in the expression of the resistance. We have thus been able to demonstrate a gene-specific RNA that seems to be directly responsible for initiating the resistant reaction in wheat against stem rust. A preliminary report of some of these findings has been presented[3].

In our work with the wheat/rust system we were interested in the highly specific interactions that are consistent with the gene-for-gene hypothesis[4]. Briefly, this hypothesis states that for every gene for resistance in the host there is a specific and related gene for virulence in the parasite. Interaction between these genes may involve transfer of information across the host/parasite interface. The substances involved in this transfer must be able to carry a high informational content because many genes for resistance have already been identified. Nucleic acids, proteins and complex carbohydrates fulfil this requirement. We believed that compounds involved in the expression of resistance could best be obtained from resistant reacting tissues containing a large number of haustoria, for histological observations[5] of the resistant interaction have shown that cell necrosis, which is characteristic of resistance, is always associated with the establishment of haustoria. To obtain such tissue we exploited the temperature lability[6] of the *Sr6* gene at temperatures above 25° C. Wheat leaves containing this gene were inoculated with spores of the avirulent race C17 (56), and maintained at 26° C to suppress host cell necrosis that would normally occur in this interaction at lower temperatures. Seventy-two hours after inoculation, when the leaves were extensively colonised, plants were transferred to 20° C for a further 30 h to initiate the necrotic reaction, then collected for the preparation of extracts.

In developing a useful bioassay it was desirable to simulate natural conditions as closely as possible. Normally, in interactions involving the *Sr6* gene for resistance and the *P6* gene for avirulence, necrotic cells develop at most infection sites shortly after haustorial formation, whereas few necrotic cells are produced in susceptible interactions[5]. Our objective was to test extracts for their ability to induce the formation of similar necrotic cells in wheat leaves inoculated with a virulent race of stem rust. We defined an active extract as one that induces significantly more necrotic cells in the genotypically resistant leaves (R line) than in the genotypically susceptible leaves (S line) of wheat.

For statistical purposes, necrotic sites consisting of one or several contiguous necrotic cells were counted. If the average incidence of necrotic sites is the same in leaves of both lines, then we would expect, if we had equal numbers of observations in both cases, that half the necrotic sites would appear in the sample of the R line. This property can be used as the basis for a statistical test[7] which has certain optimal properties if the necrotic site counts follow a Poisson law. If N_R and N_S necrotic sites occur in n_R and n_S observations in leaves of the R and S lines, respectively, then we can use the properties of the binomial distribution to test if N_R necrotic sites occur in a total random sample of (N_R+N_S) necrotic sites with probability $n_R/(n_R+n_S)$ expected if the average incidence of necrotic sites is the same in leaves of both R line and S line. For $N_R+N_S > 20$, a normal approximation was used.

Preliminary experiments with crude nucleic acid preparations showed that significantly more ($P < 0.005$) necrotic sites were produced when the extract obtained from the *Sr6/P6* interaction was injected into bioassay plants of the R line (containing the *Sr6* gene), than when it was injected into plants of the S line (Fig. 1). Non-injected leaves of either line, and leaves that were injected but not infected, contained virtually no necrotic sites. The presence of necrotic sites in infected leaves of the S line suggested that the crude nucleic acid extract also contained substances which caused nonspecific necrosis in infected leaves of both lines, in addition to the component that showed specificity towards the *Sr6/p6* interaction.

Typically, crude nucleic acid extracts contained RNA, DNA and protein in a ratio of 5:4:1, by weight. Because of their high DNA content these crude extracts were viscous and difficult to inject. Treatment with cetyltrimethylammonium bromide (CTA), DNase and protease yielded preparations with higher specificity towards bioassay plants

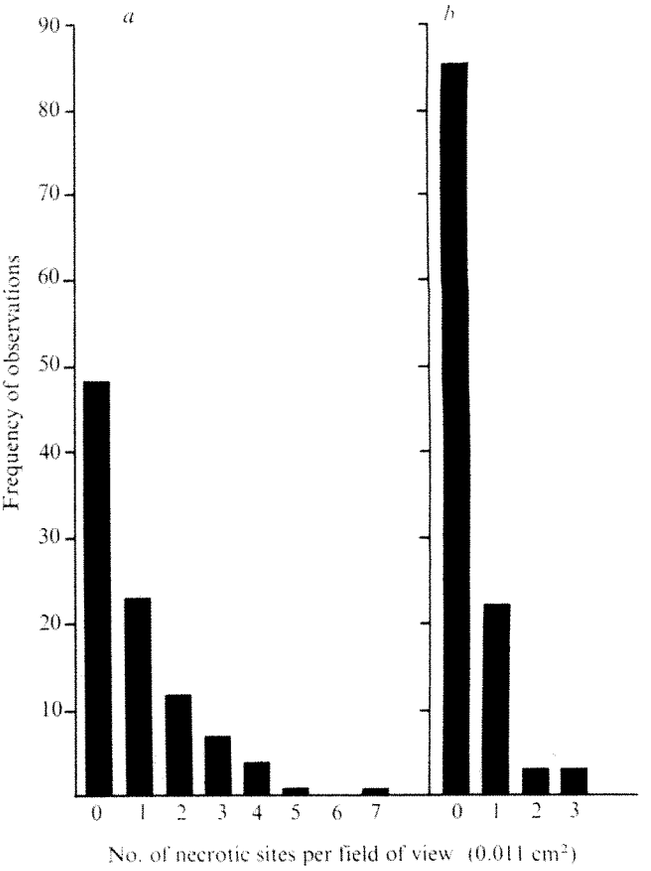

Fig. 1 Bioassay of a crude nucleic acid extract prepared from Chinese Spring wheat (containing the *Sr6* gene for resistance) infected with race C17(56) of wheat stem rust (containing the *P6* gene for avirulence). The extract was prepared[8] by homogenising plant material with *n*-butanol/chloroform/1M K_2HPO_4 (1:1:2 v/v/v), followed by deproteinisation of the aqueous phase with phenol. Nucleic acids were recovered by precipitation with ethanol and redissolved in 15 mM NaCl, 1.5 mM sodium citrate, *p*H 7.0 (1/10 SSC). Primary leaves of bioassay plants (7-d-old) were heavily infected with a virulent race (C45(56A)) to give 800–1,600 appressoria cm^{-2}. Uredospore suspensions (6 mg ml^{-1}) in 0.1% gelatin and 0.001% Tween 20 were applied with cotton swabs along 2 cm of the adaxial (upper) leaf surface, 2–3 cm from the leaf tip. Inoculated plants were incubated in the dark (16 h, 20°C) then transferred to a growth chamber (16 h 20,000 lux; 8 h darkness; 20°C). This resulted in near-synchronisation of fungal development[5]. Twenty-four hours after the beginning of the first photoperiod, extracts in 1/10 SSC were injected[9] into leaves between the tip and the inoculated area, so that the intercellular spaces in the inoculated region were flooded with extract. Six hours later the infected regions were excised, cleared and stained with Trypan blue (C.I. No. 23850) for microscopic examination[5]. Necrotic cells appeared to have collapsed and stained dark blue. They were also identified in unstained tissue by their characteristic fluorescence[10]. Resistant and susceptible near-isogenic lines of wheat produced by W. Q. Loegering[11] from chromosome substitution lines of Chinese Spring wheat were used in these studies. *a*, R line (*Sr6/p6* interaction); mean number of necrotic sites per field of view was 1.0 *b*, S line (*sr6/p6*) interaction; mean number of necrotic sites per field of view was 0.246.

Table 1 Characterisation of the active component in a crude extract from resistant reacting wheat leaves (*Sr6/P6* interaction)

Details of the preparation of the crude extract are given in the legend to Fig. 1.

RNA and DNA were determined with ethidium bromide[13] using highly polymerised calf thymus DNA (Sigma) and wheat germ RNA (Calbiochem) as standards. Protein was determined with Folin reagent[14] using bovine serum albumin as standard. Plants used for the bioassay were: for R line, Chinese Spring wheat containing the *Sr6* gene; and for S line, Chinese Spring wheat containing the *sr6* gene. Both were infected with race C45(56A) of wheat stem rust (containing the *p6* gene).

* We used 100 μg of RNase-free DNase (Worthington) and 30 A_{260} units nucleic acid ml⁻¹, 500 mM NaCl, 50 mM $MgCl_2$, 10 mM Tris-HCl (*p*H 7.4) 1 h, 20° C. After incubation the mixture was deproteinised with phenol, extracted five times with ether, and then nucleic acid precipitated with ethanol and dissolved in 1/10 SSC.

† We used 10 mg of predigested insolubilised protease (Miles) and 30 A_{260} units nucleic acid ml⁻¹, in 1/10 SSC, 1 h, 37° C. Protease was removed by centrifugation, nucleic acid precipitated with ethanol and dissolved in 1/10 SSC.

‡ We used 100 μg pancreatic RNase (Sigma), 25 units T_1 RNase (Miles) and 30 A_{260} units nucleic acid ml⁻¹, 1 h, 37° C. Enzyme was removed with phenol as described above.

§ Oligonucleotides, as determined by acrylamide gel electrophoresis.

¶ Apparent high protein content due to products from self-digestion of protease.

** *R* significantly greater than *S* at 0.05 level of probability.

of the R line (Table 1). Digestion with RNase, however, destroyed this specificity, indicating that the active component was a ribonucleic acid. CTA precipitation of the crude nucleic acid, followed by digestion with DNase, resulted in preparations containing RNA, oligonucleotides of DNA and protein in a ratio of 94 : 5 : 1, by weight. Such preparations had a low viscosity at high RNA concentrations, and could be readily injected into wheat leaves. Eight separate RNA extracts prepared in this way were tested in this bioassay system and they all caused more necrosis in plants of the R line than of the S line.

Having demonstrated that an active RNA can be obtained from the *Sr6/P6* interaction, we wished to know if active extracts could be obtained from other gene interactions, and whether active RNA isolated from one system was active in systems containing other genes. An active RNA extract obtained from the *Sr6/P6* interaction was not active in the *Sr5* bioassay system (Table 2). When a separate extract prepared from leaves of the *Sr6* R line, infected with a different race (avirulent to *Sr6*) was used, it was active in the *Sr6* bioassay system but inactive in the *Sr11* bioassay system. Conversely, an extract from leaves of the *Sr11* R line, maintained at 20° C and infected with a race avirulent to *Sr11* (*Sr11/P11* interaction), was active in the *Sr11* bioassay system but inactive in the *Sr6* bioassay system. It was not possible to obtain an active extract from the *Sr5/P5* interaction. We attributed this lack of activity to the fact that the host/parasite interaction conditioned by the *Sr5* gene is usually restricted to very few cells and permits little potential for the production of detectable amounts of an active component. Since the *Sr5* gene is not temperature sensitive, it is not possible to obtain more extensive colonisation of the leaves by growing the inoculated plants at higher temperatures.

In summary, our experiments have demonstrated that RNA is directly involved in the resistant reaction of wheat to stem rust and that the active RNA shows specificity comparable to the specificity of the host/parasite system. Our bioassay should make it possible to obtain further information on the chemical nature of the active RNA and its production, and on the mechanism of action leading to cell necrosis. We believe that this approach to the study of host/parasite interactions may be applicable to other host/parasite systems for which a gene-for-gene relationship exists.

Virus-like particles in *Leishmania* parasites

VIRUSES or virus-like particles (VLPs) have been found in *Entamoeba histolytica*[1], in the amoeboflagellate *Naegleria gruberi*[2] and in malaria parasites[3–5], but there have been no reports as yet of such organisms being found in the Trypanosomatidae. During investigations on the ultrastructure of various members of the genus *Leishmania*, however, VLPs have been found in the promastigote forms of an isolate of *Leishmania hertigi*. *Leishmania hertigi*[6] was obtained from Panama and kept in our laboratory on blood agar slopes or as cryopreserved material at the temperature of liquid nitrogen. Examination of the promastigotes of *L. hertigi* immediately revealed cytoplasmic inclusions of a type which had not been observed in any of our previous studies on the promastigotes of *Leishmania* species in culture.

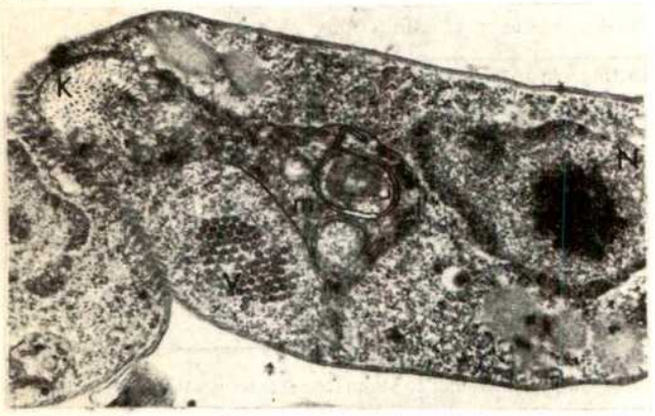

Fig. 1 Electron micrograph of section of promastigote of *L. hertigi* showing group of VLPs (V), and hollow core of some of the particles can be seen. Material from 6 d culture fixed in 3% glutaraldehyde in 0.1 M cacodylate buffer, post-fixed in 1% osmium tetroxide and embedded in Araldite. K, Kinetoplast; m, mitochondrion; N, nucleus (× 22,000).

The particles are distributed throughout the cytoplasm of the promastigotes (Figs 1 and 2), and are seen in a high proportion of sections examined under the electron microscope. It is likely therefore that all parasites of this isolate are infected. The particles have no effect on the growth pattern or division of the *Leishmania* promastigotes in culture and no apparent detrimental effect on cell structure. The promastigotes divide by longitudinal binary fission in the cultures and the particles are present in the two halves of the dividing parasite and are maintained in this way. The individual particles are usually spherical in section 55–60 nm in diameter and packed in a manner typical of virus organisation, (Figs 1, 2, and 3). There is an electron-dense outer ring and an electron-lucid core, 17–20 nm in diameter (Fig. 3). The number of particles in each group is variable.

Within the cytoplasm of parasites which are known to contain VLPs, unusual rod-like structures are found which are not usually seen in trypanosomatid cells. The presence of VLPs may induce the production of these inclusions. It is not known if *L. hertigi* acquired the VLPs in natural conditions from a sandfly vector or from the mammalian

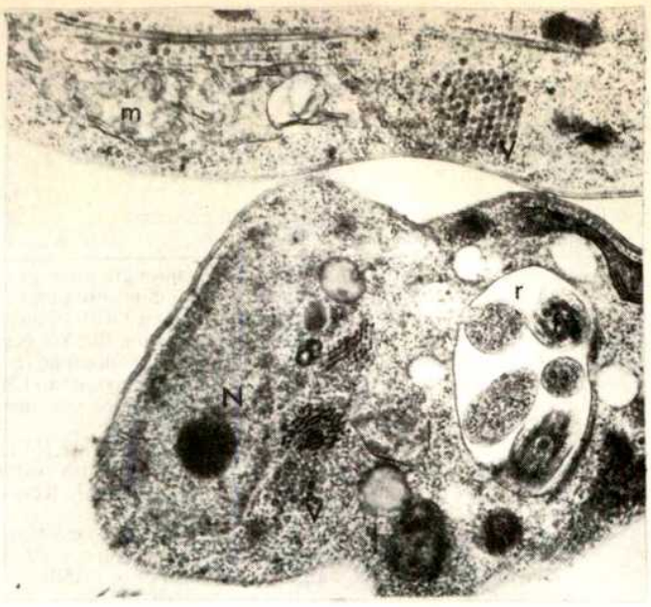

Fig. 2 Section through two promastigotes of *L. hertigi*; both parasites show VLPs (V) in their cytoplasm. Unusual cytoplasmic inclusions are present in both these parasites and may be related to the presence of VLPs. Fixation as in Fig. 1. r, Reservoir; f, flagellum (× 22,000).

host, the tropical porcupine *Coendou rothschildi*. It is unlikely the VLPs were acquired in laboratory conditions as no other *Leishmania* isolates examined have been found infected, but even if the parasites were infected in the laboratory such an observation in itself would be of great interest.

Further studies on these inclusions are in progress to characterise their nature and to determine if they are infective to other species of *Leishmania* and *Trypanosoma* and to mammalian cell cultures. The effects of any virus on the parasite genome have obvious evolutionary implications. It is also possible that intercurrent virus infections may play a hitherto unrecognised role in the clinical manifestations of *Leishmania* and *Trypanosoma* infections. Relatively few isolates have been examined with the electron microscope and such associations may be common with resulting important clinical and chemotherapeutic implications, both in treatment and possibly in transfer of drug resistance between parasites.

I thank Dr A. Herrer for supplying the isolate of *L. hertigi* and to my colleagues in the Department for support and encouragement, particularly Professor W. Peters and for the advice of Professor P. C. C. Garnham and Dr

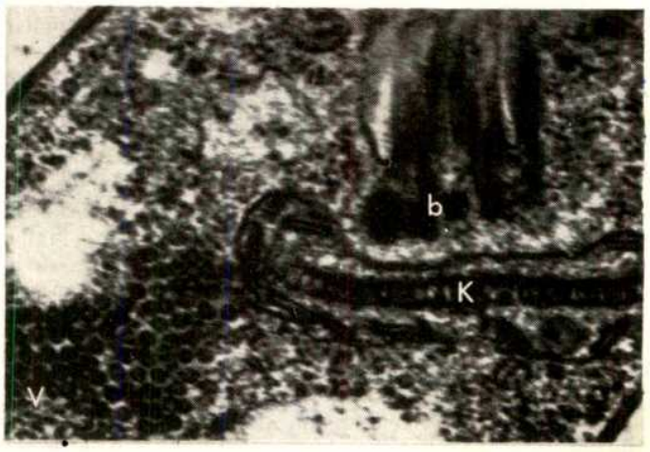

Fig. 3 Showing aggregation of VLPs adjacent to the kinetoplast (K) of *L. hertigi*. The dense outer layer and electron lucid core can be seen in some particles. Fixation as in Fig. 1. b, Basal body (× 120,000).

Devastation of a fringing coral reef by *Acanthaster*

A RECENT synopsis of reports on the status of populations of the Crown of Thorns Starfish, *Acanthaster planci* (L.), in the Indo-West Pacific[1], indicates that no extensive destruction of living corals by this starfish has yet been recorded in the western Indian Ocean. Here I present a preliminary account of an aggregated starfish population and extensive mortality of hard corals, observed in May 1973 off the north coast of Grande Comore, Comoro Islands.

Examination of a portion (about 150×300 m) of the fringing reef off Lac Salé, north-east Grande Comore (at 11° 21′S, 43° 22′E), showed an approximate 90% mortality of hard corals; this was estimated by eye at four points on the reef slope as the percentage of recently dead coral (skeletons both white and various shades of green, being in different stages of colonisation by green algae) over total coral (recently dead plus still living coral).

That the mortality was due to *Acanthaster* was inferred from the presence on the Lac Salé reef of large numbers of these starfish and from the discovery of many more at Mitsamiouli on the north-west corner of Grande Comore, where an estimated 40% of the hard corals had recently been killed. Coral predation became less frequent as I moved to the south off Mitsamiouli; my visit to Grande Comore coincided, therefore, with the recent devastation of the Lac Salé reef and the incipient devastation of the Mitsamiouli reef. The indication was that a large number of *Acanthaster* had moved as a front in an anti-clockwise direction around the northern coast of Grande Comore. Thus, the starfish that I found at Lac Salé would only have been the remnants of this mobile population. The survival of many corals in shallow water and of a small percentage of them on the reef slope, which was dominated by 'table' forms of the genus *Acropora*, rules out freshwater run off or upsurge of cold water as reasons for mortality, and further, nearly all the *Acropora* tables showed no sign of mechanical damage, although denuded of their tissue; thus changes in purely physical parameters cannot explain this mortality. A similar level of hard coral mortality due to *Acanthaster* has been observed on other badly affected coral reefs[2,3].

Hard coral colonies on the reef slope survived especially in the wider, outer parts of the surge channels which dissect the reef slope; here the coral colonies were separated from the main reef by a sandy floor, which may give partial protection from *Acanthaster*[4]. Many colonies also had been only partly denuded of their living tissue. Surviving colonies and surviving patches of partially denuded colonies are probably important in reef recovery[5].

The number of fish species recorded by sight on this reef was consistent with values for other western Indian Ocean island reefs where little or no evidence of *Acanthaster* was found (Table 1). Out of a total of 20 species of chaetodontids, which are typical 'coral fishes'[6], recorded by sight at the 3 localities, there were 13 at Lac Salé (90% hard coral mortality), 12 at Iconi (hard corals uncommon), and 12 at Mitsamiouli (40% hard coral mortality in places). Thus while *Acanthaster* and other factors can have a destructive effect on the hard coral cover, they may not affect the number of fish species. Porter[7] found that *Acanthaster* predation can have a beneficial effect on coral species diversity. Heavy stressing of Grande Comore reefs by bottom fishing and spear fishing inhibits more detailed analysis of fish faunal differences between the affected and unaffected reefs; certain species, however, such as the herbivorous acanthurids[8] *Ctenochaetus striatus* and *Acanthurus leucosternon*, may have increased on the Lac Salé reef.

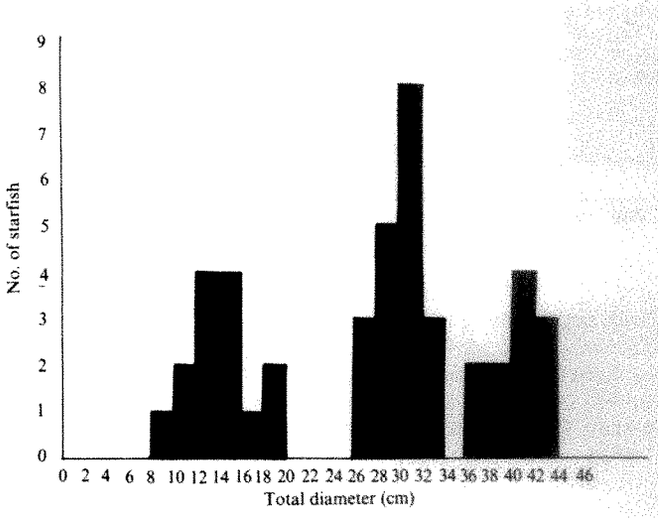

Fig. 1 Size-frequency histogram (total diameter) of 44 *Acanthaster planci* collected between 1300 and 1500 h on May 24, 1973 in the same reef flat habitat of the Lac Salé, Grande Comore, fringing reef.

Few *Acanthaster* were found in the zone of high hard coral mortality. Nearly all the individuals found were confined to the reef flat, where the coral cover was poor, but a higher proportion of the corals still survived. Conditions of swell were more marked on the reef flat than on the reef slope; starfish detached from the substrate on this reef flat had great difficulty in regaining their hold. No starfish were found in the act of feeding during the daytime, and very few individuals were visible from the sea surface. Small individuals were found only by breaking open clumps of branching corals. The size-frequency histogram (total diameter) for 44 starfish collected in the same reef flat habitat indicates the presence in the population of at least two size-classes (Fig. 1). The population may still be a mixed one, however, with animals contributed from the once-rich reef slope and from the impoverished reef flat; Dana *et al.*[9] suggested that the bimodal size distribution reported for some Sudanese Red Sea *Acanthaster*[10] might not be due to the presence of two age classes, and could have resulted from the sampling of different habitats, where coral food was more or less abundant.

H. R. Lubbock (personal communication, 1971) found large numbers of *Acanthaster* in September 1971 in Moroni harbour, Grande Comore, and from discussions with a local diver (J. Nicholas, personal communication) it seems probable that this starfish has been common on Grande Comore for even longer.

In addition to the 18 localities recorded in Table 1, I have examined nine others in the granitic Seychelles; only off Lac

Table 1 Eighteen western Indian Ocean island localities visited between April 19 and July 10, 1973

Locality	Observation time (h)	Maximum depth (m)	Fish species seen (No.)	*Acanthaster*: type and state of reef
Lac Salé, Grande Comore	3	9	104	Many starfish present; ~ 90% dead coral on reef slope. Fringing. Reef once rich.
Mitsamiouli, Grande Comore	1	13	73	Many starfish present; ~ 60% corals still living. Fringing. Reef still rich.
Iconi, Grande Comore	1	26	82	Three seen; almost no live hard corals. Fringing. Reef long 'dead'.*
Récif Vailheu, Grande Comore	1	37	85	None seen; no evidence of predation. Rich table reef.
Canzoni I., Moheli	1	26	87	None seen; no evidence of predation. Fringing. Rich coral in shallows.
Ouénéfou I., Moheli	1	19	106	None seen; no evidence of predation. Fringing. Rich coral in shallows.
Andrema I., Mayotte	4	34	154	One individual seen; no evidence of predation. Fringing. Very rich coral in shallows.
Banc du Geyser	1	28	80	None seen; no evidence of predation. Atoll. Rich coral on outer reef flat.
Banc Suzy, Nossi Bé	1	16	57	None seen; no evidence of predation. Patches.
Tsara Bajina, Mitsio Is.	2	6	97	None seen; no evidence of predation. Patches.
Behangovo, Mitsio Is.	0.5	28	43	Four seen; no evidence of predation. Rare patches on desolate slope.
Ankarea, Mitsio Is.	3	9	113	None seen; no evidence of predation. Patches.
Radam Is.	1	9	76	None seen; no evidence of predation. Patches.
Poivre, Amirante Is.	2.5	19	93	None seen; no evidence of predation. Atoll. Rich coral in places.
Alphonse, Admirante Is.	4	43	152	None seen; no evidence of predation. Atoll. Rich coral in shallows.
West North I., Cosmoledo	4	37	152	None seen; no evidence of predation. Atoll (elevated). Rich coral on outer reef flat.
Assumption	4	56	160	None seen; no evidence of predation. Elevated reef. Rich coral on outer reef flat in places.
Johnny Channel, Aldabra	1.5	9	84	None seen; no evidence of predation. Atoll (elevated). Some rich coral on channel edges.

Notes were taken underwater.
*No evidence for implication of *Acanthaster*.
Observation time is given to the nearest half hour. Also recorded are maximum depth reached, number of fish species recorded by sight and sightings of *Acanthaster*, with notes on the type and state of the reef.

Salé and Mitsamiouli, Grande Comore, have I found large numbers of *Acanthaster* and an extensive, recent mortality of hard corals. There is evidence, however, of recent population increases of *Acanthaster* elsewhere in the western Indian Ocean: on a reef off Mauritius[1], on Kenya reefs (ref. 1 and R. Tauber, personal communication) and on the 'Grand Récif' off Tuléar, Madagascar (L. A. Maugé, personal communication). It is interesting to note that de Loriol[11] reported in 1885 that specimens of *Acanthaster* were *assez fréquents* (quite common) in Mauritius.

There is no doubt that aggregations of *Acanthaster* can be responsible for extensive mortality of reef corals. Recent studies have shown that high levels of reef coral predation may be concomitant with active reef growth[12], and that in the case of patch reefs in Bermuda[13], a phase in their development is burial by sufficient particulate sediment to kill the sessile reef organisms. Aggregations of *Acanthaster* are destructive in the short term, but they may be an important factor in coral reef development in the long term[5,9,12,14,15].

I thank Nigel H. and Gwen Cornfield for their hospitality and facilities of the yacht *Marimba*. A. C. Campbell, R. S. K. Barnes, W. A. Newman, N. Holland, D. R. Stoddart, and N. V. Polunin criticised early drafts of the manuscript.

Rats learning to work for alcohol

If animals are to be used in the study of alcoholism, it is important that they show characteristics similar to human alcoholics. It has been demonstrated that animals can show tolerance and withdrawal symptoms to alcohol[1]: therefore, animals can legitimately be used to study these aspects. There has, however, been little evidence that animals develop the most important factor in alcoholism, a strong motivation to obtain alcohol for drinking. As there have been no demonstrations of animals learning a new response, or even continuing to make a previously learned response, to obtain drinking alcohol, in the presence of food and water *ad libitum*, it has been possible to claim that their alcohol consumption is 'accidental and inadvertent'[2]. If this were true, experiments on voluntary alcohol drinking by animals would be of little value for generalising to humans.

It therefore seemed critical to determine if animals could learn to work for drinking alcohol and to assess their motivation, if any, for alcohol. Animals which had developed a strong preference for alcohol in a free-choice situation were thought to be most likely to be motivated to obtain alcohol. Therefore, 60 male albino rats of three different strains were given at least 55 d free access to a 10% (v/v) ethanol solution, tap water and the standard Alko rat food. From these, six were selected for testing in the Skinner box because of their consistent high preferences for alcohol. Three were of the AA strain developed for high alcohol consumption[3,4], two were Sprague-Dawleys, and one was of the ANA strain[3,4]. During the week before testing, their ratios of ethanol solution to total fluid consumption ranged from 0.60 to 0.98.

These rats were then each housed continually in a standard two-bar Lafayette operant conditioning cage, modified

so that pressing one bar yielded a drop of about 0.1 ml of 10% alcohol solution, and pressing the other bar produced a similar drop of water. An open jar of food and a bottle of water were also available *ad libitum* at all times in the Skinner box. A 10 h dark, 14 h light illumination schedule was used.

On the first day of testing, before each rat was placed in the Skinner box, drops of water were placed on the water bar, and alcohol solution on the alcohol bar. No other shaping of any kind was used. A rat was arbitrarily considered to have learned to work for alcohol if it responded more than 100 times d^{-1} for alcohol and at the same time pressed at least twice as often for alcohol as for water.

All six rats met this criterion, four during the first night, one on the second night and one on the third night in the Skinner box. Once a rat had learned to work for alcohol, it continued to meet the criterion every day thereafter (Fig. 1.)

Subsequently, a reversal test was made by interchanging the positions of the alcohol and water bars. All but one of the animals learned the reversal: two during the first night, two on the second night, and one on the fourth night.

Two ANA rats which had not developed alcohol preferences[3,4] were also selected from the original 60 animals for testing as controls in the Skinner box, using the same procedure as before. Neither rat met the criterion during 10 d of testing. One ignored both bars and obtained its fluid from the free water bottle. The other pressed both bars about 50 times per night, but still got most of its liquid from the free water bottle.

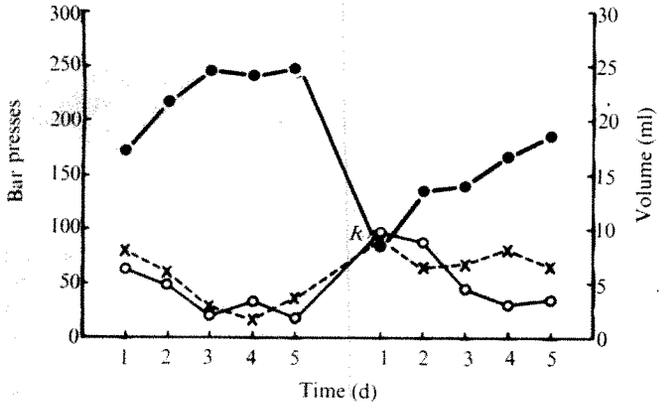

Fig. 1 Mean daily responding for 10% (v/v) ethanol solution (●) and for earned water (○) by six rats. As each bar press produced about 0.1 ml, the approximate volumes earned can be read from the ordinate on the right. Consumption of 'free water' (X) from a bottle available *ad libitum*, is also shown. After the 'reversal' (R) the alcohol and water bars were interchanged. The lower alcohol responding and higher free water intake at this time is caused by one rat that failed to learn the reversal.

The motivation for alcohol was tested in two of the rats which had previously learned to work for alcohol: one was an AA, weighing 421 g, the other a Sprague-Dawley, weighing 440 g. Weights were added progressively each day to the back of the alcohol bar, thus increasing the effort required to press it. On a continual reinforcement schedule, such as used here, this procedure should successfully measure motivation, since it has been found that rats otherwise prefer a bar requiring less effort to press[5]. This method was chosen rather than, for instance, electrifying the alcohol bar, because it should be less likely to produce confounding stressful effects.

Both rats continued pressing the alcohol bar until over 140 g were attached to it. The AA rat responded at a relatively constant rate until 137 g were attached, but showed a sharp decrease when additional effort was required. Responding by the Sprague-Dawley decreased continually throughout the experiment as a nearly linear function of the weight attached to the alcohol bar (Fig. 2).

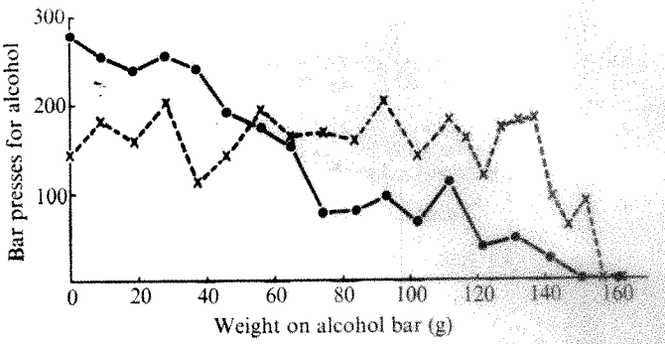

Fig. 2 Daily responses for 10% alcohol solution by rats SD15 (●) and AA141 (X), as a function of the effort required to press the alcohol bar. Each day progressively larger amounts of weight were attached to the alcohol bar, at a distance from the fulcrum equal to that of the portion upon which the rats pressed. Free food and water, and a bar, without weights, producing water, were continually available.

Unlike previous studies, in which rats have bar pressed for alcohol[6–10], the present findings clearly cannot be attributed to motivation from hunger or thirst, as food and water were concomitantly available *ad libitum*. The inclusion of a bar producing water controls for spontaneous bar pressing or responding motivated by stimulus change or mastery. The reversal task controls for position preference. Since no shaping was used, the results are not a function of the skill of the experimenter in shaping procedures. Thus it seems that the learning was reinforced by obtaining alcohol *per se* to drink.

Some animals have previously been found to work for intragastric or intravenous injections of alcohol, and in a few cases to learn new responses for the alcohol injections[11–14]. These results showed that alcohol could be a reinforcer, but they could not eliminate the possibility that the animal's motivation for alcohol injections was somehow different from the alcoholic's motivation for a drink of alcohol. As the present study shows that animals will also learn to work for drinking alcohol, it is less likely that a fundamental difference exists between the motivations of humans and these animals for alcohol.

From a comparison with two unsuccessful (and unpublished) previous attempts to train rats to work for alcohol, it seems likely that the present procedure was successful because, first, rats were used that had demonstrated long-standing, consistent, strong preference for the alcohol solution; second, the animals remained in the Skinner box during the night, which is when rats normally drink alcohol[15], rather than being tested only in daytime sessions; and third, they had not previously been taught to bar press for water, a procedure which in one of the unsuccessful previous attempts seemed to produce a subsequent decrease in voluntary alcohol drinking.

In conclusion, humans are not the only creature sometimes motivated to obtain alcohol for drinking: some rats seem to develop a similar motivation which can lead them to learn new responses for alcohol reinforcement and to expend rather large amounts of effort to obtain it. These findings also suggest the possibility of opening many questions concerning alcohol drinking by animals to sophisticated analysis with the use of operant techniques.

I thank K. Eriksson, O. Forsander and K. Lindros for their help and advice, and P. Neuenschwander for modification of the Skinner box.

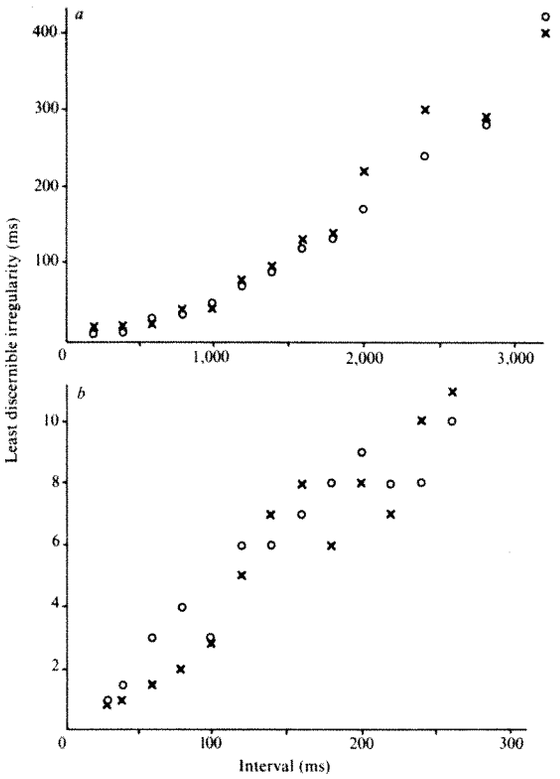

Fig. 1 The accuracy with which rhythm can be heard, or brief times assessed, plotted as least discernible deviation from regularity of a metronome, of which every fourth beat interval between beats. *a*, Intervals 260–3,200 ms; *b*, intervals 30–260 ms. Two runs are shown by the same operator on is controllably irregular, against overall tempo shown as different days. Considerable practice is needed to obtain results as consistent as these. ○, first run; ×, second run.

GENERAL

Time as heard in speech and music

THE time intervals of consequence in music range from about 50 ms, the fastest that notes may be separately fingered on the piano, to about 1 s, the tempo of slow largo. Poetry is customarily recited with beats every 600–800 ms, and the semi-isochronous stresses of speech rhythm are, according to Classe, of the order of 600 ms apart[1]. We take pride in the accuracy with which we can produce and appreciate these intervals or deviate from them at will. That we require an auditory information storage of brief duration, briefer than that customarily named short-term memory, is known, Neisser calling it echoic memory[2]; but, as distinct from our other kinds of memory which memorise events in rank order of occurrence only, what our talent for music and speech shows is that in this brief storage we possess, with a working range of a second or so, a comprehension of those things we have just heard, arranged quite accurately in true time relationship.

This was explored by devising an electronic metronome in which every fourth beat was irregular by a controllable amount, the overall tempo or interval being also under control. It was set up connected to a loudspeaker in a studio with good listening conditions, and to a timer. The interval is first set to the required figure and the irregularity to zero, using the timer. The timer dial is then obscured, and the operator's task is to increase the irregularity himself until it becomes just evident to his ear. He may repeat until satisfied. Subdividing the intervals either overtly (by foot-tapping) or covertly (for which the operator's integrity must be relied on) is barred. This least discernible irregularity is then read from the timer.

A plot of two sequences of readings for various intervals obtained by the author after several weeks' practice is shown in Fig. 1. Similar plots obtained by other operators indicate that the limit of discrimination is biologically imposed. The experiment is difficult to perform but the effect of practice is to improve the consistency of results, not the discrimination under test.

The form of the plot is striking. There are no periodicities as might be expected from cyclic brain timing mechanisms, suggested by Lenneberg[3]. In fact the approximately exponential shape indicates that the brain mechanism involved in timing partakes of the nature of a simple analogue device, possibly of a decay time or delay line type.

I suggest that the above named arrangement of events in true time relationship occurs within this mechanism, displayed as it were against an exponentially decaying scale of the 3 s or so preceding the present instant; and that this, being man's only such arrangement, provides, in effect, our sensation of time.

matters arising

'Spatial oscillations' in the Zhabotinskii reaction

SIR,—In a recent study of temperature effects and the Zhabotinskii reaction, Thoenes[1] measured the speed of the reaction wave fronts and related it to the temperature distribution in the sample. A temperature gradient was artificially imposed from outside the system.

Thoenes' interpretation of the data is, however, either unclear or misleading on some points.

In the first paragraph Thoenes indicates that the theoretical analysis which he uses was suggested by Beck and Váradi[2]. It seems more probable, however, that the reference should be to Zaikin and Zhabotinskii[3]. These authors refer to the work of Prigogine and Nicolis[4], among others, as providing the theoretical foundation for their simplified analyses. Thoenes' implication that his theoretical analysis is independent of the work of Prigogine and coworkers is therefore misleading.

This analysis rests on the assumption that the frequency of the oscillations, ω, can be described as a function of the position, x:

$$\omega(x) = \omega^0 F(x) \qquad (1)$$

This is Thoenes' equation (1). He later identifies $F(x)$ with

$$\exp(-E/RT(x)) \qquad (2)$$

where E is an energy and $T(x)$ is the position dependent temperature. This is Thoenes' equation (5). Thoenes states that this treatment explains all the phenomena reported by Zaikin and Zhabotinskii[3]. This is not surprising as they had already shown this to be true. (In this context, recent work by Winfree[5] is also interesting.)

But equation (1) can also be misleading in the context in which it is given. The oscillatory behaviour which it implies is rather rare in chemical reactions and the Zhabotinskii reaction is a very special case. Several authors have discussed the the requirements for, and the characteristics of, such chemical reactions[6-8]. These works point out that equation (1) can only describe very special types of chemical reactions.

The interpretation of equation (2) may not be as simple as Thoenes suggests. The heat output and the redox potential step during the oscillations change according to the number of oscillations which have occurred[9]. Equation (2) would not therefore be expected to give a single datum, as Thoenes apparently assumes. Some of the effects of heat production in the Zhabotinskii reaction have already been noted by Busse[10], although his interpretations of some other points were incorrect[11]. The chemistry of the Zhabotinskii reaction has been discussed extensively[12,13], and there has been a theoretical study[14] of an ideal system of the type studied by Prigogine and coworkers but with heat production included. Beck and Váradi[2] also explicitly mention the effects of the container walls on the reaction characteristics.

Thoenes' statement "I conclude that spatial patterns in the Zhabotinskii reaction are not examples of dissipative structures as described by the theory of Prigogine" does not therefore seem to be correct. Thoenes' analysis is in fact based on Prigogine's work.

I conclude that Thoenes has reported very interesting experimental results on the effect of temperature on the Zhabotinskii reaction, and that in order to interpret this data he has also reformulated and enlarged upon a previous mathematical description by Zaikin and Zhabotinskii[3] which was in turn based on the theories of Prigogine and coworkers[4].

Structure of water in porous glass

SIR,—In an attempt to measure proton mobility, Roberts and Northey, used signal line broadening from steady state nuclear magnetic resonance (NMR) to study slices of sintered glass with a pore size of ~ 15 μm (ref. 1). They infer "long range modification of the water structure by sintered glass". Their conclusions do not necessarily indicate an ordering effect, and new evidence for the water–glass system casts doubt on their results[2,3].

Signal line broadening from steady state NMR has been used as an indicator of orientation effects for adsorbed systems, Interpretation of the data is, however, often ambiguous[4]. Pulse or spin echo techniques are considered more promising and have recently been applied to many systems[5], including water on porous glass[2,3].

Our results, using pulse NMR, indicate that for a specially prepared porous powdered glass at 100% relative humidity, with an average pore size of ~ 24 Å, about 80% (v/v) of the adsorbed water is motionally restricted, and the remaining 20% (v/v) is most probably bulk water[3]. As the average pore radius approaches 100 Å, the amount of motionally restricted water in the Vycor glass is reduced to below 10% (v/v), which is approximately one layer of surface-bound water about 3 Å thick (ref. 2). Thus, for very large average pore diameters, such as the 15 μm used by Roberts and Northey, with relatively small surface areas, it is probable that far less than 10% (v/v) of the occluded water is bound. In addition, because of the notoriously low sensitivity of NMR, detection of small percentages of bound water within very large percentages of bulk water is unlikely.

For the steady state NMR experiment, broadening which results from field inhomogeneities produced by the glass matrix would occur even if 100% (v/v) of the occluded water was free. Interpretation of the NMR data for adsorbed systems is far more complicated than the observation of the broadening effect[5]. For example, relaxation rates within, and exchange rates between, various environmental states (phases) critically affect the estimation

of the actual percentage of water within a particular state[6].

These limitations seriously challenge the validity of Roberts and Northey's conclusions and probably account for the discrepancy between their results and those of Belfort *et al.*, who used the preferred pulse NMR techniques.

Yours faithfully,

GEORGES BELFORT

School of Applied Science,
Hebrew University,
Jerusalem, Israel

1 Roberts, N. K., and Northey, H. L. *Nature*, **237**, 144 (1972).
2 Belfort, G., *J. Colloid Interface, Sci.* (in the press).
3 Belfort, G., *Nature phys. Sci.*, **22**, 60 (1972).
4 Kaufman, S., Stein, J., and Gibbs, J. H., *Nature*, **225**, 743 (1970).
5 Pfeifer, H., *NMR, Basic Principles and Progress*, **5**, (edit. by Dahl, P., Fleich, E., and Kosfeld, R.,) 53 (Springer Verlag, 1972).
6 Woessner, D. E., *J chem. Phys.*, **35**, 41 (1961).

DR ROBERTS REPLIES: We acknowledge that Belfort's criticism might be valid had we simply recorded the NMR spectrum of water sorbed in the sintered glass. As pointed out in our article[1], however, the spectrum was recorded after distilled water had been drawn through the porous glass membrane for 30 h—the time normally required for the determination of a diffusion coefficient by the diaphragm cell method. The initial NMR signal of the water sorbed in the sintered glass was broadened compared with that of bulk water, and it might be argued that this broadening was simply a consequence of "field inhomogeneities produced by the glass matrix."

When water was drawn through the sintered glass for 30 h, however, the NMR signal of the occluded water became still broader, and an increase in hydrodynamic resistance also occurred (see also ref. 2). This increased broadening, which amounted to approximately 8 Hz at half-height, cannot be explained by invoking field inhomogeneities.

Belfort's work on porous glass[3] does not discuss the effect of prolonged movement of water through glass pores. In this connection the observation[2] that the conductivity across a sintered glass disk immersed in dilute potassium chloride does not alter when the solution is drawn through the disk over an extended period, whereas the hydrodynamic resistance increases, suggests that the hydrodynamic resistance is not a result of obstruction of the glass pores by air bubbles or solid particles.

The purpose of our article[1] was not to argue that water in glass pores (5–15 μm diameter) is structurally modified. Rather, we argued that it becomes modified on prolonged movement through the pores, with a resultant decrease in the hydrogen ion diffusion (and most probably the diffusion of the hydroxide ion) but with no effect on the diffusion of other ions.

It would be interesting to be able to calculate the degree of broadening of the NMR signal of water which is compatible with a reduction in the value of the diffusion ratio, D/D°, of the hydrogen ion, from 1.0 to approximately 0.9. These were the values obtained respectively from the polarographic and the diaphragm cell methods.

Our recent work[4] on deuterium ion mobility in heavy water solutions of electrolytes confirms our original finding that the diaphragm cell method gives low results for the limiting diffusion coefficient of the hydrogen ion.

IQ and race

SIR,—In her recent communication Tizard[1] showed that the effects of environment on IQ are great but that racial differences are not significant. In fact, her data on children of 4.5 yr divided into those still in institutions, those returned to their natural mothers, and those adopted, show that the non-whites have a consistently higher mean score than the whites. The racial differences within each of the three environmental classes are, indeed, not significant but the probabilities may be combined, since the classes are independent, giving $P=0.04$. Taken alone, this result might not mean much, but in Tizard's other study non-white children have higher scores in each of three IQ tests than white children, the difference being significant for one test ($P=0.02$). It seems that the non-white children have higher IQs than the whites.

Unfortunately, this result is open to several interpretations, at least two of which seem probable. Non-whites may be better endowed genetically with regard to intelligence than are whites. On the other hand, however, the children tested might not have been random samples of the racial groups to which they belong: British blacks are of recent immigrant stock and probably of above average socioeconomic status in their homelands. (Tizard found no significant differences between fathers of different races in ratio of manual to nonmanual occupations but this is a crude test and, in any case, blacks will do less well than whites of similar intelligence in job competition, because of colour prejudice and educational differences.)

The question of 'nature and nurture' with regard to IQ is politically sensitive: the extremists of both left and right are seeking support for equally silly and wicked beliefs. It is, therefore, important that the scientific examination of the question should be scrupulous. I hope that these comments will help the truth to emerge, whatever it may be and to whomever it may be unpalatable.

Yours faithfully,

J. J. D. GREENWOOD

Department of Biological Sciences,
University of Dundee

1 Tizard, B., *Nature*, **247**, 316 (1974).

DR TIZARD REPLIES: Greenwood correctly states that the non-white children in our studies had consistently higher mean test scores than the white children. As I pointed out in my letter no definite conclusion can be drawn from this finding. Greenwood's suggestion that selective immigration by IQ has occurred from the West Indies is of course possible, but if true would constitute a powerful argument in favour of environmental influences on development, as it is known that the mean IQ of the school-age children of West Indian immigrants living with their families in London is significantly lower than that of white school children. An alternative 'genetic' explanation would be that West Indian immigrants who place their children in long-term care are of higher IQ than the corresponding group of white parents. 'Environmental' explanations of the finding could also be advanced; for example, small black children are often found particularly appealing and may receive more attention from their nurses.

The main argument of my letter, however, was that within each environment inter-racial differences in test scores were small, but differences in test scores which we could relate to measured aspects of the environment were large and significant.

Is the slow worm a Batesian mimic?

SIR,—Smith[1] has suggested that juvenile slow worms (*Anguis fragilis* L.), and also those adult females which retain the dark vertebral stripe, are Batesian mimics of the adder (*Vipera berus* L.). His main evidence for this view is circumstantial; parturition occurs at the same time in the two species, but is usually about one week earlier in the viviparous lizard (*Lacerta vivipara* Jacquin). Smith suggests that parturition time in the slow worm has evolved such that the species gains maximum advantage from the mimicry.

There is, however, a simpler explanation of the time of parturition. The viviparous lizard is a strictly diurnal heliotherm, maintaining a 'preferred body temperature' of about 30° C whenever solar radiation is sufficiently intense to enable it to do so[2]; it can achieve this relatively high temperature rapidly[3]. Adders, in contrast, are both diurnal and crepuscular[4], and the slow worm, as Smith admits, is a burrowing animal which is not often seen in daylight. Body temperatures of the adder are consequently variable; they do not maintain a high temperature for long periods. Slow worms do not usually maintain a preferred body temperature at all; their body temperature is nearly always near that of the ambient air (unpublished observations).

It is not surprising, therefore, that embryological development in viviparous lizards should proceed more rapidly, and it is significant in this connection that the optimum temperature for development of viviparous lizard embryos *in vitro* is 27–28° C, whereas for slow worms it is 18° C (ref. 5).

I conclude that there is no justification for regarding the slow worm as a Batesian mimic of the adder, and adduce as additional evidence the fact that neither my children nor I—two predators with very different levels of experience—ever confuse the two species in the field.

Yours faithfully,

R. A. AVERY

4 Smith, M. A., *The British Amphibians and Reptiles*, (Collins, London, 1951).
5 Maderson, P. F. A., and Bellairs, A. d'A., *Nature*, **195**, 401 (1962).

MR SMITH REPLIES:—Herpetologists have questioned my suggestion[1] that the dorsal zigzag of some female slow worms (*A. fragilis L.*) mimics that of adders (*V. berus L.*), since anyone familiar with the animals can easily distinguish them. Dr Bellairs (personal communication) notes the different behaviour of slow worms and adders when threatened, unlike other mimetic lizards[2], and Avery here suggests that the coincidence of parturition times is explained by body temperature and habits. The usual predators of slow worms are not humans, however, but are more likely to be small, colour-blind mammals which must decide quickly whether or not to attack. Thus a character associated with a previous unpleasant experience (an adder bite) may cause momentary hesitation, giving a slightly increased chance of escape and a small selective advantage.

Whether mimicry evolved in response to concurrent parturition times or *vice versa* is incidental to the increased advantage of a birth period around the peak of the adder's when gravid females are vulnerable to visual predation as they bask in the sun. Nevertheless, it is interesting that, although slow worms mate mainly in May, fertilisation does not occur until June[3] and embryonic development begins around the birth time of viviparous lizards (*L. vivipara* Jacquin), so that 'preferred body temperature' is only part of the explanation.

Thus, Batesian mimicry seems to be the best, current explanation of the dorsal zigzag pattern and its presence in some adult females only.

Silent alleles and haploid expression in deficiency mapping

SIR,—If a portion of one of the chromosomes is missing, and a primary gene product is reduced in amount, this indicates that either one locus determining this enzyme is missing or that it is ineffective due to a silent allele[1].

The evidence can be evaluated in the conventional currency used in human linkage studies, the lod, or logarithm of the odds ratio[2,3], by the following simple procedure.

We suppose that some transformation of the enzyme level is normally distributed with unit standard deviation, and is d units in the diploid state and h units in the haploid state: this may be derived from data on 'silent' alleles, on the assumption that they are completely silent, or 'non-leaky', or inferred by halving the diploid level. If the parent conveying this hypothetical silent allele has a level a units, after transformation, the likelihood that this is due to haploid expression is the ordinate of the normal curve of unit variance with mean h or $\sqrt{(1/2\pi)}\exp[-\frac{1}{2}(h-a)^2]$ while the likelihood that it is due to diploid expression is $\sqrt{(1/2\pi)}\exp[-\frac{1}{2}(d-a)^2]$; the natural logarithm of the ratio of these ordinates is $\frac{1}{2}[(d-a)^2-(h-a)^2]$; and the logarithm of this ratio, or lod, is $0.217\ [(d-a)^2-(h-a)^2]$. The antilogarithm of this is the likelihood ratio or odds ratio.

On the data of Ferguson-Smith *et al.*[1] the mother had a mean level of 124 units; the mean level for controls with the same phenotype was 119 units and, taking the conservative estimate that a silent allele would reduce activity by 40%, we have $d' = 119$, $d = 15.4$; $h' = 71.4$, $h = 11.9$; $a' = 124$, $a = 15.7$ where the transformation $x = \sqrt{(2x')}$ is used. This gives an approximately unit standard deviation on the data of Spencer *et al.*[4]. The log of the likelihood ratio, or the lod, is then $0.217\ ((a-h)^2-(a-d)^2) = 3.1$ giving an odds ratio of about 1250:1 in favour of a nonsilent allele.

Supplementary information, such as the size of the deficiency, and the frequency of silent alleles, may also be incorporated. This is most simply done by working in logarithms throughout, so that the numerical results are additive.

The failure of the sister of the propositus to show evidence of a silent allele, which she would have a 50% chance of doing if one were there, provides a further lod of log ($\frac{1}{2}$), or 0.30, favouring deficiency.

I thank Professor M. A. Ferguson-Smith for discussions.

Muscle cross-reinnervation

SIR,—In a recent communication in *Nature*, Weeds *et al.*[1] described some modifications in the subunit constituents of myosin subsequent to surgical transposition of the nerves of two functionally disparate muscles (for example, a fast-twitch, glyocolytic muscle against a slow-twitch, oxidative muscle). The evident metabolic reprogramming of the cross-reinnervated muscles led them to conclude that "It would be interesting to know if the electromyogram activity of muscles does change following cross-reinnervation" (that is, is the alien-innervated muscle activated in a fashion comparable with that of the muscle for which the nerve was normally intended?).

Obviously, few if any efforts have been made to determine the actual pattern of utilisation of cross (and self) reinnervated limb muscles. Ideally such studies require precision monitoring of electromyogram activity (by chronic indwelling electrodes) or normal and alien-innervated muscles during the repertoire of physical activities of normal and experimental animals. There are, however, several less sophisticated observations available which indicate that cross-reinnervation by functionally dissimilar nerves does lead, at least partially, to the expected changes in patterns of activity of the affected muscles. Furthermore, an exchange of functionally similar nerves apparently allows some retention of the original manner in which a muscle was utilised.

In the course of several investigations on rats, I surgically rerouted either the phrenic nerve, or hypoglossal nerve, to a denervated ipsilateral sternomastoid muscle. Several months thereafter the animals were lightly anesthetised and the function of the sternomastoid muscle was observed directly through an incision in the neck. After phrenic reinnervation the sternomastoid muscle contracted rhythmically in concert with the intact contralateral hemidiaphragm (an activity that could be enhanced by temporarily occluding the air passages). Following hypoglossal reinnervation the sternomastoid twitched intermittently in conjunction with licking motions of the tongue. The extent to which this transposition of functional activity from diaphragm to sternomastoid, or tongue to sternomastoid is operative in the fully awake animal is uncertain. Nevertheless, the appropriate circuitry and functional capacity of the phrenic and hypoglossal motorpools apparently can be diverted through a cross-nerve anastomosis to a muscle (the sternomastoid) that is not primarily responsible for breathing or licking activities.

The functional consequences of self-reinnervation, rather than cross-reinnervation, have also been answered in part by Guth and coworkers[2] who demonstrated in the rat that the recurrent laryngeal nerve, some fibres of which normally transmit efferent bursts synchronous with those of the phrenic nerve, is often capable of restoring rhythmic diaphragmatic activity subsequent to a recurrent laryngeal-phrenic nerve anastomosis

Sperry[3], in still earlier studies, emphasised that a regenerated nerve tends to retain its original reflex activity.

Thus, in spite of the disparity in muscle nerves (with respect to quality and quantity of efferents and afferents, and the differences in central circuitry) there is good reason to assume that many of the nerves used in cross-reinnervation experiments continue to elicit a gross pattern of muscle activity quite similar to that of their original musculature. It is difficult, however, to envisage a precise replication of function in most cross-reinnervated muscles because of the extreme complexity and uniqueness of each nerve, each muscle, and the myriad factors interwoven in the nerve regeneration process.

2 Guth, L., Soutter, L., Frank, K., Campbell, J. B., and Lloyd, J. B., *Expl Neurol.*, **2**, 251 (1960).
3 Sperry, R. W., *Q. Rev. Biol.*, **20**, 311 (1945).

THE AUTHORS REPLY:— Dr Yellin's observations are certainly pertinent to the question posed by us, and are also in line with expectation following the pioneering work of Sperry[2] to which Dr Yellin refers. The broader problem to which our query relates, however, is whether the altered patterns of motor nerve impulses which probably reach both fast-twitch and slow-twitch mammalian skeletal muscles following cross-reinnervation are by themselves sufficient to bring about the mechanical and biochemical changes which are now known to follow altered innervation. For this to be so at least four conditions must be met.

First, it must be established that alterations in the number, and or, pattern of nerve impulses reaching a normal muscle can alter that muscle's mechanical and biochemical characteristics.

Second, it must be demonstrated that following cross-reinnervation, there is an altered pattern of motor activity in the reinnervated muscles.

Third, it must be shown that the change in activity pattern following cross-reinnervation is quantitatively correct to account for the observed mechanical and biochemical changes.

Fourth, it is also necessary to demonstrate that the observed changes in the mechanical and biochemical characteristics of cross-reinnervated muscle are the direct result of the number, and or, pattern of motor nerve impulses, and are not due to some concomitant metabolic change occurring in the motoneurone as a consequence of its altered activity.

The first point is now established beyond doubt by the original experiments of Salmons and Vrbová[3], and the later work of Streter *et al.*[4] and Al-Amood *et al.*[5]. Dr Yellin's observations add weight to the expectation that the electromyographic activity of both fast-twitch and slow-twitch muscle is altered by cross-reinnervation, but, as he implies in his letter, the satisfying of the third requirement must await the quantification of the appropriate electromyograms from conscious, unrestrained, cross-reinnervated animals.

At the present stage of knowledge, consideration of the fourth requirement can only be speculative[5,6] but it is clear that if the changes following the cross-reinnervation of mammalian fast-twitch and slow-twitch muscles are to prove entirely explicable in terms of the pattern of motor nerve impulses reaching the muscles, all four criteria listed above must be satisfied. Only then can the additional possibility of another neural (trophic) factor operating in this situation be firmly rejected.

Measurement and Classification of Psychiatric Symptoms

J. K. WING, J. E. COOPER and N. SARTORIUS

This book lays down clear definitions of the experiences which constitute psychiatric symptoms and describes an interview technique which allows the symptoms to be reliably recorded. Once rated, the symptoms can be grouped to aid diagnosis. The importance of the book is that it shows how a substantial part of the variability in making psychiatric diagnoses, due to the large subjective element in defining, recognising and classifying symptoms, can be brought under control and hence more reliability can be brought into the diagnosis and treatment of psychiatric disorders.

An Introduction to Logical Design of Digital Circuits

C. M. REEVES

An introductory course on the logical design of computers. This will form part of the curriculum of courses in computing science in order to provide all students with a common ground of intellectual appreciation of the principles of hardware design and operation, whether their ultimate speciality will be in computer design or in the applications of computing.

Fortran Techniques

A. COLIN DAY

A practical description of many of the commonly used programming techniques required in both numerical and non-numerical applications of Fortran. It is written for non-specialist users who have already completed a course in basic Fortran programming, but who may have only a minimum knowledge of mathematics.

Applied Animal Ethology

An International Scientific Journal reporting on the Application of Ethology to Animals used by Man.

Editor-in-Chief:
A. F. FRASER, Department of Veterinary Reproduction, Royal (Dick) School of Veterinarian Studies, University of Edinburgh, Edinburgh, Great Britain.

Associate Editor:
D. G. M. WOOD-GUSH, Poultry Research Centre, Agricultural Research Council, Edinburgh, Great-Britain.

Editorial Advisory Board:
G. Alexander (Blacktown), G. W. Arnold (Wembley), B. A. Baldwin (Cambridge), R. G. Beilharz (Parkville), G. C. Brantas (Beekbergen), J. F. Eisenberg (Washington), I. Ekesbo (Skara), Y. Espmark (Stockholm), R. Ewbank (Liverpool), M. W. Fox (St. Louis), J. B. Free (Harpenden), V. Geist (Vancouver), H. B. Graves (University Park), G. Greenberg (Wichita), E. S. E. Hafez (Detroit), B. L. Hart (Davis), M. Kiley (Brighton), R. Kilgour (Hamilton), J. K. Kovach (Topeka), P. Leyhausen (Wuppertal-Elberfeld), A. Littlejohn (Onderstepoort), F. Loew (Saskatoon), F. O. Ödberg (Gent), G. C. Perry (Bristol), S. Ross (Washington), Y. Ruckebusch (Toulouse), H. H. Sambraus (München), M. W. Schein (Morgantown), J. P. Scott (Bowling Green), J. P. Signoret (Monnaie), H. Ursin (Bergen), G. van Putten (Zeist), K. Zeeb (Freiburg).

The journal will deal with all animals domesticated in any fashion. Subjects will range from mammals (cattle, pigs, horses, sheep, goats, camels, dogs, cats, deer, fur-animals, etc.) through birds (poultry, cage birds, racing-pigeons) to insects (honey-bees). It will also be concerned with feral relations of domesticated animals, animals living in zoos and safari parks and animals on the perimeter of domestication (red deer, wildebeest, eland, etc.). Experiments with laboratory animals will only be included if the results obtained are of direct relevance to the understanding of domesticated animal behaviour. Papers dealing with behavioural physiology will be acceptable if the main emphasis of the work is on behaviour.

Besides carefully designed ethological studies in depth, this new journal will accept carefully documented behavioural data – often gathered as a side result to agricultural or veterinary studies.

APPLIED ANIMAL ETHOLOGY will be of interest to those working with domesticated animals (agricultural scientists, veterinarians and zoologists), with animals in zoos and safari parks and with wild animals (ecologists, conservationists, curators).

APPLIED ANIMAL ETHOLOGY will be published quarterly, four issues constituting one volume. The first issue will appear in the third quarter of 1974.

The Subscription price is Dfl. 82.00 (about US$ 29.80) per volume, plus Dfl. 8.50 (US$ 3.10) postage.

Authors are invited to submit suitable manuscripts to:
Editorial Office Applied Animal Ethology,
P.O. Box 330, Amsterdam, The Netherlands
A detailed guide to authors is available.

Free specimen copies are made available on request.

Livestock Production Science

Official Journal of the European Association for Animal Production.

Editor-in-Chief:
H. de BOER, Research Institute for Animal Husbandry, "Schoonoord", Zeist, The Netherlands.

Editors:
J. KIELANOWSKI (Warszawa)
A. NEIMAN SØRENSEN (København)
H. SKJERVOLD (Ås)

Editorial Advisory Board:
C. Béranger (Theix), R. Boccard (Theix), A. H. Carter (Hamilton), A. De Vuyst (Lovenjoel), C. R. Henderson (Ithaca), J. Hodges (Vancouver), A. Horn (Budapest), P. Jonsson (København), A. Kiener (Berne), Y. Nishikawa (Kyoto), V. A. Oyenuga (Ibadan), F. Pirchner (Freising/Weihenstephan), D. Plasse (Maracay), R. D. Politiek (Wageningen), A. A. Rérat (Jouy-en-Josas), A. Schürch (Zurich), G. R. W. Spedding (Hurley), F. Torres (Balcarce), R. W. Touchberry (St. Paul, Minn.), A. Vaz Portugal (Lisboa), K. O. von Selle (Roma).

The intention of the European Association for Animal Production and the publishers is to provide a medium for the publication of original studies and comprehensive reviews in the field of livestock production, and for the exchange of current views, thereby contributing to the sound development of this branch of activity. The journal will deal with fundamental aspects of farm animal production and the incorporation of research results into objectives and systems of livestock production. It will cover cattle, pig, horse, sheep and goat production – their housing, feeding, nutrition, management, health, and aspects of breeding, as well as pollution control, and advisory activities.

Papers concerned with the quality of animal products and their processing or with the technical and economical aspects of the subject field will only be accepted if they bear relation to animals or animal production.

Contributions from related disciplines of animal production should contain information of direct significance to livestock production.

LIVESTOCK PRODUCTION SCIENCE will be published in one volume per year in quarterly issues, the first of which appeared in February 1974.

The Subscription price is Dfl. 77.00 (about US$ 28.00) per volume, plus Dfl. 8.00 (about US$ 2.90) postage.

Authors are invited to submit suitable manuscripts to:
Editorial Office Livestock Production Science,
Driebergseweg 10D
Zeist, The Netherlands

Free specimen copies are made available on request.

book reviews

Mathematics of the Universe

The Large Scale Structure of Space-Time. By S. W. Hawking and G. F. R. Ellis. Pp. xi+391. (Cambridge University: London, May 1973.) £10; $28.50.

THERE has been a considerable upsurge of interest in general relativity theory over the past ten years or so. This is undoubtedly partly due to several remarkable discoveries in observational astronomy in recent years (quasars, pulsars, the microwave background, explosions in galactic centres, and so on) which indicate the presence of gravitational fields in nature so strong that Newtonian theory seems unlikely to be completely adequate. But equally important to Einstein's theory, and largely independent of such observational considerations, have been a number of mathematical developments in the theory. The work of Bondi, Sachs and others on the positivity of energy carried by gravitational waves was an important landmark. So was the development of techniques for finding exact solutions of Einstein's field equations, leading to the discovery by Kerr of a solution representing the field of a rotating isolated source. More recently, topological methods have been developed and have proved to be increasingly valuable for the treatment of problems where an exact analysis is not yet feasible. It has been possible, in particular, to conclude that the presence of singularities in solutions of Einstein's equations is not just a feature of the high symmetry that had been normally assumed. It is now known, for example, that irrespective of symmetry the collapse of a massive star will, according to Einstein's theory (once a point of no return has been reached), result in a space–time singularity where it is to be expected that densities and curvatures will diverge to infinity. A similar singularity occurs in the initial stage of the expansion of the Universe—again irrespective of symmetry. In the case of a collapse, the resulting black hole can be studied by a variety of techniques, with topological and analytical arguments each enhancing the value of the other. These results have been the work of several different theorists, the name of S. W. Hawking being pre-eminent among them.

Until recently, no complete account of these later topological and related developments has been available, but the situation is now happily remedied with the publication of this book. It is an impressive *tour de force*. It starts with a detailed but rapid introduction to differential geometry; this is followed by a discussion of the physical basis of Einstein's equations; then there is an elaborate discussion of conjugate points on geodesics; next, many of the most important exact solutions of Einstein's field equations are studied in detail, including Kerr's solution, the frequent use of space–time diagrams being a most welcome feature; causal properties of space–times are then discussed and several useful theorems are proved; asymptotically simple space–times are analysed; then there is a detailed discussion of the Cauchy problem; the singularity theorems are next described and proved in detail; the Schmidt *b*-boundary is introduced to give a precise definition of a singularity; then the black hole theorems are discussed and proved; finally there is an analysis of the status (derived partly from observations of the microwave background) of the initial big bang singularity. Much of the later material is presented here for the first time; the book also is a remarkably complete survey of the relevant material. This book is clearly a 'must' for any advanced student who wishes to follow up these modern developments in any detail.

But he will have to work hard. The book is not, in my estimation, at all an easy one to study in detail. Much useful information can, no doubt, be obtained by browsing and the flavour of the arguments can be ascertained. But for a detailed appreciation of the techniques, there is a number of serious obstacles for the student. Some of these are intrinsic to the subject. The very breadth of knowledge involved, ranging from pure mathematics to observational astronomy, is in itself a serious hurdle. Most of the book is mathematical in nature. But it is relevant mathematics. Little concession is made to mathematical elegance for its own sake and this can make for difficulties in reading. I had the feeling also that in many places the arguments could have been simplified and greatly clarified by a certain amount of reorganisation. But it is perhaps unfair to ask of the authors that they should have produced a polished gem of clarity for work which is so new. One knows only too well the enormous extra labour that can be involved when one attempts to reduce a presentation to its best possible form.

Nevertheless, I feel that certain points of criticism may reasonably be made. There are several small errors and ambiguities present which can make reading difficult. (I noticed something like sixty of these but I found no serious errors. It should be pointed out that with the association of tensors with forms that is quite reasonably made, a factor $n!$ should occur with the definition of the integral of an n form; relation (3) on page 32 is wrong; proposition 4.5.12 seems not to be true as stated; some of the diagrams suffer from being inaccurately drawn, such as in Fig. 31, the "matter world-line" seems to be spacelike.) Also, key definitions are often given in the middle of paragraphs and can come upon one unexpectedly (for example on page 195 a local causality neighbourhood is defined in parenthesis). Perhaps this need not be a drawback if done systematically, but the concept of "Cauchy development" is essentially defined three times, on page 60, page 119 and page 201.

I should have been happier if the physical significance of the metric g had been made more clear cut, defined by the behaviour of clocks as emphasised by Synge and Bondi. I feel it is a pity that the causality and chronology symbols $<, \ll$ are not used, since they can greatly simplify the presentation of some arguments. The terminology 'closed trapped surface' is used frequently in the book, but I found no mention of a 'trapped surface'. A reversion to this latter (original) terminology would seem a worthwhile simplification. Whereas indexed symbols are used to denote sets of components rather than actual tensors, there are places where the notation seems, rather confusingly, to indicate the contrary. In the discussion of the Cauchy problem in chapter 7 there are many very detailed formulae but little explanation of the ideas involved. I found this very hard to follow. So also were a number of other proofs. The black hole collision depicted in Fig. 60, and in particular the behaviour of the apparent horizons, is not supported in the text by any formal statements. The conjectural aspects of this picture should have been brought out. I feel that credits are

sometimes given rather haphazardly (for example there is no mention of Newman in connection with the charged Kerr solution, nor of Bondi in relation to the mass carried by gravitational waves). Finally, the absence of any discussion of 'mixmaster' singularities or of any details of the Belinskii – Lifshitz – Khalatnikov work seems to me to be a serious omission.

I would like to emphasise that these criticisms are basically minor ones in view of the formidable and impressive task undertaken by the authors. They have succeeded admirably and their work is undoubtedly a landmark in the presentation of modern gravitational theory.

The question of where the universe comes from and where it is going cannot fail to be of interest to everyone. There is rather little in science which directly bears on this question, but if anything seems to, it is surely the subject matter so powerfully presented in this book.

ROGER PENROSE

Food manufacture

Biology and the Food Industry. By H. R. Barnell. Pp. 59. (The Institute of Biology's Studies in Biology, No. 45.) (Arnold: London, February 1974.) £1.50 boards; 75p paper.

THE story is told of an Oxford undergraduate who obtained consistently good grades for his essays by copying from the *Encyclopedia Britannica* which his tutor had never read. To help "students at school, college and university . . . to keep abreast of recent trends and know where the most significant developments are taking place", the Institute of Biology sponsors the preparation of a series of booklets on selected aspects of biology to supplement the more substantial but inevitably finite treatment of biology which a textbook could be expected to provide. The late Dr Rex Barnell has written such a booklet about the food industry. In it he has systematically described such salient features of manufacturing processes and methods of food preservation as could be expected within the constraint of 59 pages, bearing in mind that he had also to touch on food composition, nutrition and the future. He has performed his task well and both pupils and their teachers will be grateful whether or not there may be some readers who feel a sneaking sympathy for the Oxford tutor.

Here will be found the distinction between drying and dehydration, a definition of a convenience food, description of pasteurisation, canning, chilling, freezing, irradiation and four lines about pickling. Ten pages suffice for milling, baking and margarine making. Vegetable meats, leaf protein and micro organisms grown on hydrocarbons get seven pages. It is all very neatly done. The section devoted to nutrition and food quality sensibly draws attention to the contribution manufacturers make to an adequate diet by making their commodities readily available. In the breathless pace, however, figures for energy value seem to have slipped out of the table of "recommended intakes". The book ends on a high note with the promise that "it is by no means impossible that if groups of biological, physical and chemical research workers concentrate on the problems . . . virtually unlimited supplies of food . . . may be truly synthesised . . . from constituents of the earth's atmosphere and crust". Well, perhaps they may.

MAGNUS PYKE

Reactions at electrodes

The Chemistry of Electrode Processes. By Ilana Fried. Pp. x+225. (Academic: London and New York, January, 1974.) £4.90; $13.75.

RECENTLY, a number of books have appeared based on the study of electrode reactions or electrodics. According to the author, this monograph is designed as "an introduction to electrodics" for "the advanced student or the qualified chemist" who possesses "no familiarity with electrochemistry". The author has succeeded in achieving her goal and has produced a concise and very readable book. Every section is prefaced by a clear statement of the question to be answered and derivations have been kept simple by mixing rigorous treatments with comparisons and analogies. The SI unit system and IUPAC conventions have been adhered to throughout. Furthermore, the book contains a balance between theory, experimental details and areas of application.

The book is divided into six chapters; the first two are brief and introduce the area of interest, the fundamental concepts and definitions. The third chapter deals with the kinetics of electrode reactions by developing the relationships between current, potential and time for both reversible and irreversible electron transfer processes. Moreover, irreversible processes caused by slow chemical reactions preceding charge transfer and reactant adsorption are also considered. Finally, the influence of cell impedance on the current-potential behaviour is discussed. The fourth chapter which completes the theoretical part of the monograph is devoted to the electrode–solution interphase. Various models of the double layer are evaluated and the modern model which offers the best fit to the experimental results is described. The topic of specific adsorption is also examined because of its effects on the double layer. The final section discusses how electrode reactions are influenced by the electrode–solution interphase.

The fifth chapter introduces the methodology of electrode reactions. Included in this section are descriptions of cells, electrodes and apparatus; equilibrium measurements of capacitance and impedance; voltammetric methods; and potential, current and charge step techniques together with their limits of applicability. The chapter concludes by mentioning the techniques of reflection spectroscopy and transmission spectroscopy at optically transparent electrodes. One drawback to this chapter, in particular, is the lack of references to the literature. In fact, the bibliography contains only a selection of books that the author "found useful" and omits all references to recent reviews and original contributions.

The final chapter offers little more than an indication of the number of areas where electrode reactions are involved, for example, corrosion, electroplating, and fuel cells. This broad survey was too ambitious and the author would have been more successful in illustrating the applications of electrodics by examining, in detail, a limited number of solutions to problems related to the areas mentioned. Such an approach would have supplemented the material of chapter 5 and, by involving the reader in the problem-solving process, would have further familiarised him with the study of electrode processes.

C. M. ELSON

Cultured plants

Plant Tissue and Cell Culture. Edited by H. E. Street. Pp. viii+503. (Botanical Monographs, Vol. 11). (Blackwell Scientific: Oxford and London, 1973.) £12.50.

ALTHOUGH plant tissues were first cultured *in vitro* 35 years ago, the realisation of their potential has always seemed to remain tantalisingly in the future. The technical problems of initiating and maintaining cultures of all but a few particularly favourable plants have until quite recently seemed insuperable obstacles to achieving the ready answers to physiological questions that the tissue and cell culture approach seems to offer. This excellent book should completely dispel that notion. Professor Street has a knowledge and experience of the culture of plant tissues, and particularly plant cells, that is second to none, and with his cust-

omary energy and enthusiasm has produced a superb account of the technicalities and potentialities of treating plants as microorganisms. He has been ably assisted in this by first-class contributions from a group of experts in specific aspects of the topic, although the editor's organising and integrating influence can be discerned throughout the book.

Approximately half of the book is devoted to a careful and comprehensive description of the many different techniques available for the culture of plant tissues and cells, beginning with an extremely useful account of the basic essentials of a tissue culture laboratory written by the editor himself. Street also provides a chapter on the apparatus and methods necessary for the successful cultivation of plant cells as suspension cultures. This includes full descriptions of batch culture chambers and of automatic chemostat and turbidostat devices. The technicalities of initiating and maintaining callus cultures are admirably covered by M. M. Yeoman, from Edinburgh, whilst E. C. Cocking and P. K. Evans of Nottingham discuss the isolation, culture and potential of plant protoplasts. The exciting topic of the production of haploid cell lines, with their obvious implications for plant genetics, receives a scholarly review by N. Sunderland, from the John Innes Institute, in a chapter dealing with pollen and anther culture. The general cytology of cultured cells is described in a long, informative chapter jointly written by Yeoman and Street, and Sunderland separately discusses the vexing question of the karyological instability of plant cultures.

The growth pattern of callus cultures and cell suspension cultures is treated in depth in separate chapters by Yeoman and P. A. Aitchison, and by P. J. King and Street. The discussion on cell suspension cultures is particularly valuable since it not only provides information on the growth and physiology of isolated plant cells, but also shows in great detail how highly synchronous populations of cells may be established. Such cultures can exhibit a remarkable synchrony of cell division for up to eight generations and, with a cell cycle of around three days long, their potential for the intensive investigation of the control mechanisms of the cell cycle must surely be greater even than that of the yeasts and unicellular algae. The book is rounded off by discussions of organogenesis and embryogenesis (J. Reinert, Berlin), the culture of plant tumour cells with special reference to crown gall (J. N. Butcher, Cambridge), and the growth of plant parasites in culture (D. S. Ingram, Cambridge).

Plant tissue culture is no longer an end in itself; it has progressed to a point at which it can be considered to be a highly sophisticated technique capable of providing answers to problems throughout the whole of plant biochemistry, physiology, development, genetics and pathology. This beautifully produced book will be invaluable to the rapidly growing number of plant scientists who wish to use plant tissue or cell culture, but who do not wish to devote their time to becoming experts.

HARRY SMITH

Big game ecology

Wildlife Ecology. By A. N. Moen. Pp. xvi+458. (Freeman: San Francisco; 1973.) $17.50.

SYSTEMS analysis and predictive model building in ecology are at an interesting stage in their development. More and more autecological studies pour out increasing quantities of details for synecologists to work on. This book is a synecological study of north American big game. It is unique in that it attempts to describe the physical and biotic interactions of game with their environment and to assess the importance of these interactions in terms of overall productivity. Their influence on game and range management are clearly stated. The title of the book is misleading, for only a small amount of space is devoted to wild fowl, gallinaceous birds and other wild life. Most of the data and examples are taken from studies on elk (wapiti), mule and white tailed deer and caribou.

The chief value of this book is that it brings between two covers a multitude of details regarding methods of measuring environmental parameters. Working ecologists and game managers need to know these details, but cannot afford much time ferreting them out. They will find this aspect of the book most appealing. Particularly useful in this respect are the two chapters which deal with the effects of climatic conditions on physical characteristics of the environment and on large ungulates. The functional relationships between weather and organisms are minutely analysed from the viewpoint of transference of thermal energy. The distribution of thermal energy is the commonest bond in these relationships and from this is drawn a conceptual picture of the complex nature of heat exchange involving all the basic modes of heat transfer. Anyone actively involved in game management, as well as theoretical modellers, will find this section of the book of immense value.

Physiological and behavioural interactions between game and environment are covered in the first half of the book in thorough, but not long winded, detail. The second half deals with the analysis of interactions involving both these biotic interactions and the physical ones. Emphasis is laid on that essential statistic for range managers, the carrying capacity of the habitat. Effective calculation of this is possible only by computer simulation and integration of models of all aspects of the system being analysed. The author suggests a useful working format that such models should follow.

This book has, to my mind, two outstanding merits. The first is that it paints a detailed picture of the ecology of northern big game, in the style of Canaletto rather than that of the Impressionists. This alone should commend it to the attention of pure and applied ecologists alike. The second is that the book inspires the reader to think big; in terms of systems rather than species. For the development of ecology this seems like a good thing and for successful environmental manipulation an essential thing.

Good game management, like all ecosystem management, demands that decisions be taken on ecological bases. The benefit of step by step model building means that decisions taken can, before implementation, be tested by computer simulation. The degree of similarity between computer prediction and observed dynamic change depends on the realism of the biological models involved in the computation. No one must forget that this is the fundamental core of ecology which always has and always will depend on the skills of the individual field ecologist. As far as north American big game are concerned, this book brings us one step nearer rational management.

D. MICHAEL STODDART

Rho–sigma relations

The Hammett Equation. By C. D. Johnson. Pp. viii+196. (Cambridge University: London, October 1973). £4.50; $13.50.

TO L. P. Hammett is owed the recognition that polar effects of aromatic substituent groups on rate and equilibrium constants of side-chain reactions are quantitatively regular. This conclusion is formally expressed by Hammett's $\rho\sigma$ relation, to which the volume under review is devoted.

The author provides an elementary, yet fairly detailed account of the role of Hammett's treatment in organic chemistry. It is intended for senior undergraduate or first-year graduate students, a formidable aim since, even for the simplest cases, general statements have to be tempered by ifs and buts. The book describes the various developments of the original $\rho\sigma$ treatment and provides a guide to the brood of modified sub-

stituent constants (for example σ^+, σ^-, σ^*, σ°, σ_I, σ_D, σ_R, σ^n, σ^G) which, on the one hand, extend its practical usefulness and, on the other hand, rob it of its beguiling simplicity and blur its theoretical significance.

It can be argued that the two chief motive forces for the development of science are the establishment of unifying principles (which provide the landmarks in the history of science) and the destruction of these same unifying principles by the experimental falsification of their predictions. Although Dr Johnson would hardly present the issue in those terms, the Hammett equation provides an interesting illustration of the interplay of these forces in the current development of chemistry.

V. GOLD

Quantum mechanics

Principles of Quantum Mechanics: The Non-Relativistic Theory with some Illustrative Applications. By W. V. Houston and G. C. Phillips. Pp. xi+376. (North-Holland: Amsterdam, 1973.) Dfl.110; $44.

THIS book covers the standard undergraduate course in quantum mechanics. In the introduction it is suggested that students should already have met some of the physical ideas but in fact the book is self contained and would be a suitable textbook for a full year's course for students who have no previous knowledge of the subject. In a field which is already reasonably well populated with good textbooks this volume will not be out of place. It cannot, however, claim to have any significant new features.

It is hard to see how the chapter on classical mechanics fits into the general scheme of the book. Although it is sometimes claimed that Poisson brackets and the Hamilton–Jacobi equation are an aid to an understanding of quantum mechanics these topics do not appear to be used at all in the presentation of quantum mechanics given in this book so their presence in chapter 2 is an unnecessary hurdle for the student. Another slightly unsatisfactory feature is that a reader might be left with the impression that there are two rival 'quantum theories' which happen to give similar results, namely wave mechanics and formal quantum theory. Of course it is clearly stated that these are equivalent but the method of presentation, even involving two separate sets of axioms, is not conducive to making this obvious. The notation used in chapter 8 does not always help.

Several sections of the book, for example the chapter on scattering theory, do not make easy reading but this is partially due to the fact that more care is taken in presentation than in some similar books.

The many interesting examples in the book will be found useful, as will the brief mathematical appendix.

E. J. SQUIRES

Condensed matter

The Structure and Properties of Solids: The Crystal Structures of Solids. By P. J. Brown and J. B. Forsyth. Pp. 172. (Arnold: London, July 1973.) Boards £4.40; paper £2.20.

THIS book aims to give an understanding, at undergraduate level, of the important elements in the study of the crystal structure of solids. There are chapters on crystallographic geometry and symmetry, the production and properties of X rays, neutrons and electrons, and the theory of diffraction, including the scattering of the different radiations. The experimental study of diffraction is described, and is followed by three chapters describing, and to some extent rationalising, the structures of the elements, ionic compounds and binary alloys.

To attempt to describe all this body of work inside 172 pages is itself a major achievement, and the authors certainly have given the reader a large amount of information at a relatively low price. The book also contains much useful practical information not usually found in physics textbooks. For example, the use of the ASTM index for identifying powder patterns is described in detail, and the 'cross-multiplication' rule for calculating the zone indices of the intersection of two planes is given. Both of these aids are used frequently by crystallographers in practice, and it is good to see them (and many more) in a book of this kind.

It is perhaps not surprising that the authors have had some difficulty in coping adequately with the wide range of subjects in such a slim volume. For the book is really a distillation of three types of book: one on crystal symmetry, like Phillips' *Introduction to Crystallography*; one on diffraction theory and techniques; and one like Evans' *Crystal Chemistry*. Though it would be nice to think that an undergraduate could master all this information quickly because it is presented in a concise way, I must say I am sceptical. Much of the writing is almost in note form, and the level of explanation is often such that I can only understand the point made, because I, like the authors, have studied the subject before in a more leisurely fashion.

The list of topics to leave out is clearly the key decision in a book of this length, and although no two authors would agree on the list, the choice seems to have been exercised somewhat unevenly. Rather complex examples of non-crystallographic point groups and the idea of magnetic symmetry are introduced in chapter 1, and the complete derivation of the formula for the integrated diffracted intensity is in chapter 3. But space has not been found in chapter 5 for a description of how crystal structures are experimentally determined; after the formal theory, the reader could usefully be rewarded with at least a simple example of a structure determination.

Apart from this inexplicable omission, the book is a very good summary of the various aspects of the study of crystal structures. As such it will be useful for research workers who wish to survey the field quickly. It could also be usefully used as an undergraduate text; however, thought should be given to the speed at which the topics can be mastered, as there is as much material here as in most books of three times the length.

J. A. VENABLES

Dirty air

Fundamentals of Air Pollution. By A. Stern, H. C. Wohlers, R. X. Boubel and W. P. Lowry. Pp. xiv+492. (Academic: New York and London, September 1973.) $14.50.

THIS book represents a welcome addition to the literature on air pollution and will serve primarily as an introductory book to the field. It is divided into four parts respectively on the elements, effects, meteorology and control of air pollution. The authors intended to introduce the topic in part 1, which together with part 2 defines the problem, and to resolve it in parts 3 and 4. These objectives are not completely met and the book gives the impression of being four short books condensed into one. It is difficult for instance to understand why the sections dealing with sampling and analysis (chapters 14 and 15) have been included under "The Effects of Air Pollution" while the section dealing with isokinetic sampling techniques occurs in part 4.

Much of the analytical work is presented very poorly with undue emphasis on classical procedures. In contrast the meteorology section is well presented and informative. The section which must receive the greatest criticism is that on the control of air pollution. Here the authors go back to consider sources of air pollution and sampling techniques, devoting only twenty pages to the engineering control of emissions from both vehicles and industrial processes. This, in a book of 450 pages, is surely inadequate.

R. PERRY

WILEY INTERSCIENCE

Following the interest aroused by the Editorial in the April 26th issue we are pleased to provide further information on :

THE D.N.A. STORY

A colour film about one of the scientific dramas of the century : the race which ended in the discovery of the double helix as a workable structure for DNA. The film describes, in their own words, the interplay of the work of James Watson and Francis Crick at Cambridge and Maurice Wilkins at King's College London, and Linus Pauling at Caltech.
The four men prove to be engaging raconteurs as they take us through the events leading up to final success in 1953. With the edge of controversy now dulled we are offered through the scientists' laconic description, a fresh and entertaining study of the fascinating issues involved at many levels in this remarkable human achievement. On the technical level, the rise of molecular biology with its foundation in crystallography and the capacity of model-building to give tangible form to diffuse X-ray patterns are put in historical perspective. Scientific arguments are developed as needed for the narrative—as in Watson's book, *The Double Helix,* the scientists do not talk down to their audience. However, the film can profitably be shown to any level of student audience if it is preceded by discussion of the relevant fundamental biochemistry. (Wiley's prize-winning teaching film, *DNA Blueprint of Life,* might be ideal.) *The DNA Story* does not claim to teach the biology of DNA: rather it is a valuable illustration to supplement a biochemistry, biology or general science course and an excellent and enjoyable introduction to the exciting and usually remote world of scientific research. For the better informed the film should prove to be a most important historical document.
May 1974 Running Time: 45 minutes £175.00

GENE EXPRESSION Volume 1. Bacterial Genomes

By **Benjamin Lewin,** *editor Cell.*
This volume discusses bacterial gene systems. The first part describes the breaking of genetic code, the mechanisms of protein synthesis, and the characteristics of the components of the protein synthetic apparatus. The second section deals with the control of gene expression, discussing the mechanism of RNA synthesis, the control of transcription and translation of the lactose, operon of E. coli, and the different forms which control systems may take in other bacterial operons and in bacteriophages. The final section discussed the systems responsible for the reproduction of DNA, including the replication process itself, the systems which modify, restrict, repair and recombine DNA, and the nature of the cell cycle.
June 1974 660 pages £10.00 (cloth)
600 pages £4.75 (paper)

BLOOD FLOW AND MICROCIRCULATION

By **Stanley E. Charm,** *Tufts University School of Medicine,* and **George S. Kurland,** *Harvard Medical School and Beth Israel Hospital, Boston.*
Assembles the available knowledge on rheology and flow in the microcirculation with emphasis on methods for quantitation of flow in a variety of circumstances. Illustrative numerical examples of calculation are presented to familiarize the reader with the mechanics of problem solving. Includes computer programs for the analysis of flow and a review of the clinical significance of altered viscosity.
March 1974 254 pages £10.20

FEMALE REPRODUCTIVE SYSTEM: Dynamics of Scan and Transmission Electron Microscopy

By **Alex Ferenczy, M.D.,** *College of Physicians and Surgeons, Columbia University,* and **Ralph M. Richart, M.D.,** *College of Physicians and Surgeons, Columbia University, Presbyterian Hospital, New York City, and International Institute for the Study of Human Reproduction.*
Gathers the best electron microphotographs of the female genital tract available and arranges them by organ system; vulva vagina, cervix, endometrium, myometrium fallopian tube, ovary and placenta. Textual discussion accompanies photographs. 143 slides will be available separately.
May 1974 414 pages £15.25

JOHN WILEY & SONS

John Wiley & Sons Ltd Baffins Lane Chichester Sussex PO19 1UD England

The Physics of Liquid Crystals

P. G. de Gennes

The study of liquid crystals is complicated because it involves several different scientific disciplines, specialized tools such as nuclear magnetic resonance, and also a certain sense of vision in three-dimensional space in order to visualize complex molecular arrangements. Professor de Gennes' treatment of his subject will be interesting and useful to every research worker in the field, and to graduate students in chemical physics, solid-state physics, mechanics, and engineering. The book contains chapters on Anisotropic Fluids, Long- and Short-Range Order in Nematics, Static Distortion in a Nematic Single Crystal, Defects and Textures in Nematics, Dynamical Properties of Nematics, Cholesterics, and Smectics. £11·50 *International Series of Monographs on Physics 13 June*

Asymptotic Analysis

J. D. Murray

This book is intended principally for advanced undergraduate or beginning post-graduate mathematicians and for scientists aiming to get answers to practical problems. An introduction to asymptotic expansions is followed by chapters on the main techniques for obtaining analytical approximations to integrals, the class of integrals which arise from Fourier and Laplace transform solutions of differential equations, with a brief introduction to the important subject of singular perturbation theory. £3·50

Thomas Harriot

Renaissance Scientist

John W. Shirley

Harriot was the first Englishman to make a telescope, and his moon maps are the earliest known telescopic observations of the moon. His sun-spot observations are also the earliest that survive. In addition to producing highly sophisticated work on the theory of mathematical navigation, he was also a practical scientist and represented Sir Walter Raleigh in the first British colony in the New World. Recent discoveries of many of Harriot's actual observations and calculations make this new estimate of his contribution to science especially timely. Illustrated £6·50 *13 June*

Oxford

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, **'Molecular Biology Comes of Age'** looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of **'Molecular Biology Comes of Age'** are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

APPOINTMENTS VACANT

DALHOUSIE UNIVERSITY
Nova Scotia, Canada
DEPARTMENT OF ANATOMY
TWO ASSOCIATE OR ASSISTANT PROFESSORS

Applications are invited from persons with a Ph.D. or a professional qualification for the above positions. Duties may include the teaching of Anatomy to Medical, Dental or Paramedical students. An ability to teach gross anatomy and a research interest in the nervous system would be an advantage. Salary (minimum $15,000) and rank commensurate with experience. Applications together with curriculum vitae and the names of two referees should be addressed to Dr. D. G. Gwyn, Department of Anatomy, Dalhousie University, Halifax, Nova Scotia, Canada by June 20, 1974. (1881)

BAMFIELD MARINE STATION
POSITION OF DIRECTOR

The Management Council of the Western Canadian Universities Marine Biological Society (WCUMBS) invites applications for the post of Director of its Marine Laboratory at Bamfield on the west coast of Vancouver Island, British Columbia, Canada. The position will be full-time but the incumbent will probably be associated in an honorary or part-time capacity with one of the member Universities of WCUMBS (Alberta, British Columbia, Calgary, Simon Fraser or Victoria). Salary will be negotiable.

Applicants should supply a brief biography including degrees, attainments and experience, a list of publications, the names of 3 referees and a statement of research interests. Views on the functions of a new marine laboratory serving a group of universities would be helpful to the Selection Committee.

Applications close on August 31, 1974 and should be sent to Dr. D. M. Ross, President, WCUMBS, c/o Faculty of Science, University of Alberta, Edmonton, Alberta, T6G 2E9, Canada, who will supply further particulars about the position, the Station and the Society upon request. (2131)

GEOPHYSICAL INSTITUTE
UNIVERSITY OF ALASKA
PROFESSOR OF SEISMOLOGY

Applications are invited from highly qualified and experienced persons for the senior post in seismology. The professor will have overall responsibility for the planning and operation of the Institute's seismic research in Alaska and for conduct of the graduate program in this field. An appointment at the associate professor level may also be considered.

The Geophysical Institute has three major areas of basic and applied research—solar-terrestrial science, meteorology and glaciology, and the solid-earth sciences. Solid-earth research currently includes seismology, gravity, volcanology, paleomagnetism, geochronology and geochemistry. Much of the effort is focussed upon plate interactions relating to Alaska and the Arctic.

The appointment will be made initially for two years, subject thereafter to confirmation and indefinite extension.

For further information and application procedures, please write to the Director, Geophysical Institute, University of Alaska, Fairbanks, Alaska 99701 USA. (2179)

Agricultural Development and Advisory Service

ADVISORY OFFICERS

The Agriculture Arm of ADAS provides farmers and growers with technical information and advice on agricultural and horticultural matters, and carries out investigational, development and promotional work. For most appointments an important part of the work is the monitoring of current trends in order to provide accurate information. Vacancies exist, in various parts of England and Wales, in the following fields:

Agriculture

The main aim in this field is to increase agricultural productivity. To achieve this officers advise farmers, promote new technology and carry out studies leading to improved farm practice. They also write articles for the local press and organise Farm Demonstrations, Conferences and Farmer Group Meetings. Opportunities exist for appointment at experimental husbandry farms. Ref: S/8642/3

Agricultural Engineering

Successful candidates will provide advice on all mechanisation problems and encourage adoption of improved methods leading to greater productivity. They will, as part of a team, carry out investigations in mechanisation techniques on farms and at Ministry Experimental Centres. Ref: S/8646/3

Horticulture

HAOs advise producers of horticultural crops covering fruit, vegetables, glasshouse crops and hardy ornamentals, bulb and bulb flower crops. They take a special interest in the types of horticulture within their area and in related experimental and development work conducted at Ministry horticulture experimental stations. There are opportunities of appointment to these experimental stations. Ref: S/8644/3

Dairy Husbandry

The work involves technical supervision of the production and handling of milk on farms under the Milk and Dairies Regulations. In addition, advice is given to milk producers on the wider aspects of dairy husbandry. Officers will also assist with surveys and investigations. Ref: S/8643/3

Livestock Husbandry

Officers will specialize to a degree in either Dairy Cattle, Beef Cattle, Sheep or Pig production. They advise farmers and other livestock producers on livestock husbandry, and encourage the adoption of new and improved technology. Also involved is the production of publications for farmers and advisers, and the training of staff. Ref: S/8645/3

Poultry Husbandry

Officers will advise and encourage those in the poultry industry to adopt methods and systems leading to increased productivity. Advisory visits to farms, preparing technical leaflets and local press articles and group discussion meetings. Ref: S/8647/3

Candidates (aged at least 20) should normally have a degree, or equivalent, in a relevant subject. For certain posts an honours degree and some years' experience is required. Ability to drive a car is necessary for most posts.

Salary range £1519-£3895. Starting salary according to qualifications and experience; maximum £3185. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 28 June, 1974) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service), quoting appropriate reference.

(2264)

MINISTRY OF AGRICULTURE, FISHERIES AND FOOD

Graduates

BP Proteins Limited

The Animal Feed Branch of BP Proteins Limited requires two graduates in animal nutrition or a related subject.

The Branch, which is part of the Nutrition function of the Company, is responsible for experimental programmes with the animal feed industry, at research establishments and universities in the United Kingdom and in various other European countries. The Branch also contributes nutritional expertise and services to the Marketing Division as required.

Initially one of those appointed will specialise in the area of poultry nutrition and the other will be concerned with other species, particularly pigs. The principal duties will be to monitor existing projects, collate data from many sources and contribute towards the development of the research programme. A certain amount of travel in the U.K. and Europe will be involved.

Candidates must have up to 5 years' experience in an academic environment or in a research or technical department of an animal feed company. Knowledge of one of the major European languages will be an advantage.

We offer a competitive salary, and other fringe benefits include non-contributory pension scheme, subsidised restaurant and first class social/sports facilities.

■ Please write, giving brief details of age, qualifications and experience, quoting reference U.811, to: The Manager, Central Recruitment, The British Petroleum Company Limited, Britannic House, Moor Lane, London, EC2Y 9BU. (2297)

GOVERNMENT OF FIJI

HYDROLOGIST

Required to control the hydrological organisation of the Public Works Department.

Salary in the range £2,280 to £3,340 p.a. which includes an allowance, normally tax free of £696 to £996 p.a. Generous terminal gratuity.

For a married man with two children paying tax at the standard rate the total emoluments described above, including gratuity, approximate to a gross (i.e. BEFORE TAX) U.K. return of £3,500 to £4,950 and for a single man about £3,300 to £4,750 p.a.

Appointment will be on agreement for 30/36 months initially.
Candidates must have a wide experience ranging over 10 years in general hydrological works, with particular emphasis on the collection and evaluation of rainfall and run-off data, and the location and establishment of hydrological stations.

Other benefits include free passages, liberal leave on full salary, generous education allowances and Government quarters at moderate rental. An appointment grant £200, car advance £600 and packing expenses £60 may be payable.

The post described is partly financed by Britain's programme of aid to the developing countries administered by the Overseas Development Administration of the Foreign and Commonwealth Office.

For further particulars you should apply, giving brief details of experience to

crown agents

M Division, 4 Millbank, London SW1P 3JD, quoting reference number M3B/730217/NF. (2256)

CENTRAL PUBLIC HEALTH LABORATORY
MANAGER—MEDIA PRODUCTION DEPARTMENT

Science graduate (microbiology or biochemistry or pharmacy) required as Manager and to be responsible for day-to-day technical and administrative functions of busy Media Production Department with a staff of 30.

Duties also include, in association with Production Supervisor, supervision of the manufacture of routine and specific media. Good organising ability and a practical nature essential.

Salary according to experience within the National Health Service scale, and at least five years relevant postgraduate experience would qualify a suitable candidate for an appointment in the Senior Scientific Grade of £2,964 to £3,843 per annum, plus £126 London Weighting.

Applications to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (2148)

UNIVERSITY OF EDINBURGH
DEPARTMENT OF BOTANY
POSTDOCTORAL RESEARCH ASSISTANT
PROTEIN CHEMIST/BIOCHEMIST

Applications are invited for the post of Postdoctoral Research Assistant, funded by the Agricultural Research Council, for a period of three years, to work on cell interactions during the development of the graft union in plants, under the direction of Dr. M. M. Yeoman.

Salary within the range £2,025 to £2,346 (under review) with F.S.S.U. benefits.

Applications (2 copies) should be sent as soon as possible to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL. Please quote reference 5023. (2199)

THE UNIVERSITY OF MANCHESTER
RESEARCH ASSISTANT IN THE DEPARTMENT OF CHILD HEALTH

Applications invited from graduates with experience or an interest in cell biology, endocrinology or electron microscopy to work on tissue culture of endocrine pancreas. Appointment for one year in first instance but possibility exists to proceed to Ph.D. for suitable candidate. Salary up to £3,048 p.a. F.S.S.U. Further information and application forms from Dr. R. D. G. Milner, St. Mary's Hospital, Manchester M13 0JH (061-273 3972). (2109)

FLINDERS UNIVERSITY OF SOUTH AUSTRALIA
LECTURER IN HUMAN BIOLOGY

Applications are invited for appointment to the above-mentioned position. A joint Lectureship in the School of Biological Sciences and Medicine has been established and is to be supported by a grant from the Institute of Aboriginal Studies for an initial period of three years, after which it will be funded by the University in the usual way.

The successful applicant must have research interests in the general field of genetics or demography of Australian Aborigines, and will be required to participate in teaching of Human Biology to Science and Medical students.

Informal enquiries may be directed to Professor A. M. Clark, in the University.

Salary Scale: $A8,698 to $A11,982.

Superannuation is on the F.S.S.U. basis.

Further information about the position, including conditions of appointment and details required of applicants, may be obtained from the Secretary-General Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF. Applications should be lodged, **in duplicate**, with the Registrar, The Flinders University of South Australia, Bedford Park, South Australia, 5042, by **June 28 1974.** (2221)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(UNIVERSITY OF LONDON)
DEPARTMENT OF PHARMACOLOGY

Graduate Biochemist required to assist in research on muscle biochemistry. Biochemical experience would be an advantage. The successful candidate will be eligible to register for a higher degree. Starting salary within range £1,200 to £1,300 p.a. Applications should be sent to the School Secretary, 8 Hunter Street, London WC1N 1BP. (2225)

UNIVERSITY OF DURHAM
DEPARTMENT OF CHEMISTRY

Requires a Research Technician to work in the inorganic research group. Applicants should preferably hold a Higher National Certificate, a Final City & Guilds, a Degree or equivalent. Some experience in Chemistry is desirable.

Salary will be at an appropriate point on the University Scale for a Technician (£1,650 to £1,920) according to age, qualifications and experience. Applications in writing giving full details together with copies of two testimonials to the Personnel Office, Science Laboratories, South Road, Durham, by Friday, June 21, 1974. (2226)

UNIVERSITY OF LEICESTER
LECTURER IN BIOCHEMISTRY

Applications are invited for a Lectureship in the Department of Biochemistry (Professor H. L. Kornberg, F.R.S., and Professor W. V. Shaw, M.D.) from October 1, 1974. The Lecturer will teach in the Faculties of Science and Medicine, but preference will be given to applicants whose main experience and research interests are in fields relevant to the newly established Medical School (i.e. "Animal Biochemistry").

The salary scale for this appointment will be according to age and experience on the scale £2,118 to £4,896 a year with F.S.S.U. membership.

Further particulars may be obtained from the Registrar, University of Leicester, Leicester LE1 7RH, to whom applications should be sent by July 1, 1974. (2227)

THE UNIVERSITY COLLEGE OF WALES
ABERYSTWYTH
DEPARTMENTS OF PHYSICS AND CHEMISTRY
POST DOCTORAL RESEARCH ASSOCIATE

Applications are invited for the above post of work on an SRC supported programme on vibrational population distributions of the reaction products of shock-initiated reactions using infra-red spectroscopic techniques. Candidates are expected to hold a suitable Honours degree and have three or more years research experience. Appointment by October 1, 1974, or earlier by arrangement.

Salary: £1,929 to £2,058 plus F.S.S.U.

Further particulars and application forms from the Registrar, The University College of Wales, Aberystwyth. (2228)

UNIVERSITY OF OTAGO
LECTURERS IN BIOCHEMISTRY

Applications are invited, from young graduates, preferably with postdoctoral experience, for two position of Lecturer in Biochemistry. For one of these positions, preference will be given to candidates whose research interests lie in the field of enzyme structure and function.

Salary Scale: NZ$6,753 to NZ$8,568 per annum. Salary scales are subject to both triennial review and cost-of-living adjustments.

Further particulars are available from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or from the Registrar of the University.

Applications close in New Zealand and London on **July 15, 1974.** (2240)

OXFORDSHIRE HEALTH AUTHORITY
(TEACHING)
THE RADCLIFFE INFIRMARY
RENAL BIOCHEMISTRY

Biochemist or Laboratory Technician to collaborate in project on metabolic basis of renal function. Previous laboratory experience essential, experience in enzyme assays helpful. Post financed at present for 18 months (Salary £1,440 to £1,980 p.a.).

Apply in writing to Dr B. D. Rose, Nuffield Department of Clinical Biochemistry, Radcliffe Infirmary, Oxford. Quote ref. 185/74. (2234)

THE UNIVERSITY OF SHEFFIELD
STEROID BIOCHEMIST

Postdoctoral assistant required in the Department of Zoology from a date to be arranged until December 31, 1976 (with possibility of extension to three year appointment) to work with Professor F. J. Ebling on the responses of skin to androgens. Applicants should be chemists or biochemists with experience in field of steroid metabolism in vitro and in vivo. Starting salary £1,929 p.a. with F.S.S.U. provision. Further particulars from the Registrar and Secretary, the University, Sheffield S10 2TN, to whom applications (one copy) should be sent by June 20, 1974. Please quote Ref: R82/G. (2238)

THE GEOLOGICAL SURVEY OF GREENLAND
Geophysicist

A Geophysicist is required for the Geological Survey of Greenland. Candidates should have at least five years' experience in the various branches of oil exploration, geophysics, particularly seismic interpretation, and should have a good command of English. The person appointed will be based in Copenhagen and will be required to undertake periodic field work in Greenland.

The appointment will be on renewable contract and will be pensionable. Applications should be accompanied by a detailed curriculum vitae, an indication of the approximate salary required, and the names of two referees, and should be sent before August 1, 1974 to: The Director, The Geological Survey of Greenland, Øster Voldgade 10, DK-1350 Copenhagen K, Denmark. (2242)

THE ROYAL INFIRMARY OF EDINBURGH
Department of Clinical Chemistry

Applications are invited for the post of basic grade Biochemist. Candidates should have an Honours degree in Biochemistry or Chemistry, or one of the related biological sciences. The post will provide experience of routine hospital service in Clinical Chemistry, and opportunities for engaging in developmental and research work. A training programme exists for preparing basic grade Biochemists for further qualifications in Clinical Biochemistry.

Salary and conditions of service according to current Whitley Council agreements. Applications giving age, qualifications and experience, together with the names and addresses of two referees to Personnel Officer, Royal Infirmary, Edinburgh EH3 9YW by June 21, 1974.

Intending applicants may visit the Department by arrangement with Dr I. W. Percy Robb, telephone 031-229 2477, ext. 2319. (2214)

NATIONAL HEART & CHEST HOSPITALS
Brompton Hospital, London, SW3 6HP

The following vacancies exist in the newly re-organised Department of Pathology. Full training facilities are provided for ONC, IMLT and HNC examinations.

TECHNICIAN OR
JUNIOR TECHNICIAN 'B'
Biochemistry Department

TECHNICIAN
Virology Department

JUNIOR TECHNICIAN 'A'
All Departments

Qualifications required:
Technician — AIMLT or HNC in relevant subject
Junior Technician 'B' — ONC or B.Sc. in relevant subject
Junior Technician 'A' — GCE 'O' level passes in English, Mathematics and two science subjects.

Applications, with the names of two referees to:
F. J. Baker at the above address (2233)

A Professorship (AH 4) in the BIOLOGY FACULTY
of the
UNIVERSITY OF HEIDELBERG

is being re-advertised. The particular orientation in teaching in the sphere of neurosensory, and behaviour physiology should embrace research in one of these fields.

Please apply by letter, including a curriculum vitae, to the University of Heidelberg, 69 Heidelberg 1, Grabengasse 1, by September 30, 1974. (2286)

Ministry of Agriculture, Fisheries and Food
Food Science Division, London

Food Chemist/ Biochemist

■ **Advise on scientific aspects of manufacture and composition of foods and beverages ■ Liaise with other Government Departments ■ Participate in committee work in UK and abroad and in current awareness studies.**

☐ 1st/2nd hons degree in Food Science/Technology or related science ☐ At least 4 years' postgraduate experience in food industry or research on meat, fish, milk or protein foods ☐ Age under 32 ☐ Appointment as Senior Scientific Officer (£3026–£4123 under review) ☐ Ref. SB/8/AE.

Ministry of Agriculture, Fisheries and Food
Fisheries Laboratory, Lowestoft

Biologist

■ **To organise and execute fishery resource surveys using quantative echo-sounding methods.**

☐ 1st/2nd hons degree in Biology or related subject ☐ Understanding of fish population dynamics and working knowledge of underwater acoustics essential ☐ Knowledge of fish behaviour in response to capture and facility with mathematics required ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2221–£2854) or Scientific Officer (£1435–£2329), according to age and experience ☐ Salaries under review ☐ Ref. SB/13/AD.

☐ Application forms (to be returned by 3 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

British Museum (Natural History)

Entomologists

■ **2 posts in Hymenoptera and Trichoptera sections ■ Post One: To carry out taxonomic research on Hymenoptera Parasitica ■ Post Two: To research taxonomy and biology of Trichoptera ■ Supervision of Curatorial work on the National Collection involved in both posts.**

☐ 1st/2nd hons degree or equivalent in Zoology, preferably with Entomology ☐ At least 2 years' postgraduate research experience ☐ Age under 30 ☐ Appointments as Senior Scientific Officer (£3026–£4123) or Higher Scientific Officer (£2449–£3082) depending on age and experience ☐ Salaries under review ☐ Ref. SB/26/DK.

☐ Application forms (to be returned by 3 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Department of the Environment
Building Research Establishment
Princes Risborough Laboratory

Information Scientist

■ **In Application Services Section concerned with disseminating results of research ■ Organise courses, seminars, symposia and visits ■ Arrange presentation of Laboratory's work at exhibitions ■ Liaise with TV and film producers ■ Develop the use of Video Recording Equipment as visual aid.**

☐ Degree/HNC or equivalent in Science or Engineering ☐ Knowledge of timber technology an advantage ☐ Age under 27 ☐ Appointment as Scientific Officer (£1435–£2329 under review) ☐ Ref. SA/63/HA.

☐ Application forms (to be returned by 2 July 1974) from Establishment Office, Princes Risborough Laboratory, Aylesbury, Bucks, HP17 9PX.

Science group
CIVIL SERVICE

(2279)

GEOPHYSICIST

The Lamont-Doherty Geological Observatory of Columbia University announces a position with the seismology group as a Research Associate or Senior Research Associate. Candidates must have a strong background in seismic instrumentation and data analysis and will be expected to lead existing and initiate new programs of research involving observations of earth strain, tilt, and long-period seismic waves. Qualified candidates are invited to submit a résumé of their qualifications, publications, names and addresses of three references by August 15, 1974, to Dr. Lynn R. Sykes, Lamont-Doherty Geological Observatory, Palisades, New York 10964. Columbia University is an equal opportunity employer.

(2260)

TECHNICIAN

with biochemical experience required in Surgical Unit to provide a research analytical service. Commencing salary within scale £1,440 to £1,914 p.a. plus £126 L.W. Apply, The Secretary, St. Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref. SU1. (2255)

CAMBRIDGE UNIVERSITY

DEPARTMENT OF GENETICS

Application are invited from microbial or molecular geneticists for a University Demonstratorship that is expected to be available from October 1, 1974, or sooner.

The scale of stipends from October 1, 1974 will be £2,247 a year rising by annual increments to £2,931 or, if the person appointed is resident in College, £2,148 rising to £2,832.

Further particulars may be obtained from the Secretary of the Appointments Committee of the Faculty of Biology 'A', Department of Applied Biology, Downing Street, Cambridge CB2 3DX, to whom applications should be sent before June 21, 1974. (2254)

UNIVERSITY OF DUNDEE

DEPARTMENT OF PHARMACOLOGY AND THERAPEUTICS

RESEARCH ASSISTANTSHIP

Applications are invited from University graduates or holders of equivalent qualifications for a Research Assistantship in the Department of Pharmacology and Therapeutics, located in the new Ninewells Hospital and Medical School complex, Dundee. The holder of this post, which is available immediately, will be required to provide a Gas-Liquid Chromatographic Service within the Department and to collaborate as required with other staff in research and teaching and will be afforded facilities to carry out his own research work on a part-time basis for a higher degree.

The salary attached to the post will be within the range £1,311 to £2,052 depending on qualifications and experience.

Applicants should apply, giving their qualifications, the names of two referees and quoting Reference Est/39/74J by June 21, 1974 to The Secretary, The University, Dundee DD1 4HN, from whom further particulars may be obtained. (2213)

UNIVERSITY OF HULL
POSTDOCTORAL FELLOWSHIP

Applications are invited for a Postdoctoral Fellowship (SRC) to work in collaboration with Dr R. Aveyard on the effects of electrolytes on aqueous solutions of surface active non-electrolytes. Research experience in thermo-dynamics, physical chemistry of electrolyte solutions, or colloid and surface chemistry would be an advantage.

The appointment which is for two years, is immediately available in the salary range, £2,037: £2,151 per annum rising to £2,226: £2,340 per annum on October 1.

Applications giving details of qualifications, research experience, and the names of two referees should be sent before June 30, 1974, to the Registrar, University of Hull, Hull HU6 7RX, from whom further particulars may be obtained. (2209)

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF PHYSIOLOGY
JUNIOR RESEARCH ASSOCIATE

Junior Research Associate required from September 1974 for one year in the first instance to work on gastrointestinal hormones. Applicants should have or expect to obtain at least a second class degree and have an interest in biochemistry and cell physiology.

Salary scale (effective from October 1, 1974) £1,569 to £1,818 p.a. or the equivalent of a post-graduate grant if registered for a higher degree.

Applications, enclosing curriculum vitae and naming two referees, should be sent as soon as possible and within three weeks of the date of this advertisement to Dr. C. N. A. Trotman, Department of Physiology, The Medical School, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU. (2210)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF BIOCHEMISTRY

A post-doctoral appointment is to be made for research concerned with the control of triglyceride and lipoprotein release from the liver and with the regulation of the enzyme, lipoprotein lipase. Previous experience in either of these areas, or in work on the plasma lipoproteins, would be useful, though not essential.

The research has Medical Research Council support and, though the appointment will be for one year in the first instance, there is provision for extension for up to five years. Salary according to age, qualifications and experience. FSSU benefits will be available. The starting date will be October 1st or as soon thereafter as possible.

Applications, together with the names of three referees and curriculum vitae, should be sent not later than 30 June 1974 to Professor D. S. Robinson, Department of Biochemistry, The University, Leeds, LS2 9JT, from whom further particulars are available. (2237)

UNIVERSITY OF LONDON
CHAIR OF MINERAL TECHNOLOGY AT IMPERIAL COLLEGE

The Senate invite applications for the Chair of Mineral Technology tenable in the Department of Mining and Mineral Technology at Imperial College with effect from October 1, 1974 or as soon as possible thereafter. Initial salary to be agreed but not less than £5,973 plus £162 London Allowance. Applications (10 copies) must be received not later than July 26, 1974 by the Academic Registrar (N), University of London, Senate House, London WC1E 7HU, from whom further particulars should first be obtained. (2222)

UNIVERSITY OF SOUTHAMPTON
FACULTY OF MEDICINE—MICROBIOLOGY

Applications are invited from suitably qualified science graduates for the post of LECTURER IN MICROBIOLOGY. The person appointed will be expected to undertake teaching and research duties in the field of microbial infections. Preference will be given to candidates with an interest in immunochemistry, virology or the chemistry of microbial structure.

Salary scale: £2,118 to £4,896. The initial salary will depend on qualifications and experience. Further particulars may be obtained from the Deputy Secretary's section (Ext. 353), The University, Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should sent not later than June 22, 1974, quoting reference be sent not later than June 22, 1974, quoting 58/74/L. (2249)

ICI Central Toxicology Laboratory

Administrative Assistant

We are looking for a person with a good biological background who will be responsible for the administration and planning of long-term toxicological studies. The work also involves reporting the findings of scientific committees, compiling data and editing technical documents, extensive liaison with staff throughout the Laboratories and a miscellany of administrative tasks necessary for the effective working of a group of 30 laboratory staff.

Applicants should either be graduate biologists or people with experience in laboratory administration. The ability to type would be an advantage.

Applications and enquiries to:

Miss A. Waring
Personnel Officer
ICI Central Toxicology Laboratory
Alderley Park
Nr. Macclesfield, Cheshire SK10 4TJ
Tel: Alderley Edge 2711, Ext. 156

(2248)

Department of the Environment
Building Research Establishment
Princes Risborough Laboratory

Technical Editor

■ **Assist in editing publications** ■ **Draft articles on timber and related technology** ■ **Prepare press releases and liaise with Press** ■ **Arrange dissemination of research results through scientific and technical journals.**

□ Degree/HNC in Science or Engineering □ Editing and technical writing experience and knowledge of timber technology an advantage □ Age under 27 □ Appointment as Scientific Officer (£1435–£2329 under review) □ Ref. SA/62/HA.

□ Application forms (to be returned by 28 June 1974) from Establishment Office, Princes Risborough Laboratory, Princes Risborough, Aylesbury, Bucks, HP17 9PX.

Science group CIVIL SERVICE

(2280)

THE GERMAN CANCER RESEARCH CENTER

REQUIRES

FOR THE INSTITUTE OF IMMUNOLOGY AND GENETICS

QUALIFIED SCIENTISTS

AS HEADS OF THE FOLLOWING GROUPS

I. CELLULAR IMMUNOLOGY	area of research : cell mediated immunity against malignant cells. Experience regarding the following areas would be required : cellular immunity, transplantation immunology and development and growth of tumors.
II. IMMUNOCHEMISTRY	area of research : Characterization of tumor antigens, factors involved in differentiation.
III. IMMUNOGENETICS	Experience regarding the following areas would be required : Histocompatibility antigens, genetic basis of cellular susceptibility to tumor viruses, variability of antibodies, and, genetics of mice. General research area : problems of carcinogenesis.

It is anticipated, that another group "SOMATIC GENETICS", will be established at a later time.

REQUIREMENTS: Recognized scientific ability in the above areas as well as the readiness to cooperate with groups that are already established at the German Cancer Research Center and that are concerned with related subjects.
OFFERS: Salary group AH 3, provided the applicant fulfils the conditions of German Civil Service, or an otherwise appropriate grade of employment. Funds for scientific and technical assistants are available. The space in the institute available for each group will be 300 qm. Facilities including an animal colony, computerised data processing, modern literature search service, central photography laboratory, central spectroscopy laboratory, and central workshop, are available to all scientists at the German Cancer Research Center.

Only written applications will be considered. They should be submitted with a complete list of publications and curriculum vitae to the administration of the "Deutsches Krebsforschungszentrum, D-69 Heidelberg, Kirschnerstraße 6", by September 30, 1974, and should be marked "Berufungsausschuß Immunologie und Genetik".

(2207)

THE UNIVERSITY OF LEEDS
ASTBURY
DEPARTMENT OF BIOPHYSICS

Applications are invited for 3-year post-graduate awards financed by the S.R.C. and M.R.C. for research in the fields of

STRUCTURAL STUDIES OF ENZYMES, POLYSACCHARIDES AND LIQUID CRYSTALS

by means of X-ray diffraction, spectroscopy, chemical sequencing and solution studies.

Candidates are expected to obtain a first or upper second class degree in Physics, Chemistry, Biochemistry or a related subject.

Applications, including the names of two referees, should be sent to Professor A. C. T. North, Astbury Department of Biophysics, The University, Leeds, LS2 9JT. (2236)

THE ROYAL HORTICULTURAL SOCIETY

Applications are invited from graduates in Horticulture or Biological Sciences for the Emmie Clough Scholarship to be awarded by the Royal Horticultural Society for postgraduate research at the R.H.S. Garden, Wisley, Woking, Surrey, on an approved horticultural project.

The scholarship is intended to lead to a higher degree at the University of Reading. Applicants must satisfy the University's entry qualifications, and the research project will be under University supervision.

The subject of research will be approved jointly by the Society and the University and must be concerned with a problem of practical horticultural importance. Possible research topics could be the host relations and control of rusts affecting ornamental plants; sweet pea scorch; the biology and control of lichens. Other topics put forward by applicants will also be considered.

The scholarship of not less than £750/annum is tenable for a period of two years and may be extended.

Applications for the scholarship which will run from October 1974 should include full details of the applicant's experience and qualifications together with the names and addresses of two academic referees and should reach the Secretary, Royal Horticultural Society Offices, Vincent Square, London SW1P 2PE, not later than June 30, 1974. (2253)

SURREY EDUCATION COMMITTEE
EWELL COUNTY TECHNICAL COLLEGE
Reigate Road, Ewell
DEPARTMENT OF BIOLOGICAL SCIENCES

Required as soon as possible

LECTURER 1 OR 2 IN BIOCHEMISTRY

To teach at Higher National Diploma and Certificate and at Membership of the Institute of Biology levels.

An interest in protein biochemistry and the application of physical techniques to biomacro molecules would be an advantage. The successful candidate would also be involved in teaching areas of metabolic biochemistry.

Candidates should have a First Degree in Biochemistry plus industrial and/or reesarch experience. Only those candidates with appropriate teaching experience, in addition to the above, will be considered for the Lecturer 2 grade.

Salary: Lecturer 1—£1,660 to £2,685 p.a.—for Good Honours Graduate the scale is extended to £2,847 p.a.

Lecturer 2—£2,515 by 8 increments to £3,243 p.a.

£118 p.a. London Allowance payable.

Generous relocation expenses and assistance with house purchase in approved cases.

Stamped addressed foolscap envelope, please, for further particulars and application forms from the Vice-Principal. Applications to be returned within 4 days. (2252)

EARTH SCIENCE—QUATERNARY

Applications are invited for a permanent position ubject to availability of funds) effective July 1, 75, at Scarborough College in the University of ronto. Duties—undergraduate instruction in oductory Earth Science and advanced (graduate) ching and research in Quaternary geology or sical geography. Applicants must have a com- ed Ph.D. and postdoctoral experience is pre- d. Salary and rank commensurate with ex- nce. Closing date for applications—January 1, , or when filled. Application, including a com- curriculum vitae and the names of three ees to Dr J. C. Ritchie, Chairman of the h Committee, Scarborough College, University Toronto, 1265 Military Trail, West Hill, rio. (2258)

Cardiovascular Research

Section Head, £4000+

Our cardiovascular teams have proved themselves capable of identifying new approaches to the treatment of heart disease. It is intended that these teams will form the basis of a new section in the department of Pharmacology and Biochemistry.

We need an established pharmacologist, someone with a minimum of 4 years' post-doctoral experience, capable of giving excellent leadership to this section. Good managerial potential is expected since the section will probably expand.

Future growth of cardiovascular research in Fisons will depend largely on your drive and creative ability. A contribution to other fields of drug research will also be expected through interaction with senior scientists in other departments.

Starting salary will be over £4000; benefits, including contributory pension, welfare schemes and expenses towards relocation are excellent.

Please write or telephone for an application form, quoting reference 355R:
John Mills, Personnel Manager, Fisons Limited, Pharmaceutical Division, Bakewell Road, Loughborough, Leics.
Tel: Loughborough 66361

Science Graduates interested in the administration of Medical Research

If you are a Science Graduate with a first or second class honours degree, aged 32 or over, and would like to make a career in the administration of research, a post of Scientific Administrative Officer in the MRC Headquarters Office in London should be of interest to you. Research experience in fields associated with medicine—including social science—and a research degree would be an advantage.

The Medical Research Council is the main Government agency responsible for the promotion of medical research and sponsors an extensive programme, some of which is abroad. The vacant post will be concerned primarily with part of the Council's now clinical activities which includes such subjects as physiology, psychology, genetics, immunology, microbiology and molecular biology. The work will include liaison with members of the Council's scientific staff and others active in the relevant research field and participation in scientific committee and conference activities.

Salary will be in the range of £3,943 to £5,123 per annum, with superannuation provision. Appointments will be to the Council's established staff, subject to satisfactory completion of a probation period of two years.

Application forms may be obtained by writing to or telephoning Mrs. Anne Edwards, Medical Research Council, 20 Park Crescent, London, W1N 4AL. Tel. 01-636 5422 (Ext. 300). Closing date for applications June 26, 1974. Please quote E2/584. (2266)

MRC
Medical Research Coun

TURAL ENVIRONMENT RESEARCH COUNCIL
TITUTE OF GEOLOGICAL SCIENCES

Hydrogeologists

pplications are invited for Senior Scientific Officer, Higher Scientific Officer and ientific Officer vacancies which exist in small teams in the Hydrogeological De- rtment of the Institute, working on basic and applied research projects.

ost 1 Duties are primarily concerned with overseas groundwater modelling projects. Candidates are expected to have a good honours degree or equivalent in Geology or Physics and experience in Fortran programming. Scientific Officer Band I, Higher Scientific Officer Band I, or Senior Scientific Officer.

Post 2 Duties are concerned with overseas hydrogeochemical problems. A good honours degree or equivalent in Geochemistry is required and a background in physical chemistry; some sedimentary or aqueous geochemistry is desirable. Scientific Officer Band I, Higher Scientific Officer Band I, or Senior Scientific Officer.

Post 3 Duties are concerned with hydraulic analysis relating mainly to regional groundwater research studies in the UK. A good honours degree or equivalent in Geology is required while some knowledge of hydraulic engineering or mathematics would be an advantage. Scientific Officer Band I, Higher Scientific Officer Band I, or Senior Scientific Officer.

Posts 4 to 7 Duties are concerned with applied studies overseas. Candidates are expected to have a good honours degree or equivalent in Geology or Environmental Science, with Mathematics or Physics as ancillary subjects. Scientific Officer Band II, Higher Scientific Officer Band I, or Senior Scientific Officer.

Posts 8 and 9 Duties relate mainly to regional research studies in the UK. A degree, HNC or equivalent in Geology or Environmental Science is required; cartographic ability advantageous. Scientific Officer Band III, or Higher Scientific Officer Band II.

For all posts some postgraduate experience in hydrology and/or hydrogeology is desirable.

SALARY (currently under review)

Scientific Officer	£1,663-£2,557
Higher Scientific Officer	£2,449-£3,082
Senior Scientific Officer	£3,026-£4123

Starting salaries may be above the minima.

The staff of the Council are not Civil Servants although their pay and conditions of service are similar to those of scientists in the Civil Service.

Application forms available from Establishment Section, Institute of Geological Sciences, Exhibition Road, London SW7 2DE, quoting Ref. SO/HYD/74/2.

CLOSING DATE FOR RECEIPT OF APPLICATION FORMS JUNE 21, 1974.

(2218)

RESEARCH SCIENTIST (ARMYWORM ECOLOGICAL GENETICIST)
Ref. Res/74/11

Applications are invited from candidates of Ph.D. status to fill the post of Ecological Geneticist in the Armyworm Programme at the I.C.I.P.E. Research Centre.

Responsibilities: The appointee will be required to investigate the ecological genetics of the Armyworm moth, *Spodoptera exempta* (Agrotidae), especially its polymorphism. This must include cryptic polymorphism, ascertained by means of electrophoresis.

Salary: Will depend on qualification and experience, but not less than K.Shs.44,000 per year.

Other benefits include ten per cent gratuity of basic salary earned, a housing allowance, and medical insurance.

Applications, in six copies, should give the following information: General education, Professional qualifications, experience, marital status, age, present salary and terms of service, and names and addresses of four referees (including a personal reference). Photostat copies of relevant transcripts, thesis abstracts, and certificates should be enclosed.

Applications should be addressed to:

The Administrative Officer,
I.C.I.P.E. Research Centre,
P.O. Box 30772,
NAIROBI

to reach him on or before July 1, 1974. (2259)

Kings
HEALTH DISTRICT (TEACHING)
Lambeth, Southwark and Lewisham
Area Health Authority (Teaching)

Research Graduate

Graduate required to work on the Biochemistry of various hormones in women with benign or malignant tumours of the breast.

Application forms obtainable from the Personnel Office, King's College Hospital, Denmark Hill, London, S.E.5. Tel: 01-274 6222 Ext. 2726 (Miss Millwood) should be completed and returned by two weeks after date of insertion. (2251)

UNIVERSITY OF EAST ANGLIA
SCHOOL OF CHEMICAL SCIENCES
RESEARCH IN SPECTROSCOPY

Applications are invited by June 28 for a Postdoctoral Research Associateship available from September 1974 to work with Professor N. Sheppard, F.R.S., on the infra-red spectra of chemisorbed molecules using interferometric techniques. Salary within the range £1,929 to £2,223 p.a., according to age and experience. F.S.S.U. benefits. School of Chemical Sciences, University Plain, Norwich NOR 88C. (2250)

UNIVERSITY OF KENT AT CANTERBURY
RESEARCH POSTS IN MICROBIOLOGY

Applications are invited for the following research appointments in the Biological Laboratory for work on phage and bacterial plasmids.

(a) A Postdoctoral Fellow to work on new methods for determining the kinetics of bacterial growth in infected animals using temperate phage and colicin factors. Salary initially £2,118 in the range £2,118 to £2,412.

(b) A graduate Experimental Officer to assist in physiological and molecular studies on colicin factors. Salary initially £1,686 in the range £1,686 to £1,947.

Microbiological training is essential for both posts and a knowledge of bacterial genetics and its techniques would be an advantage. Application forms and particulars may be obtained from the Assistant Registrar, Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH to whom completed applications should be returned by June 21. Please quote ref. A55/74. (2215)

UNIVERSITY OF SOUTH AFRICA
DEPARTMENT OF MATHEMATICS AND APPLIED MATHEMATICS
VACANCIES FOR SENIOR LECTURER OR LECTURER IN MATHEMATICS AND APPLIED MATHEMATICS OR ASTRONOMY

Applications are invited for the above vacancies. Candidates must state in which topics in one or more of the subjects they have specialised.

Qualified academics are invited to apply to:

The Registrar,
University of South Africa,
P.O. Box 392,
Pretoria,
South Africa.

Applications close on June 30, 1974.

The salary scales are:

Senior Lecturer R6,300 by R300 to R8,100 plus 15%.

Lecturer R4,800 by R300 to R6,900 plus 15%. (2257)

IMPERIAL COLLEGE
DEPARTMENT OF ZOOLOGY AND APPLIED ENTOMOLOGY

Postdoctoral Research Assistant, financed by the S.R.C., required to work on the rôle and nature of insect neurosecretion. Candidates should possess or expect to obtain shortly a Ph.D. and have ability in either Physiology or Biochemistry. The position is for two years and could be taken up as soon as possible. Starting salary £2,094 (under review) including London allowance, with F.S.S.U. A full time Research Technician is available.

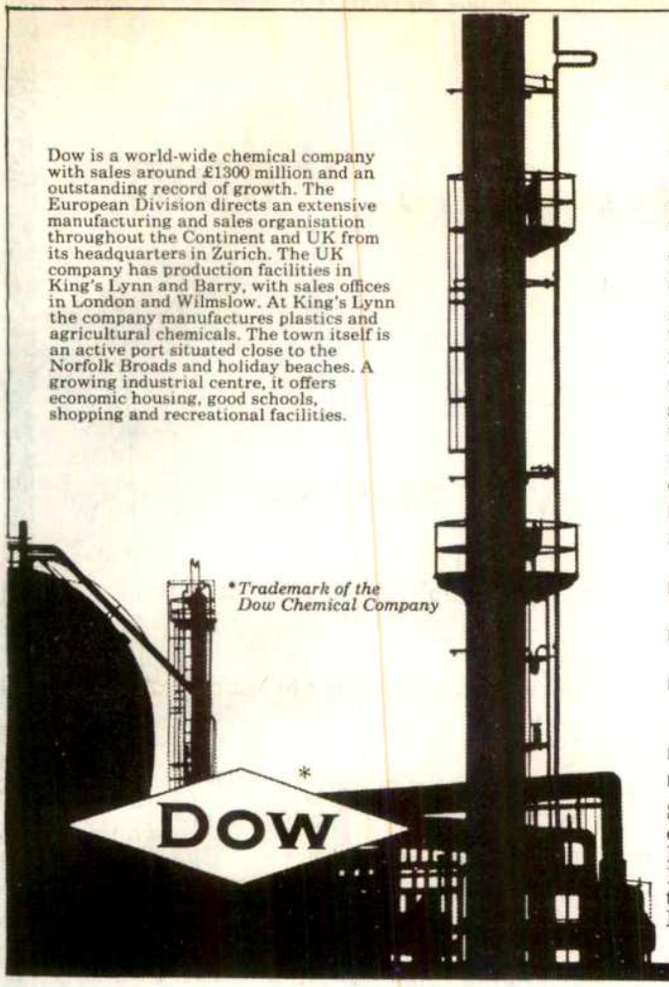
Applications by letter, naming two referees, to Dr W. Mordue, Department of Zoology and Applied Entomology, Imperial College, London, S.W.7, by June 28. (2277)

UNIVERSITY OF SYDNEY
FIXED TERM LECTURESHIP IN THE DEVELOPMENT OF CONTINUING EDUCATION IN VETERINARY SCIENCE

Applications are invited for the abovementioned position. The appointee will be involved in the development of continuing education in Veterinary Science and will be expected to work in close liaison with the Postgraduate Committee in Veterinary Science and other appropriate scientific bodies.

The initial appointment will be for two years with the possibility of an extension beyond that period.

Salary: $A8,698 to $A11,982 p.a.



Further information available from the Dean of the University. Applications including curriculum vitae, list of publications and names of three referees to the Registrar, University of Sydney N.S.W. 2006, Australia, by **June 28, 1974,** or as soon as possible thereafter. Information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1 0PF. (2220)

FEDERAL INSTITUTE OF TECHNOLOGY
ZÜRICH, SWITZERLAND

Applications are invited from physical chemists for the position of postdoctoral research assistant to work with Prof Urs P. Wild in the field of photochemical and photophysical primary processes. Experience in the field is required. The appointment will be for 1 year, renewable for a second year, commencing not later than October 1974. Salary sfr. 30,000 per annum.

Detailed application including curriculum vitae, list of publications, and names of three referees should be addressed to:

Prof Urs P. Wild,
Physical Chemistry Laboratory,
Universitätstrasse 22,
CH-8006 Zürich, Switzerland. (2

Dow is a world-wide chemical company with sales around £1300 million and an outstanding record of growth. The European Division directs an extensive manufacturing and sales organisation throughout the Continent and UK from its headquarters in Zurich. The UK company has production facilities in King's Lynn and Barry, with sales offices in London and Wilmslow. At King's Lynn the company manufactures plastics and agricultural chemicals. The town itself is an active port situated close to the Norfolk Broads and holiday beaches. A growing industrial centre, it offers economic housing, good schools, shopping and recreational facilities.

*Trademark of the Dow Chemical Company

Entomologist

for Products Screening

to join our recently formed and rapidly expanding Agricultural Research Centre in King's Lynn.

At the Centre, Dow's first major research establishment outside the USA, we are looking for screening specialists to play a key role in its future growth.

Their initial task will be to develop a systematic approach to screening for biologically active compounds, leading eventually to the function of Product Specialist Insecticides.

Candidates, male or female, should have the following qualifications:

- University degree, preferably Ph.D. in Entomology.
- Extensive experience in screening of biologically active compounds.
- A wide knowledge of the crop insecticide markets and their requirements, particularly in the area Europe/Africa.
- A good basic knowledge of organic and biochemistry and of structure-activity relationships.
- Experience in organising biological screens and experience in developing and maintaining laboratory cultures and colonies.
- Experience of working in Continental Europe.
- Fluency in a European language, other than native tongue.

Starting salary will be negotiable depending on experience and qualifications. Benefits include contributory pension scheme, BUPA membership and comprehensive removal allowances. Please write for an application form, quoting reference U.166, to: A. Clapham, UK Personnel Manager, Heathrow House, Bath Road, Hounslow TWS 9QY.

(2247)

RESEARCH TECHNICIAN

required to assist in exciting current project in an expanding field of research for the development of suitable in vitro immunological techniques related to the understanding and treatment of allergy. Salary on Whitley Council scales. Enquiries and applications in writing stating age, qualifications, experience and names of two referees to Mr K. C. Huggins, Department of Immunology (N), The Middlesex Hospital Medical School, Arthur Stanley House, 40/50 Tottenham Street, London W1P 9PG. (2274)

QUEEN ELIZABETH COLLEGE

(UNIVERSITY OF LONDON)
CAMPDEN HILL ROAD, W8 7AH

Applications are invited for the post of Lecturer in the Microbiology Department. Candidates should be postdoctoral or about to complete Ph.D. thesis; they should be active research workers and versatile as teachers. Further particulars from the College Secretary (N), to whom applications should be sent by July 1. (2275)

RESEARCH ASSISTANT

Applications are invited for a Research Assistantship to work on problems concerned with mammalian fertilisation. Applicants should be of at least graduate status with an interest in the physiology and biochemistry of reproduction. The appointment would be for one year in the first instance with the possibility of an extension for a further two years. Salary around £1,850 plus F.S.S.U.

A curriculum vitae and names of two referees should be sent immediately to Dr D. B. Morton, Strangeways Research Laboratory, Worts Causeway, Cambridge CB1 4RN. (2282)

REQUIRED

Female Graduate Geologist with secretarial training. Good shorthand and typing necessary as well as ability to assess and assemble scientific material. Apply: Personnel Officer, Robertson Research International Limited, Ty'n-y-Coed, Llanrhos, Llandudno LL30 1SA, Caernarvonshire, North Wales. (2283)

DUBLIN INSTITUTE FOR ADVANCED STUDIES

SCHOOL OF COSMIC PHYSICS

Applications are invited from persons suitably qualified in the field of Solid Earth Geophysics for a permanent appointment in the Geophysical Section of the School of Cosmic Physics.

Appointment will be made at the level of either Professor or Assistant Professor.

Salary scales: Professor, £4,185 by £188(3) by £187 to £4,936; Assistant Professor, £3,092 by £123(6) by £128 to £3,958. (Both scales under review at present).

Applications, accompanied by a curriculum vitae, list of publications and the names of two referees, should be sent so as to reach the undersigned (from whom further particulars may be obtained) on or before July 8, 1974.

The Registrar,
Dublin Institute for Advanced Studies,
10 Burlington Road,
Dublin 4. (2278)

THE FREE UNIVERSITY OF BERLIN

has an opening at the Assistant Professor level for a MEMBRANE BIOCHEMIST with interests in the membrane transport of yeasts.

The appointment will be for four years (salary about 30,000 DM per annum) commencing to August 1, 1974, or later.

Demands are experience in the isolation and characterisation of cell membranes as well as a good knowledge in biochemical methods. The candidate agrees to perform courses on problems of biochemistry and molecular biology.

Applications giving full details of education and qualifications should be sent within four weeks after publication of this advertisement to Dr Uwe Reichert, Freie Universität Berlin, Zentralinstitut für Biochemie und Biophysik, D-1000 Berlin 33, Ehrenbergstraße 26-28. (2291)

CENTRAL BIRMINGHAM HEALTH DISTRICT

THE CHILDREN'S HOSPITAL

PRINCIPAL AND SENIOR GRADE BIOCHEMIST

The Clinical Chemistry Department at the Children's Hospital gives a Regional Paediatric service and offers experience in a wide range of Biochemical techniques, including screening and research into inherited metabolic disease. The appointment of the successful candidate will depend on previous hospital experience, qualifications, and ability to deputise for the Consultant Chemical Pathologist.. Salary:

Principal £3,969 to £5,175.

Senior £2,964 to £3,843.

For further information please contact Dr D. N. Raine (telephone 021-454 4851), to whom applications giving personal details and the names of two referees should be sent. The Children's Hospital, Ladywood Middleway, Fiveways, Birmingham B16 8ET. (2267)

IMPERIAL COLLEGE

DEPARTMENT OF ELECTRICAL ENGINEERING
ENGINEERING IN MEDICINE LABORATORY

BIOLOGICAL SIGNAL ANALYSIS

A Postdoctoral RESEARCH ASSISTANT to Professor B. McA. Sayers is required for a continuing research programme supported by the Medical Research Council, on the exploratory analysis of signals of neural, physiological, clinical, or epidemiological origin.

Candidates should have a Ph.D. and a good knowledge of computer programming, and preferably be familiar with signal analysis techniques. The appointment will be initially for one year, renewable annually subject to satisfactory progress up to a maximum period of 5 years. The starting salary is up to £2,385 including London allowance (under review) depending on age and experience, and carries membership of F.S.S.U. Applications, with the names of two referees, should be sent to The Secretary, Engineering in Medicine Laboratory, Department of Electrical Engineering, Imperial College, SW7 2BT as soon as possible. Tel. 01-589 5111, Ext. 1409. (2276)

vrije universiteit amsterdam

The Netherlands

The Central Interfaculty of Philosophy has a vacancy for a full

professor of philosophy of science

who should be qualified in the physical sciences and in philosophy and is expected to have a doctor's degree in one of the two.

He should give lecture courses on philosophy of science in general and philosophy of the physical sciences in particular and conduct research in this field.

Teaching and research will be mainly in the Faculty of Mathematics and Natural Sciences, which has departments of mathematics, physics, chemistry, geology and biology and numbers appr. 30 full professors and 1.750 students.

The Central Interfaculty numbers 10 professors and 150 students.

The Free University was founded as a private non-denominational Christian Institution and is now a fully state subsidized private university. The preamble to its charter speaks of the Christian idea of service, in obedience to the Gospel of Jesus Christ, as the University's guiding principle. It will be appreciated if candidates would express their attitude towards this principle in their application.

Gross salary offered: about D.fl. 95.000,- per annum.

Both applicants and those who would like to draw the attention to possible candidates are requested to write within two months from the appearance of this issue to the Chairman of the appointment committee, Dr. J. v.d. Hoeven, Central Interfaculty, Vrije Universiteit, De Boelelaan 1105, Amsterdam, The Netherlands.

Candidates should mention referees when applying.

(2261)

THE HANNAH RESEARCH INSTITUTE

DEPARTMENT OF APPLIED STUDIES

CARBOHYDRATE BIOCHEMISTRY

Applications are requested from persons having experience of carbohydrate biochemistry to assist with work on the starch-degrading enzymes of bovine serum as an index of genetic potential. The appointment will be made at the H.S.O. level (£2,221 to £2,854, with an allowance of 5½% to offset superannuation contributions); applicants should possess an honours degree and a minimum of two years' relevant postgraduate experience. Applications, giving a full curriculum vitae and the names of two referees, should be sent to the Secretary, The Hannah Research Institute, Ayr KA6 5HL to whom further particulars may be obtained from by June 21, 1974. (2284)

UNIVERSITY OF TORONTO

INSTITUTE OF BIOMEDICAL ENGINEERING

DIRECTOR

Applications are invited for the above position in Ontario, Canada. The applicant should have distinction as an investigator in the biological engineering field, with academic experience, leadership, and administrative ability. The Director of the Institute will also be appointed to appropriate Departments in Engineering and/or Medicine.

Nominations and applications should be directed to the Chairman of the Search Committee, Professor B. Etkin, Faculty of Applied Science and Engineering, University of Toronto, Toronto, Ontario, Canada.

(2290)

Ph.D. PSYCHOLOGIST

Ph.D. Psychologist to be responsible for carrying out specific phases of research with nonhuman primates. The applicant should be competent in telestimulation and telemetry of discrete brain areas, have a thorough knowledge of the neuroanatomy of Macaca speciosa, experience in the recording of single unit activities in the awake animal, and must know how to suppress stimulus artifacts. Other duties involve biochemical assays of perfusates obtained from push-pull cannula and iontophoretical studies of neuronal activities in CNS.

Assistant Professor level. Send applications to Professor James Maas, Department of Psychiatry, Yale University School of Medicine, 333 Cedar Street, New Haven, Ct., 06510, U.S.A.

AN EQUAL OPPORTUNITY EMPLOYER

(2285)

POLYTECHNIC OF THE SOUTH BANK
DEPARTMENT OF PHYSICS
GRADUATE SCIENTIFIC ASSISTANT

Applications are invited for a Graduate Scientific Assistant to work with Dr Haque on an M.R.C. supported project to study the radiation dose to the respiratory system due to radon and its daughter products using experimental and computer methods. Candidates should possess a good Honours degree in Physics or equivalent qualifications and preferably postgraduate experience. The successful applicant may register for a Ph.D. degree.

Salary offered is up to £1,400 per annum, depending on age and experience.

Applications by letter, naming two referees, should be sent to the Secretary, Physics Department, Polytechnic of the South Bank, Borough Road, London SE1 0AA, from whom further particulars may be obtained. (2268)

UNIVERSITY OF LONDON GOLDSMITHS' COLLEGE
NEW CROSS, LONDON SE14 6NW
CHEMISTRY DEPARTMENT

Required, as soon as possible, Lecturer in Chemistry with good academic qualifications, able to teach inorganic and/or physical chemistry up to B.Ed. and B.Sc. Standard II.

Salary on Pelham scale for teaching staff in College of Education, plus London Allowance.

For further particulars write, enclosing a stamped addressed A4 envelope, to the Personnel Officer, to whom applications should be sent by June 14, 1974. (2263)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
DEPARTMENT OF BIOCHEMISTRY
POSTGRADUATE RESEARCH

Research activities open to graduates wishing to work for the M.Phil. or Ph.D. degree include:

Yeast viruses: host-virus relationships.

Mycoviruses: characterisation and biochemistry of virus replication cycle.

Grants will be available to suitable candidates.

Enquiries should be made to:

Dr K. W. Buck,
Department of Biochemistry,
Imperial College,
London SW7 2AY. (2262)

INSTITUTE OF ARCHAEOLOGY
UNIVERSITY OF LONDON

Lecturer/Senior Lecturer in Archaeological Conservation. Salary within the scale £2,118 to £5,844. The person appointed will be required to organise teaching and research relating to the conservation of archaeological materials, in which subject new First Degree and Higher Degree courses are being established. Qualifications should include a good Honours Degree in a science subject (preferably Chemistry). Practical experience in the techniques of archaeological conservation would be an asset. The successful applicant will be expected to take up his post on, or as soon as possible after, October 1, 1974. Applications (2 copies) giving full details of qualifications, experience and publications should reach the Director, University of London Institute of Archaeology, Gordon Square, London WC1H 0PY by June 30, 1974. (2292)

UNIVERSITY OF THE SOUTH PACIFIC
FIJI

Applications are invited for LECTURESHIP IN CHEMISTRY in the School of Natural Resources, tenable from the beginning of 1975. Applicants should have interests in Inorganic Chemistry and should have a strong motivation to developing courses appropriate to the South Pacific context. Teaching duties will be assigned by the Head of Chemistry and may be at all levels of the B.Sc. course. Research involving the natural resources of the Region is encouraged and there are unique opportunities in areas such as Marine Chemistry and Soil Science. Salary scale (under review): $F4,700 to $F6,500 p.a. (£1 sterling = $F1.94). 10% annual gratuity for contract appointment; superannuation contributions; partly furnished accommodation at rental of 15% of salary; appointment allowance. Contracts may be for two, four or six years. Formal applications (6 copies) should contain full name, date and place of birth, nationality, marital status, educational qualifications, employment history and experience, names and addresses of three referees, general statement of physical fitness, estimated starting date. A passport-size photograph should also be sent. Further particulars, including an outline terms of service, are available from the Registrar (Post 74/16), University of the South Pacific, P.O. Box 1168, Suva, Fiji. Closing date: as soon as possible. (2306)

Agro Chemical Formulation

Development of our activities has created the need for a graduate to work in our Development Laboratories concerned with Animal health, pet, crop protection and amateur garden products. The position, tenable at Beeston near Nottingham, involves the design and investigation of formulations, including appropriate stability testing. Particular emphasis will be placed on investigational work.

Applications are invited from graduates in Chemistry, Pharmacy or an allied subject and although experience in Product Development would be an advantage it is not essential.

Conditions of employment are first class. Some help with relocation expenses will be given where appropriate.

Please write for application form, quoting ref. U.198, to J. F. Pattison, Employment Manager.

THE GEOLOGICAL SURVEY OF GREENLAND
Stratigrapher/Palynologist

A position is available in the Oil and Gas Section of the Geological Survey of Greenland for a geologist with a background in stratigraphy and in particular palynology. The successful candidate will be required initially to work on Mesozoic-Tertiary sediments of central West Greenland, but will later assist in building up knowledge of the West Greenland shelf on the basis of deep well samples.

The person appointed will be based in Copenhagen and will be required to undertake periodic field work in Greenland.

Applications should be accompanied by a detailed curriculum vitae, and indication of the approximate salary required, and the names of two referees, and should be sent before August 1, 1974, to: The Director, The Geological Survey of Greenland, Oster Voldgade 10, DK-1350 Copenhagen, Denmark. (2243)

Graduate Required

Physics/Chemistry Graduate required for interesting research post within our Central Laboratories Division. The job is concerned with the creepage along and wetting of metal surfaces by liquids. The position is new and offers excellent scope for originality and innovation.

Undergraduates qualifying this year will be considered.

Research facilities and future prospects are good.

Location: North London.

Hours: 9 am to 5.15 pm (Mon to Fri) 36¼ hr. week.

Apply:

EVER-READY®

Administration Manager,
Ever Ready (Holdings) Limited,
Central Laboratories,
St. Ann's Road,
London, N15 3TJ. Tel. No. 01-800 1101. (2244)

Beecham Pharmaceuticals

Biochemist

A Biochemist is required for the Fermentation Development Department to investigate the metabolic control of penicillin production.

Ideally applicants should be post doctoral workers with experience of the biosynthesis of secondary metabolites or the control of metabolic pathways, although a good new graduate with a keen interest in these areas could be considered. Excellent facilities exist for studying Laboratory, Pilot Plant and large-scale production fermentations.

We offer competitive salaries, four weeks holiday, excellent Sport and Social facilities and an attractive South Coast location. Benefits also include a non-contributory pension and life assurance scheme.

Please write giving brief details of age, qualifications and experience to Miss C. Turnbull, Personnel Officer, Beecham Pharmaceuticals, Clarendon Road, Worthing, Sussex.

THE QUEENS AWARD TO INDUSTRY 1966 1970 1971 1972.

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

MILL HILL, LONDON

ELECTRON MICROSCOPY TECHNICIAN

familiar with thin tissue sectioning is required to assist in the examination of cells and sub-cellular components during animal development. Experience in electron microscopy would be an advantage. Initial salary, according to age, qualifications and experience, will be on scales £1,566 to £2,418 p.a. or £2,202 to £2,949 p.a. Please write, quoting ref. EM/DB to J. H. Woodcock, Personnel Officer, N.I.M.R., The Ridgeway, Mill Hill, London NW7 1AA. Tel: 01-959 3666. (2232)

BIRKBECK COLLEGE
(UNIVERSITY OF LONDON)
DEPARTMENT OF ZOOLOGY
M.Sc. DEGREES FOR PART-TIME STUDENTS
IN
ENTOMOLOGY
AND IN
COMPARATIVE PHYSIOLOGY

Each Course extends over a period of two calendar years and involves attendance on three evenings each week during term. Examination is by written papers and course assessment.

Full details may be obtained from The Secretary, Department of Zoology, Birkbeck College, Malet Street, London WC1E 7HX, to whom application should be addressed. (2293)

WYE COLLEGE
(UNIVERSITY OF LONDON)
PLANT BREEDER

Applications are invited for a temporary appointment as Assistant Plant Breeder in the Hop Research Department.

The Department undertakes research on most aspects of the hop crop and the plant breeding section is engaged in meeting the urgent needs of the industry for varieties of improved brewing value combined with disease and pest resistance.

The successful applicant will be expected to assist with all aspects of the breeding programme but to concentrate on the nature and inheritance of disease and pest resistance and to undertake some cytological work. There will be every opportunity for undertaking a higher degree.

The appointment will be in the S.O. (£1,707 to £2,329) or H.S.O. (£2,221 to £2,854) grade according to experience, and will be for four years. There will be a non-pensionable allowance of 4½% of gross salary to offset contributions to the Superannuation Scheme operated under the F.S.S.U.

Candidates should have, or expect to have, a good Honours degree but postgraduate experience is not essential.

Applications, naming two referees to the Secretary (N), Wye College, Wye, Ashford, Kent TN25 5AH, by June 30, 1974. (2294)

UNIVERSITY COLLEGE, CARDIFF

RESEARCH ASSISTANTSHIPS IN THEORETICAL ASTRONOMY

Applications are invited from suitably qualified candidates for two S.R.C. Research Assistantships: one for work on Relativistic Astrophysics and one for work on Interstellar and Intergalactic Grains. Salary Range: £2,118 to £2,247. Duties to commence as soon as possible. Closing date is two weeks from the appearance of this advertisement.

Applications, together with the names and addresses of two referees, should be forwarded to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Please quote ref. 0582. (2288)

UNIVERSITY OF IBADAN
NIGERIA

Applications are invited for the following posts in the DEPARTMENT OF AGRICULTURAL ECONOMICS AND EXTENSION:—

1. SENIOR LECTURER IN RURAL DEVELOPMENT AND AGRICULTURAL POLICY. Applicants should be Agricultural Economists with emphasis on Rural Development and Agricultural Policy. They should have a Ph.D. in Agricultural Economics with a sound background of economic theory and its application to rural development and agricultural policy. They should also possess proven ability to undertake and direct comprehensive research in rural integrated development.

2. SENIOR LECTURER IN AGRICULTURAL PRODUCTION ECONOMICS AND ECONOMETRICS. Applicants should specialise in the field of Agricultural Production Economics and Econometrics. They should have a Ph.D. with a major in Production Economics and a minor in Agricultural Statistics and/or Econometrics. The appointee should be able to supervise experimental designs for graduate research in the Faculty.

Salary scale: N5,030 to N5,750 p.a. (£1 sterling =N1.47). The British Expatriates Supplementation Scheme is unlikely to be applied to these appointments. F.S.S.U. Family passages; various allowances; regular overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than 1st July, 1974, to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars of these appointments may be obtained from either address. (2312)

UNIVERSITY OF KHARTOUM
SUDAN

Applications are invited for (a) READERSHIP or (b) SENIOR LECTURESHIP IN THE DEPARTMENT OF PHARMACEUTICS. This post is tenable for one year only. Salary scales: (a) £S3,000 p.a. (b) £S2,400 to £S2,800 p.a. (£1 sterling=£S0.77). The British Government (or similar arrangement may be made) may supplement salary of Senior Lecturer by £1,600 p.a. (sterling) for married appointee or £900 p.a. (sterling) for single appointee (normally free of all tax). The supplementation for Reader's salary will be determined when an appointment is made at that level. These supplementation rates are currently under review. There may also be provision of children's education allowances and holiday visit passages. Family passages; various allowances; superannuation scheme; annual overseas leave. Detailed applications (2 copies), including a curriculum vitae nd naming 3 referees, should be sent by air mail, not later than June 27, 1974 to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. (2305)

UNIVERSITY OF KHARTOUM
SUDAN

Applications are invited for the post of SENIOR TECHNICIAN IN THE DEPARTMENT OF PHYSIOLOGY. Candidates should hold A.I.M.L.T. Salary scale: £S1,250 to £S1,500 p.a. (£1 sterling=£S0.77). The British Government may provide a supplement to the salary, the amount to be determined when an appointment is made. This supplementation is normally free of all tax. There may also be provision of children's education allowances and holiday visit passages. Family passages; various allowances; superannuation scheme; annual overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than June 27, 1974 to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (2304)

NEW ZEALAND
UNIVERSITY OF CANTERBURY
CHRISTCHURCH
VISITING LECTURER IN CHEMISTRY

Applications are invited for a Visiting Lectureship in Chemistry tenable for one year. The appointment is to be taken up as early as possible in 1975. It is anticipated that the appointee will have completed a Ph.D., and show evidence of strong research interest in some particular field of Chemistry. The emolument for the position is in the range of NZ$6,753 to NZ$8,568 per annum. (Subject to regular cost of living adjustments.) When the salary is being decided, due account will be taken of the appointee's travel costs.

Further particulars and Conditions of Appointment may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London, WC1H 0PF.

Applications close on **September 1, 1974.** (2311)

UNIVERSITY OF OTAGO
DUNEDIN, NEW ZEALAND
LECTURER OR SENIOR LECTURER IN PHYSIOLOGY

Applications are invited from Medical or Science Graduates for appointment as Lecturer or Senior Lecturer in Physiology. Preference will be given to candidates with experience in renal and electrolyte physiology, but those with interests in other fields will be considered.

Medical Graduate: Lecturer—A scale from NZ$9,172 to NZ$13,107 per annum with a bar at NZ$10,836 per annum; Senior Lecturer—A scale from NZ$13,485 to NZ$15,528 per annum.

Science Graduate: Lecturer—A scale from NZ$6,753 to NZ$8,568 per annum; Senior Lecturer—A scale from NZ$8,718 to NZ$11,139 per annum.

Further information may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University. Additional detailed information may be obtained from Professor J. R. Robinson, Department of Physiology, University of Otago Medical School, P.O. Box 913, Dunedin, New Zealand.

Applications close in London and in New Zealand on **July 31, 1974.** (2308)

SWISS FEDERAL INSTITUTE OF TECHNOLOGY, ZURICH (SWITZERLAND)
(EIDGENÖSSICHE TECHNISCHE HOCHSCHULE)

Professor of Experimental Nuclear Physics

Applications are invited for the above appointment which is to commence on April 1, 1975 or by arrangement. The professor will be expected to carry out teaching and research in experimental nuclear physics and to take part in the general teaching programme of the Physics Department.

Candidates are requested to send their applications with curriculum vitae, and list of scientific publications (and names of references) not later than June 30, 1974 to: The President, Eidgenössische Technische Hochschule Zürich, CH-8006 Zürich/ Switzerland. (2216)

Australian Academy of Science

Executive Secretary

The present Executive Secretary of the Australian Academy of Science, Mr J. Deeble, shortly takes up the post of Director of Special Projects. The Academy therefore invites applications for the post of Executive Secretary. The appointee will be responsible to the Council, through its Officers, for the conduct of the business of the Academy. Applicants should have a background in science and ability and experience in administration. General information is available from the Year Book of the Academy. Supplementary information will be furnished by the Secretaries on application to the address below.

Salary will be in the range Reader to Professor in Australian Universities (currently $A16,389 to $A19,614 per annum).

Applications should be forwarded to the **Secretaries, Australian Academy of Science, P.O. Box 821, Canberra City, A.C.T. 2601, Australia.** They should include a detailed curriculum vitae and the names of at least three referees. The closing date is **July 5, 1974.** (2322)

ST. MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Paddington, London W2 1PG

Applications are invited from candidates with 1st or 2nd Class Honours Degree in Biochemistry or related discipline wishing to work for a Ph.D. for three studentships for training in research methods in Pharmacological Biochemistry. These awards will be governed by the M.R.C. regulations. Apply with curriculum vitae and names of two referees to Professor R. T. Williams, Department of Biochemistry. (2326)

WESTFIELD COLLEGE
(UNIVERSITY OF LONDON)
LECTURESHIP IN ZOOLOGY

Applications are invited for a lectureship in the Zoology Department which it is anticipated will become established with effect from October 1, 1974. The post will be for three years in the first instance and an appointment will be made on one of the three lowest points on the lecturer scale £2,118, £2,247, or £2,412 plus £162 London Allowance. Applicants should have an experimental approach involving the study of whole animals in relation to their environment & should be capable of contributing to the teaching programmes in Cell-Biology or environmental science. Applications (6 copies) should be sent as soon as possible and not later than **June 18, 1974,** giving the names of two referees to Dr J. Buckingham, Personnel Officer, Westfield College (N), Kidderpore Avenue, Hampstead, London NW3 7ST. **Applicants quoting overseas referees should ask them to submit references immediately and without further intimation.** (2302)

UNIVERSITY OF KHARTOUM
SUDAN

Applications are invited for the following posts in the Department of Clinical Studies, Faculty of Veterinary Science:—

1. SENIOR LECTURER OR LECTURER IN VTERINARY OBSTETRICS AND GYNAECOLOGY. Candidates should hold a first in Veterinary Medicine and a higher degree in Obstetrics and Gynaecology, and have at least three years' teaching and practical experience. Appointee will teach Veterinary Obstetrics and Gynaecology to students and participate in hospital work and research.

2. SENIOR LECTURER OR LECTURER IN VETERINARY SURGERY. Candidates should hold a higher degree in Veterinary Surgery and at least two years' teaching experience at university level. Duties will be: teaching Veterinary Surgery, including Anaesthesia, to final and subfinal year students; doing research in the Department; supervision of postgraduate students for higher degrees; participation in clinical and surgical work in connection with the University Veterinary Clinic.

Safary scales: Senior Lecturer £S2,400 to £S2,800 p.a.; Lecturer £S1,500 to £S2,300 p.a. (£1 sterling=£S0.77). The British Government may supplement salaries in range £1,300 to £1,600 p.a. (sterling) for married appointees or £800 to £900 p.a. (sterling) for single appointees (normally free of all tax) and provide children's education allowances and holiday visit passages. These supplementation rates are currently under review. Family passages; various allowances; superannuation scheme; annual overseas leave. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than June 27, 1974 to the Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (2303)

MASSEY UNIVERSITY
PALMERSTON NORTH, NEW ZEALAND
SENIOR LECTURER/LECTURER IN VETERINARY PUBLIC HEALTH AND MEAT HYGIENE

Applications are invited from veterinary graduates for this new post in the Department of Veterinary Pathology and Public Health. Applicants should have an interest in this challenging and increasingly important sphere of veterinary science. Although experience in some facet of this discipline, which includes meat hygiene as an important component, is desirable, a recent graduate would be considered. Such a latter appointment would be in the lower scale of the lecturer range and the appointee would be given the opportunity to undertake further study.

The successful applicant will be required to assist in the teaching of veterinary public health and meat hygiene to both undergraduate and postgraduate students, and to develop research in appropriate fields of study. The position involves close cooperation with workers in related disciplines both within and outside Massey University. The particular interests of the department include basic epidemiology, meat hygiene and food born diseases and all aspects of zoonoses and general public health.

Present salary scales are: Lecturer NZ$6,753 to NZ$8,568; Senior Lecturer NZ$8,718 to NZ$10,232 (bar) $NZ11,139.

Further details of the position and of the University, together with the general conditions of appointment may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on **July 15, 1974.** (2309)

THE BRITISH NUTRITION FOUNDATION

An independent advisory and grant-giving body, invites applications from graduates in Food Science or Technology or Nutrition for the post of Scientific Information Officer. Salary negotiable, but up to £2,750 depending on experience. Particulars of the duties may be obtained from the Director-General of The British Nutrition Foundation, Alembic House, 93 Albert Embankment, London SE1 7TY, by whom applications, including particulars of career and the names and addresses of two referees, should be received not later than June 28, 1974. (2300)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for the following:

RESEARCH SCHOOL OF SOCIAL SCIENCES
RESEARCH FELLOW
DEPARTMENT OF STATISTICS

The successful applicant will be expected to engage in research in probability and statistics. The interests of present members of the department are in time series, gometrical probability, random processes and statistical inference. Head of the Department is Professor P. A. P. Moran. Closing date: **July 5, 1974.**

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES
DEPARTMENT OF DEVELOPMENTAL BIOLOGY

Appointees to the following posts will work in a research group headed by Professor Brian Gunning.

RESEARCH FELLOW

The proposed field of study is the analysis of developmental processes in plant cells, especially algae, using ultrastructural methods in conjunction with additional experimental approaches.

RESEARCH ASSISTANT

Applicants should have a degree in a life science, an interest in plant cell biology, and preferably some experience of electron microscopy. The work will involve assistance in the work of the group by means of laboratory and library research. Closing date: **July 12, 1974.**

Salaries: Salary on appointment to the posts will be in accordance with qualifications and experience within the ranges: Research Fellow $A8,698 to $A11,901 p.a.; Research Assistant Grade 1 $A4,394 to $A6,250 p.a.; Research Assistant Grade 2 $A6,247 to $A7,846 p.a. Current exchange rates are approximately $A1=$US1.49.

Other Conditions: Tenure: Research Fellow normally for three years in the first instance with the possibility of extension to a maximum of five years; Research Assistant initially for a period of two years.

Reasonable travel expenses are paid and assistance with accommodation is provided for an appointee from outside Canberra. Superannuation (where applicable) is on the F.S.S.U. pattern with supplementary benefits.

Travel expenses from overseas (except New Zealand) are not paid for posts at the level of Research Assistant but assisted passage can be considered for a person offered appointment from the United Kingdom who intends to settle permanently in Australia.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before applying. (2310)

UNIVERSITY OF EAST ANGLIA
SCHOOL OF CHEMICAL SCIENCES

Applications are invited for a S.R.C. Post-Doctoral Research Assistantship for one year in the first instance from 1 October 1974, to work on the magnetic circular dichroism of matrix-isolated molecules. A novel apparatus for this purpose has recently been constructed and is now operational. The investigation is to be extended to the study of the magnetic and optical properties of unstable molecules generated photochemically. Salary will be on a scale starting at £1929 per anunm plus F.S.S.U., according to previous experience.

Applications as soon as possible either to Dr. R. Grinter or Dr. A. J. Thomson, School of Chemical Sciences, University of East Anglia, Norwich, NOR 88C. (2296)

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF NATURAL PHILOSOPHY
LECTURESHIP

Applications are invited from experimental physicists preferably with research experience in plasma/laser physics.

The successful candidate will be required to take part in undergraduate teaching and to pursue research in his field of interest.

Salary scale £2,118-£4,896 (1st October, 1974) with placing according to qualifications and experience. F.S.S.U. benefits.

Application forms and further particulars (quoting 23/74) may be obtained from the Registrar, University of Strathclyde, Royal College Building, 204 George Street, Glasgow, G1 1XW with whom applications should be lodged by 17 June, 1974. (2316)

UNIVERSITY OF GLASGOW
DENTAL HOSPITAL AND SCHOOL
RESEARCH ASSISTANTSHIP IN BIOCHEMISTRY

Applications are invited for a RESEARCH ASSISTANTSHIP in BIOCHEMISTRY, tenable for a period of three years from September or October 1974.

Candidates should have an Honours Degree in Biochemistry or an allied subject. There will be an opportunity to apply to register for a higher degree.

The work will involve a study of salivary proteins with a view to correlating abnormalities with pathological disorders. The project is financed by a grant from the Scottish Home and Health Department.

Salary Scale £1,500 to £1,650 per annum. F.S.S.U.

Applications, including curriculum vitae and names of two referees, should be sent to Dr. J. A. Beeley, Department of Dental Biochemistry, University of Glasgow Dental School, 378 Sauchiehall Street, Glasgow, G2 3JZ, from whom further information may be obtained. (2298)

UNIVERSITY OF IBADAN
NIGERIA

Applications are invited for the post of READER IN PHYSICAL BIOCHEMISTRY OR MICROBIOLOGICAL CHEMISTRY in the Department of Biochemistry. Applicants should hold a research doctorate and have several years academic experience. Salary: N6,100 p.a. (£1 sterling=N1.47). The British Expatriates Supplementation Scheme is unlikely to be applied to this appointment. F.S.S.U. Family passages; various allowances; regular overseas leave. Detailed applications (2 copies) including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than 1st July 1974 to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars of these appointments may be obtained from either address. (2307)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF PHYSICS

Eighteen months postdoctoral appointment for research on photophysics of aromatic hydrocarbons at Synchrotron Radiation Facility, Daresbury. Apply Dr S. Hamilton, Manchester M13 9PL (Phone 061-273 3333) as soon as possible. (2329)

UNIVERSITY OF CAPE TOWN
SOUTH AFRICA
SENIOR LECTURER IN DEPARTMENT OF MICROBIOLOGY

Applications invited for above post at University of Cape Town. Salary commensurate with Senior Lectureship status and local conditions. Starting salary dependent on qualifications, which should include experience in Virology or Immunology.

Full details on request.

Submit resumé and names and addresses of references to:

Registrar, University of Cape Town, Private Bag, Rondebosch, Cape Town, South Africa.

Closing date July 31, 1974. (2317)

THE UNIVERSITY OF SHEFFIELD
UNIVERSITY DEPARTMENT OF MEDICINE, THE ROYAL HOSPITAL
RESEARCH ASSISTANT

required for investigation concerning regulation of gastrointestinal fluid transport in experimental animal and man, financed by The Wellcome Trust. Applicants should be science graduates with some postgraduate laboratory experience. The post is tenable for up to three years from a date to be arranged. The work would be suitable for a higher science degree. Initial salary £1,929 a year, rising to £2,223 a year, subject to limitation if the person appointed registers for a higher degree. Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications should be sent by June 21, 1974. Please quote reference R85/G. (2328)

BEDFORD COLLEGE
(UNIVERSITY OF LONDON)
RESEARCH ASSISTANT
in
ZOOLOGY

Research Assistant required to work under a three year N.R.C. grant on the neurophysiology and behaviour associated with limb shedding in crabs.

Applications are invited from recently qualified, or soon to be qualified graduates, who have had experience in neurophysiology and routine microscopy. The work will involve visits to a marine laboratory. The appointment will date from October 1, 1974. Salary scale £1,500 by 2/87 to £1,674 p.a.

Applications quoting names of two referees, to: Assistant Secretary (Personnel), Bedford College, Regent's Park, London NW1 4NS. (Tel. 01-486 4400, Ext. 312). (2327)

THE ANIMAL HEALTH TRUST
EQUINE RESEARCH STATION, NEWMARKET
CHEMIST/BIOCHEMIST

Applications are invited for the post of research assistant in the laboratory for chemical pathology to undertake research into the basic chemical pathology of the thoroughbred racehorse.

The post is for three years in the first instance and is suitable for a graduate in biological sciences wishing to work for a higher degree. Salary on scale £1,560 to £1,704 per annum with F.S.S.U. benefits.

Further details and application forms are available from the Chief Executive Officer, The Animal Health Trust, 24 Portland Place, London W1N 4HN. (2330)

ROYAL STATISTICAL SOCIETY
LIBRARIAN

The Royal Statistical Society invites applications for the post of Librarian. Candidates should be Chartered Librarians, will be expected to have had considerable experience of library work, preferably in the statistical or analogous fields and will be required to take over the duties of the present Librarian within a year.

The Library is situated near Manchester Square and other staff are employed.

Starting salary in accordance with age and experience within a competitive salary scale.

Applications in writing to the Secretary, Royal Statistical Society, 21 Bentinck Street, London W1M 6AR. (2331)

MEDICAL RESEARCH COUNCIL

An adequately qualified technician required to work in the Virology Laboratory of the

Laboratory Animals Centre
Woodmansterne Road
Carshalton, Surrey

The position calls for an experienced person with the ability to adapt and/or devise techniques for incorporation into a comprehensive routine for the diagnosis of disease in a wide range of laboratory animals, mainly using serological procedures.

The ability to work on his own initiative and with a minimum of supervision calls for a high level of self-starting and self-maintaining potential.

For the right person, this could be a most rewarding position in a little known but expanding field.

Salary scale ranging from £1,440 to £2,292 plus London Weighting.

Application forms available from the Chief Technician's Office or telephone 01-643 8000.

(2333)

LIVERPOOL POLYTECHNIC
DEPARTMENT OF BIOLOGY
LECTURER GRADE II IN PHYSIOLOGY

Applications are invited for the post of Lecturer Grade II in Animal Physiology. Applicants should have an interest in the Environmental Aspects of Animal Physiology, have a good Honours Degree and have pursued a research problem to the level of Ph.D. Teaching or Industrial/Research station experience would be of advantage. The successful candidate will be expected to teach to Honours Degree level, to contribute to the post-graduate teaching programme and to undertake research.

SALARY: £2,700 to £3,474 p.a.

Details available from Staff Office, Dept. N, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool, L3 9RH. (2321)

THE QUEEN'S UNIVERSITY OF BELFAST
SENIOR EXPERIMENTAL OFFICER IN ELECTRON MICROSCOPY

Applications are invited for the post of Senior Research Officer in Electron Microscopy in the Department of Pathology. Candidates should have a University Degree or equivalent qualification in a relevant scientific subject. Extensive experience is required in the conduct and management of an Electron Microscope Laboratory including all aspects of maintenance and service. Research experience in the structure of biological materials would be an advantage and the appointee will be expected to conduct research on the nature of connective tissue and to collaborate in other University research programmes. The appointee will take part in the provision of diagnostic services to the Royal Victoria and City Hospitals under the direction of Professor Gardner. The post will carry a limited undergraduate teaching commitment. The salary scale is £2,736 to £3,708 (under review) plus F.S.S.U. Initial placing on the scale will depend on qualifications and experience. Application should be made in writing, giving details of qualifications and experience and the names of two referees, to the Personnel Officer, The Queen's University of Belfast, Belfast BT7 1NN, Northern Ireland, by June 30, 1974. (2325)

NATIONAL INSTITUTE OF AGRICULTURAL ENGINEERING
SCOTTISH STATION
ABSTRACTOR/LIBRARIAN

Abstractor/Librarian required by Agricultural Research Institute to run small library, provide scientific information and abstracting service to staff, arrange translation of scientific papers, etc.

The appointment will be on Higher Scientific Officer Grade, salary for which is £2,221 to £2,854 by eight annual increments.

Further details and application form from the Secretary, N.I.A.E., Scottish Station, Bush Estate, Penicuik, Midlothian, EH26 0PH, to whom completed forms should be returned by June 21, 1974. (2320)

OXFORD UNIVERSITY
DEPARTMENT OF ZOOLOGY

Applications are invited for the post of Research Assistant to work under Dr Malcolm Coe on the reproductive biology of Giant Tortoises on Aldabra Island in the Indian Ocean. The appointment will be for a period not exceeding three years, of which two years will be spent carrying out field work on Aldabra and one year in Oxford.

Applicants should be available to take up this post by the beginning of August 1974. Preference will be given to candidates with an interest or experience in the field of Herpetology. Salary will be by arrangement according to age, qualifications and experience.

Applications with a full curriculum vitae and the names of two referees should be sent immediately to the Secretary, Animal Ecology Research Group, Department of Zoology, South Parks Road, Oxford OX1 3PS. (2334)

F.R.A.M.E.

which is concerned with disseminating information on alternatives to laboratory animals seeks science graduate with initiative to assist with P.R. work, literature searching and abstracting. The post is challenging and offers great scope to anyone seeking a rewarding job with a real sense of purpose. For further details write to: The Secretary, F.R.A.M.E. (Fund for the Replacement of Animals in Medical Experiments), 312a Worple Road, London SW20 8QU. (2332)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF ANATOMY
BEHAVIOUR OF NON HUMAN PRIMATES

RESEARCH STUDENTSHIP available for studying the effects of hormones on the behaviour of non-human primates. Acceptance subject to the University's regulations for research students. Applications (with the names of two referees) to Dr J. Herbert, Department of Anatomy, Downing Street, Cambridge CB2 3DY. (2127)

RESEARCH STUDENTSHIP

Applications are invited for a three-year research studentship to study aspects of the vitamin requirements of the Golden hamster (**Mesocricetus auratus**). Applicants should have or expect to attain this summer, first or upper second class honours degree in nutrition, or a relevant biological discipline. The successful candidate who will register for further degree, will receive a grant plus a small travel and book allowance, and fees will also be paid.

Applications with names of two referees and short curriculum vitae should be made to Dr. D. J. Ford, Medical Research Council, Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF, from whom further details may be obtained. (2019)

THE SCHOOL OF PHARMACY
UNIVERSITY OF LONDON
DEPARTMENT OF PHARMACOLOGY
BRAIN RESEARCH STUDENTSHIP

Applications are invited from students graduating in biochemistry, physiology or pharmacology for an M.R.C. Research Studentship. The successful applicant will work with Dr M. J. Neal on various aspects of transmitter substances in the brain.

Applications, with the names of two referees should be sent to Dr M. J. Neal, Department of Pharmacology, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX. (2217)

UNIVERSITY OF QUEENSLAND
AUSTRALIA
POSTDOCTORAL FELLOWSHIP

Solid state physicist with experimental or theoretical experience in semi-conductors to join solar energy project on photovoltaic cells using organic materials.

Salary in range $A8,698 to $A14,308 per annum, plus 10% superannuation.

Start early 1975. Appointment 1 year, renewable, maximum 3 years.

Write to Professor L. E. Lyons, Department of Chemistry, University of Queensland, St. Lucia, Brisbane, Queensland 4067, Australia. (2219)

The POLYTECHNIC WOLVERHAMPTON

Faculty of Science:

Research Studentships

Applications are invited for studentships tenable from September 1974 on the following research projects:

SRC Case Studentships
(with Shell Research)
Insect acetylcholine receptor molecules.
Plant cell plasma membranes.

(with Koch-Light Ltd)
Non-aqueous applications of water-insoluble enzymes.
Biospecific absorbents.
High speed gel permeation chromatography.

Industrial Studentships
Affinity chromatography.
Solid phase synthesis.

Applicants should normally hold by September appropriate honours degrees or equivalent professional qualifications. Applications (curriculum vitae and names of 2 referees) or requests for further information to the Establishment Officer, The Polytechnic, Wolverhampton WV1 1LY.

(2212)

THE QUEEN'S UNIVERSITY OF BELFAST
DEPARTMENT OF INDUSTRIAL CHEMISTRY

Post Graduate Studentships

Applications are invited for the above studentships which are tenable for three years. The topics of research include: Studies in the crosslinking reactions of proteins related to nutrition; Oxidation reactions in the bleaching of cellulosic fibres; Studies in the depolymerisation of polypropylene in the recycling of waste materials; Chemical engineering studies related to the drying of fabrics; Physico-chemical studies of the dyeing mechanisms of protein fibres.

Post graduate studentships are normally valued at about £700 p.a. plus fees.

Applicants should have an honours degree in chemistry, biochemistry or chemical engineering (or equivalent professional qualifications). Applications should be received by August 1, 1974. Further details from Professor R. S. Asquith, Department of Industrial Chemistry, The Queen's University of Belfast, Belfast 9.

(2324)

UNIVERSITY OF SALFORD
Department of Pure and Applied Physics

Research Studentships

Applications are invited from candidates holding or expecting to obtain shortly an honours degree or equivalent qualification in an appropriate discipline, for research studentships leading to higher degrees. The current value of the awards, normally tenable for 3 years, is £695 p.a. plus approved fees. Research studentships are available for:

1. An investigation of thermal characteristics of transition metal oxide switching glasses, in collaboration with Standard Telecommunication Laboratories Ltd., Harlow. This is an S.R.C. (C.A.S.E.) award.
2. Investigations of thermoelastic properties of carbon fibre reinforced composites, in collaboration with the Royal Aircraft Establishment, Farnborough.

Further details of these and other research awards may be obtained from the Registrar, Room 102, University of Salford, Salford M5 4WT, quoting reference Nat/86. Informal enquiries may be made to Professor R. R. Birss, Chairman of the Department of Pure and Applied Physics, University of Salford, Salford M5 4WT. (2239)

UNIVERSITY OF GLASGOW
Department of Natural Philisophy
RESEARCH FELLOWSHIP
Solid State Physics Group

A postdoctoral research fellow is required to join a group concerned with structural studies of the surface of liquids by high energy reflection electron diffraction. At a later date this work may be extended to investigations of solid state surface phenomena. Experience of U.H.V. and/or electron diffraction methods would be desirable but not essential.

Salary scale for the post will normally be within the range £1,929 to £2,223 per annum according to age and experience. Tenure two years on appointment with possible renewal for a further year. F.S.S.U. benefits.

Applications stating age, academic qualifications, research experience and the names of two referees should be submitted not later than June 28, 1974, to Professor R. P. Ferrier, Department of Natural Philosophy, University of Glasgow G12 8QQ. In reply please quote Ref. No. 3438M.

(2231)

UNIVERSITY OF LIVERPOOL
RESEARCH STUDENTSHIP IN BIOCHEMISTRY

Applications are invited for an S.R.C. Research Studentship to study some aspects of Affinity Chromatography. Applicants should hold or expect to receive a good honours degree in Biochemistry and will be encouraged to submit for a higher degree.

Applications, stating age, qualifications and experience, together with the names of two academic referees, should be sent to the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/N/276050. (2265)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY
RESEARCH STUDENTSHIPS

Applications are invited from graduates, or from those who expect to graduate this summer, for Research Studentships to undertake research work for higher degrees. The Department has a wide research interest in several areas of physiology and biochemistry.

Further details and application forms obtainable from Postgraduate Admissions Office, Department of Physiology and Biochemistry, Medical and Biological Sciences Building, The University of Southampton, Bassett Crescent East, Southampton SO9 3TU. (2211)

UNIVERSITY OF DUBLIN
Trinity College

Post-Doctoral Fellowship in the Department of Genetics

As part of the Commission of the European Communities Environmental Research Programme a team is being assembled to develop a European Mutagenicity and Carcinogenicity Test System using mice and micro-organisms.

A post-doctoral fellow is required to develop suitable strains of mice and to use these for testing the mutagenicity of actual and potential carcinogens: a knowledge of mouse genetics is desirable.

The starting salary will not be less than £2,000 per annum and applications, naming 2 referees, should be sent to:

Professor G. W. P. Dawson,
Department of Genetics,
Trinity College,
DUBLIN 2.

(2319)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

Applications are invited from graduates with a 1st or upper 2nd class Honours degree in Biochemistry or other relevant subject, or from those graduating this year, for an S.R.C. Research Studentship tenable from October 1, 1974, leading to a higher degree in the University of London. The person appointed will be able to study the biochemistry of vitamin E, selenium, and membrane systems with Dr A. T. Diplock. Applicants should send a Curriculum vitae and the names of two referees, as soon as possible, to Professor J. A. Lucy, Royal Free Hospital School of Medicine, 8 Hunter Street, London WC1N 1BP. (2223)

UNIVERSITY OF GLASGOW
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL FELLOWSHIP

Applications are invited for a POST-DOCTORAL FELLOWSHIP to investigate the mechanism and stereochemistry of ENZYMIC REACTIONS by chemical and computational studies of model systems. Applicants should have experience of organic synthesis but previous experience of computing is not essential. The Fellowship is sponsored by the Enzyme Chemistry and Technology Committee of the Science Research Council. Appointment will be for two years from October 1, 1974, on the salary scale £2,118 to £2,247 to £2,412 per annum.

Applications, including the names of two referees, should be sent as soon as possible to Professor K. H. Overton, Department of Chemistry, The University of Glasgow, Glasgow, G12 8QQ, Scotland.

In reply please quote Ref. No. 3471M. (2229)

POLYTECHNIC OF THE SOUTH BANK
FACULTY OF ENVIRONMENTAL SCIENCE AND TECHNOLOGY
S.R.C. RESEARCH STUDENTSHIPS

Applications are invited for research studentships in Environmental Science and Technology.

Projects, suitable for Higher Degrees, are available in the following areas:

I. Thermal Comfort.
II. Control of Noise.
III. Ventilation of Buildings.
IV. Two phase flow (Liquid/gas; Solid/gas).
V. Heat Pumps.

Candidates should either have (or expect to acquire in 1974) a good honours degree in Science or Engineering.

Further particulars from Dr D. R. Scott, Head of Faculty of Environmental Science and Technology, Polytechnic of the South Bank, Borough Road, London SE1 0AA. Tel. 01-928 8989. (2318)

UNIVERSITY OF BIRMINGHAM

Department of Pharmacology (Preclinical) and MRC Neuropharmacology Unit

POSTGRADUATE RESEARCH STUDENTSHIPS

Applications are invited for 2 research studentships supported by the Medical Research Council, commencing on 1 October 1974. The research work of the Department and Unit covers various aspects of the pharmacology of the central nervous system with special reference to the mode of action of drugs, and there are opportunities for learning new techniques such as microiontophoresis, radiochemical assay and zonal centrifugation.

Applicants should have a 1st or upper 2nd Class Honours degree in pharmacology, biochemistry, physiology or related biological subjects.

Applications, in writing to:

Professor P. B. Bradley,
Dept. of Pharmacology (Preclinical),
Medical School,
Birmingham,
B15 2TJ (2273)

UNIVERSITY COLLEGE CARDIFF
DEPARTMENT OF BIOCHEMISTRY
RESEARCH STUDENTSHIPS AND TUTORIAL FELLOWSHIP

Two C.A.S.E. postgraduate studentships are available from October 1 for the following projects: (a) Biosynthesis and function of hexadecanoic acid in higher plant chloroplasts—supervised jointly by Dr J. L. Harwood (Cardiff) and Dr A. T. James (Unilever Ltd.); (b) Techniques for the study of organ specificity as applied to the metabolism of drugs—supervised jointly by Drs A. H. Olavesen and C. G. Curtis (Cardiff) and Dr R. F. Collins (May and Baker Ltd.). Ref. 0580.

Tutorial Fellowship available as from October 1. The successful applicant will be expected to participate in some of the teaching activities of the department and to undertake research on either enzymology or on dopamine metabolism. The appointment will be for three years and it will be possible to register for a higher degree. Salary for this appointment on the scale £1,311 to £1,392 to £1,473 (under review). Ref. 0580A.

For all the above appointments an Upper Second Class Honours Degree or better will be required.

Applications as soon as possible (and not later than June 30) to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Further information can be obtained from Professor K. S. Dodgson, Department of Biochemistry. (2289)

UNIVERSITY OF DURHAM RESEARCH STUDENTSHIPS IN CHEMISTRY

Funds are available to finance research studentships in chemistry in the following areas:

(i) Studies of some cyclic sulphonyl imides. An investigation of the reactivity of some sulphur-nitrogen ring systems and their conversion to compounds with potential application in bio-degradable agricultural products and polymers.
(ii) Synthetic and mechanistic studies in the field of organic-fluorine chemistry.
(iii) Electrochemical techniques for organic synthesis.
(iv) Inelastic neutron scattering in molecular spectroscopy. An investigation of some librational and vibrational transitions of molecular systems, which are not infrared and Raman active, by inelastic neutron scattering spectroscopy.

Project (i) is supported by a C.A.S.E. studentship. The equivalent of an upper second class honours degree or better will be required for all projects. For project (iv) a degree in physics or a joint honours degree in physics/chemistry or maths/chemistry is as acceptable as one in chemistry.

Applications, with class of degree, or approximate date of degree results, together with the names of two referees should be sent as soon as possible to Professor T. C. Waddington, Department of Chemistry, Science Laboratories, South Road, Durham DH1 3LE. (2208)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(UNIVERSITY OF LONDON)

Applications are invited from graduates in Pharmacology or Physiology for a Research Fellowship (value £1,344 p.a.) in the Department of Pharmacology. Good research facilities are available in a variety of fields and experience in electron microscopy would be an advantage. The successful candidate will be eligible to register for a higher degree. Applications should be sent to the School Secretary, 8 Hunter Street, London WC1N 1BP. (2224)

IMPERIAL COLLEGE DEPARTMENT OF CHEMISTRY

Applications invited for two S.R.C. C.A.S.E. research studentships leading to Ph.D. and concerned with analytical chemistry in:

1. Low-temperature luminescence spectrometry for determination of carcinogenic aromatic hydrocarbons in biological materials (in association with Huntingdon Research Centre).
2. Single- and multi-channel quasi-linear luminescence spectrometry for organic trace analysis (in association with Applied Research Laboratories Limited).

Normal conditions for S.R.C. studentships apply. Further information from and applications to Dr G. F. Kirkbright, Department of Chemistry, Imperial College, London SW7 2AY. (2287)

UNIVERSITY OF EDINBURGH RESEARCH STUDENTSHIPS IN PHYSIOLOGY

Applications are invited from recent graduates in Veterinary Medicine, Medicine or holding a good honours degree in Science, and from final-year students expecting to graduate this year, for M.R.C. and S.R.C. Studentships for Training in Research Methods, tenable at the Department of Veterinary Physiology in the University of Edinburgh. The major areas of research are the neurosciences, especially sensory neurophysiology. An M.Sc. course is run in neurophysiology.

Applications to Professor A. Iggo, Department of Veterinary Physiology, University of Edinburgh, Edinburgh, EH9 1QH (2313)

UNIVERSITY OF GLASGOW
RESEARCH FELLOWSHIP IN EXPERIMENTAL PHYSICS

Applications are invited for a research fellowship in experimental high energy physics. The post is concerned with either the programme of work using the OMEGA spectrometer at CERN or meson photoproduction at Daresbury, and with planning of experiments on the CERN SPS.

Salary will be within the range £2,118 to £2,412 per annum of the new Lecturer's salary scale which will be effective from October 1, 1974, and the post will qualify for F.S.S.U. Applications should be submitted as soon as possible giving full details of qualifications and experience and should be sent to Professor J. C. Gunn, Department of Natural Philosophy, The University of Glasgow, Glasgow, C12 8QQ.

In reply please quote Ref. No. 3470M. (2230)

UNIVERSITY OF ABERDEEN RESEARCH STUDENTSHIP IN MICROBIOLOGY

Applications are invited from Microbiologists, Biochemists or Biologists with an interest in pollution to investigate the ecology of micro-organisms within the estuary of the River Don.

This research, which is sponsored by grants to Dr. N. J. Poole from local Government and Industrial Organisations, will be suitable for submission for the degree of Ph.D. The value of the award will be similar to that of Research Council Studentships.

Further particulars from the Unit of Microbiology, Department of Biochemistry, University of Aberdeen, Marischal College, Aberdeen, AB1 9AS.

Applications (2 copies) should be lodged by June 29, 1974. (2315)

THE OPEN UNIVERSITY RESEARCH STUDENTSHIP IN CHEMISTRY

Applications are invited from candidates with, or expecting to obtain in June 1974 a good honours degree for a Research Studentship in Chemistry.

Molecular evolution

Theoretical interpretation of 'other nucleus' NMR shift

Mechanisms of thermal elimination

Unusual oxidation states of the transition metals.

The value of the award will be £695 with appropriate additional allowances. Further particulars and application forms may be obtained from: **The Higher Degrees Office, P.O. Box 49, Milton Keynes, MK7 6AD.**

Please quote ref: CHEM/2.

Closing date for receipt of applications: June 18. (2271)

UNIVERSITY OF WARWICK
POSTDOCTORAL FELLOWSHIP
IN BIOCHEMISTRY

Applications are invited for a Postdoctoral Fellowship in Biochemistry, in the Department of Molecular Sciences, to work on the enzymology of the A.T.P. ase (A.T.P. synthase) complex from yeast and E.Coli. Experience in enzyme isolation and/or protein chemistry would be an advantage. The appointment is for two years commencing 1st October 1974. Salary in the range £2,118, £2,247, £2,412 p.a. with F.S.S.U. Further details may be obtained from the Academic Registrar, University of Warwick, Coventry, CV4 7AL, to whom completed applications should be returned by July 31, 1974. Please quote Ref. No. 44/Q/74. (2299)

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MEDICAL PHYSICS
DEPARTMENTAL
RESEARCH STUDENTSHIP

Applications are invited for above Studentship in the Department of Medical Physics (Head, Professor J. R. Mallard) from graduates in Chemistry or Physics.

The research topic is study of light emitted during dissolution of irradiated solids and the applications of this effect. The studentship is supported by the National Radiological Protection Board and its value is £695 per annum.

Applications (2 copies) giving details of qualifications and names of referees should be sent to the Secretary, University of Aberdeen, by June 30, 1974. (2323)

SITUATION REQUIRED

PALAEONTOLOGIST

(Female, 28, Ph.D. Glasgow 1971) presently bored to tears in academic library, seeks post with more intellectual challenge. Salary above bread-line. Write Box No. 2270, Nature, T. G. Scott & Son, 1 Clement's Inn, London WC2A 2ED. (2270)

FOR SALE AND WANTED

Always wanted:
BACK RUNS OF JOURNALS

MISCELLANEOUS

TO LET

Available to careful visiting family for one year from July, small house South Hampstead (inner N.W. London). Quiet, 4 bedrooms, gas central heating. £100 per month. Write Box No. 2301, Nature, T. G. Scott & Son Ltd., 1 Clement's Inn, London WC2A 2ED, or telephone 01-267 2489. (2301)

LECTURES AND COURSES

UNIVERSITY OF EDINBURGH
DEPARTMENT OF
VETERINARY PHYSIOLOGY
M.Sc. IN NEUROPHYSIOLOGY

Applications are invited for admission to the above course, which is an advanced interdisciplinary course in neurophysiology leading to an M.Sc. and is open to full-time students.

Applications for admission are invited from graduates in veterinary medicine or medicine and from graduates with at least Second Class Honours in Science.

Further information from and applications to Professor A. Iggo, Department of Veterinary Physiology, University of Edinburgh, EH9 1QH. (2314)

KINGSTON
POLYTECHNIC

MSc in Analytical Chemistry

starting September 1974

A two-year part-time course providing a broadly-based, up-to-date treatment of the subject with opportunities for specialisation through project work.

Further particulars from the Secretary, School of Chemical and Physical Sciences, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. (2235)

HARWELL SUMMER SCHOOL
ON
THERMAL NEUTRON SCATTERING
to be held at the
Harwell Education Centre, Oxfordshire, U.K.
15 to 20 September 1974

The primary purpose of the School is to give students the opportunity of performing neutron scattering experiments at the Harwell PLUTO and DIDO reactors. There will be lectures covering the basic background theory. Each student will attempt at least two experiments using apparatus which will include a four-circle neutron diffractometer, polarised neutron diffractometer, cold neutron time of flight spectrometer, double chopper spectrometer, and hot neutron LINAC spectrometer.

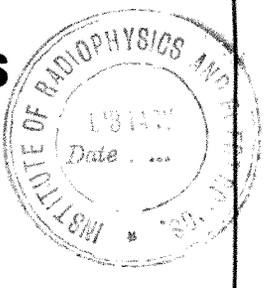
The experiments will cover the determination of crystal and magnetic structures, the measurement of diffusion of liquids, and the study of phonon dispersion relations and phonon density of states.

APPLICATIONS are invited from postgraduate research workers and final year undergraduates.

Application forms and further details are available from:

Dr. B. T. M. Willis
Atomic Energy Research Establishment
Harwell
Didcot
Oxfordshire

HARWELL
Education Centre



Closing date for applications: 22 July 1974.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:
Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes,** M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage,** D. P. Tihansky. **Effects of Red Mud on Marine Animals,** R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn,** M. Karpuzcu.

Annual Subscription £6.50 (£7.50 USA and Canada). Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

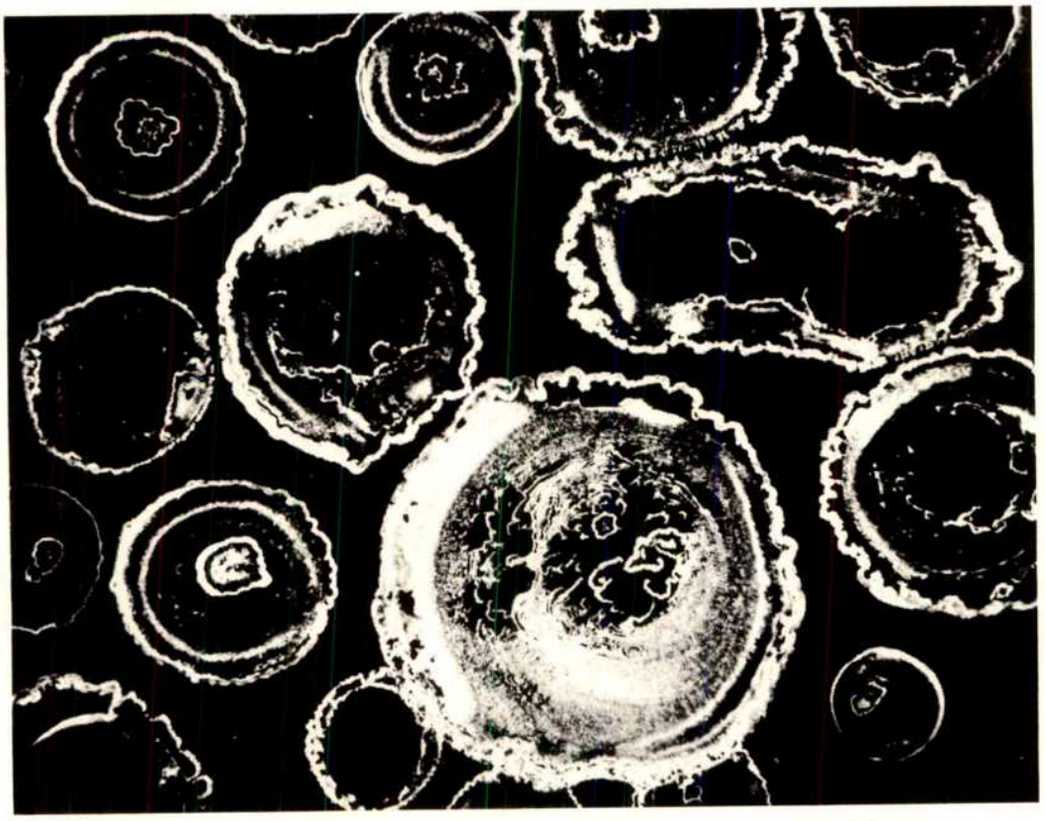
new

A choice of bright or dark field in the stereomicroscope



Wild M7 Zoom Stereomicroscope with transmitted-light stand (bright and dark field)

The new transmitted-light stand for Wild stereomicroscopes is designed for both bright and dark field. No adjustment is necessary - just move a lever and you change straight from one to the other. The fan-cooled 12 V/100 W halogen lamp gives uniform illumination, so the new stand is particularly suitable for photomicrography.

Ask for brochure M1 117.

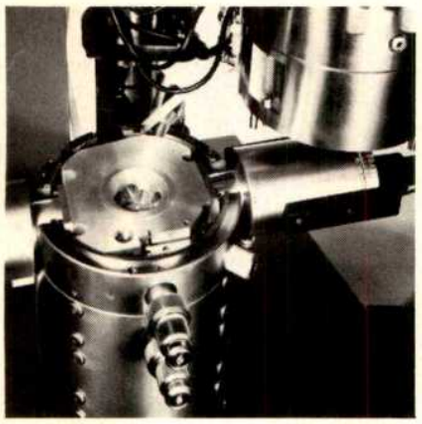
YOUR FUTURE IN ELECTRON OPTICS...

WILL YOU WANT A SYSTEM THAT CAN GROW ALONG WITH YOUR NEEDS AND YOUR BUDGET?

As electron microscopes approach the theoretical limits to resolution, their useful lifetime is extending dramatically.



The problem... if you want to call it that... is that other aspects of electron optics are still being improved. New ways of getting more information from a point in a specimen are continuously being developed. How can you benefit from this growing technology... without buying more than you need, or replacing your instrument every few years?

Philips' answer is the **systems approach** to electron optics. **No matter what your future holds... there's a Philips microscope for you now!**

For example. Start with the advanced research **EM 301** (or your **EM 300**). Add a goniometer for tilting capability. Add a S(T)EM unit later, and you'll have, at your fingertips, instant choise of TEM, STEM or SEM. Add an energy dispersive x-ray analyser for micro-chemical analysis. Choose from a full range of cameras, TV displays, image intensifiers and video recorders. **Add on when your ready... without ever compromising the excellent versatility of the basic instrument.**

Highest performence... plus inherent versatility extending far into the future. It's yours with Philips. **Order a Data File and see.**

Cell Let the contents speak for themselves.

The June issue of Cell will include the following articles, reviews, and book reviews:

The Gene Numbers Game: J. O. Bishop

Evidence for Genetic Recombination Between Endogenous and Exogenous Mouse RNA Type C Viruses; J. R. Stephenson, G. R. Anderson, S. R. Tronick, and S. A. Aaronson

Increased Protease Levels in Transformed Cells: A Casein Overlay Assay for the Detection of Plasminogen Activator Production: A. R. Goldberg

Changes in Adenylate Cyclase, Cyclic AMP, and Protein Kinase Levels in Chick Myoblasts, and Ther Relationship to Differentiation: R. J. Zalin and W. Montague

Induction of a Deoxycytidineless State in Cultured Mammalian Cells by Bromodeoxyuridine: M. Meuth and H. Green

Expression of Thymidine Kinase Variants is a Function of the Replicative State of Cells: R. Adler and B. R. McAuslan

Book Reviews

Among the Protozoologists: S. H. Hutner
Cell Culture—the State of the Art: J. Bard
Ribonucleic Acids in Review: E. M. Scolnick

The July issue of Cell will include the following reviews and articles:

A Unified Theory of the Control of Actin and Myosin in Nonmuscle Movements: A. C. H. Durham

The Role of Protein Factors in the Biosynthesis of Proteins: H. Weissbach and N. Brot

An Electron Microscope Study of the Effects of Cyclic AMP on Chinese Hamster Ovary Cells: K. R. Porter, T. T. Puck, A. W. Hsie, and D. Kelley

The Morphology and Growth of a Pluripotent Teratocarcinoma Cell Line and its Derivatives in Tissue Culture: G. R. Martin and M. J. Evans

Isolation and Biochemical Characterization of Folate Deficient Mutants of Chinese Hamster Cells: M. W. McBurney and G. F. Whitmore

Characterization of a Chinese Hamster Cell with a Temperature-Sensitive Mutation in Folate Metabolism: M. W. McBurney and G. F. Whitmore

The Degradation of Ribonucleic Acids Injected into Xenopus Laevis Oocytes: C. C. Allende, J. E. Allende, and R. A. Firtel

Poly Adenylic Acid Synthesis In Vitro in Isolated HeLa Cell Nuclei and Whole Cell Homogenates: W. R. Jelinek

The August issue of Cell includes the following articles:

Cytosol Androgen Receptors from Kidney of Normal and Testicular Feminized (Tfm) Mice: B. Attardi and S. Ohno

Isolation of Lymphoma Cell Variants Resistant to Killing by Glucocorticoids: C. H. Sibley and G. M. Tomkins

Mechanisms of Steroid Resistance: C. H. Sibley and G. M. Tomkins

Effect of Cyclic Nucleotides on the Induction of Ornithine Decarboxylase in BHK Cells by Serum and Insulin: B. Hogan, R. Shields, and D. Curtis

A Direct Stimulating Effect of Cyclic GMP on Purified Phosphoribosyl Pyrophosphate Synthetase and its Antagonism by Cyclic AMP: C. D. Green and D. W. Martin

Electrophoretic Characterization of Shuttling and Nonshuttling Small Nuclear RNAs: L. Goldstein and C. ko

Host Restriction of Friend Leukemia Virus: M. N. Sveda, B. N. Fields, and R. Soeiro

Poly (A) in mRNA Does Not Contribute to Secondary Structure Necessary for Protein Synthesis: R. F. Muñoz and J. E. Darnell

Identification of a Small Subfraction of hnRNA with the Characteristics of a Precursor to mRNA: R. P. Price and S. Penman

Subscription Prices
A year's subscription to Cell is $70 for individuals in the U.S., Canada, or Pan American Postal Union and $75 for individuals in other countries. The subscription price for institutions is $100 in the U.S., Canada, or Pan American Postal Union and $105 for institutions in other countries.

Sample copies sent upon request.

Manuscripts and editorial correspondence should be addressed to the Editor or European Editor.

Guide to authors

Nature accepts three types of communications:

● Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

● 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Involvement of brain cholinergic mechanisms in the action of chlorpromazine—*M. Trabucchi, D. Cheney, G. Racagni and E. Costa* 664

Effect of histamine H-receptor blockade on fasting serum gastrin and fasting gastric acid secretion in the dog—*G. O. Barbezat, M. Daniel, S. Bank, B. Grant and A. Vinik* 666

Cone mechanisms initiating response of on-off goldfish optic fibres—*R. D. Beauchamp* 668

Genetic variation in marine fishes as a test of the niche-variation hypothesis—*G. N. Somero and M. Soule* 670

Nitrosation of phenols in smoked bacon—*M. E. Knowles, J. Gilbert and D. J. McWeeny* 672

Inhibition of inter-microbial predation by chlorinated hydrocarbons—*F. Walsh and R. Mitchell* 673

Formation of methylmercury in a terrestrial environment—*W. F. Beckert, A. A. Moghissi, F. H. F. Au, E. W. Bretthauer and J. C. McFarlane* 674

New finding of the ancient primitive mollusc *Neopilina* in the Atlantic part of the Antarctic—*Z. A. Filatova, N. G. Vinogradova and L. I. Moskalev* 675

Effects of stable chlorine-containing organics on aquatic environments—*C. W. Gehrs, L. D. Eyman, R. J. Jolley and J. E. Thompson* 675

BOOK REVIEWS

Physics at 17th and 18th Century Leiden: Philosophy and the New Science in the University (E. G. Ruestow)—*C. B. Schmitt* 677

Trypanosomiasis and Leishmaniasis with Special Reference to Chagas' Disease (Ciba Symposium)—*F. E. G. Cox* 677

The Development of the Chlorinity/Salinity Concept in Oceanography (W. J. Wallace)—*G. E. R. Deacon* 678

Quantum Mechanics in a New Key (Alfred Landé)—*J. E. G. Farina* 678

A new d.c. Microvoltmeter

The TF 2655 is a high-grade, versatile, general-purpose instrument with 18 voltage and 14 current ranges, all with an accuracy of ±2% f.s.d.

Its main features are:

* push-button selection of ranges and polarity
* high-input resistance of 10^6 Ω to 10^{11} Ω
* low constant voltage drop of 10mV on all current ranges
* off-set zero
* large, 9.5cm, clear-reading, mirror scale
* input overload protection ±100V up to 1V range, and ±1,200V on remainder

Ranges: 3 μV to 1,000V f.s.d. in 3/10 sequence (18 ranges)
300pA to 1mA f.s.d. in 3/10 sequence (14 ranges)

Price: £150.
Made in Poland.

INSTITUTE OF ASTROPHYSICS AND GEOPHYSICS Date

In defence of the anonymous referee

SINCE Professor Fraenkel-Conrat's plea for an end to anonymity in the evaluation of scientific manuscripts three months ago we have received several more letters on the subject. One or two have been published, but the majority have said little more than 'me-too' in tones ranging from the reasonable to the outraged and lengths ranging from one paragraph to ten pages. The question of anonymity in refereeing appears regularly in the correspondence columns of scientific journals, usually associated pejoratively with a cloak, and it is desirable that scientists give more than a passing thought to it every few years. In most other fields the arbitrator is not anonymous—justice, sport, criticism of the arts, industrial relations all maintain highly visible decision-makers. Can science alone remain aloof from requiring personal accountability in its judgements?

Those who advocate the removal of the cloak point to two benefits which, it is claimed, would immediately accrue. Referees would have to take their job more seriously since their judgement would be semi-public, and the stab-in-the-back opportunity for the malevolent referee would disappear. There cannot be an editor who wouldn't be glad to eliminate careless or mischievous refereeing, although its incidence may well be greatly exaggerated. On the other hand the debit side of removing anonymity is rarely mentioned.

One of the commonest misconceptions about refereeing is that it is done by a small elevated community. A careful study by Zuckerman and Merton (*Minerva*, **9**, 66–100; 1971) showed very clearly that this was not true for *The Physical Review*, and although we have not the same impressive statistics to parade, the file of referees for *Nature* in 1973 contained more than a thousand names. Could we call on such numbers if the identities of referees were revealed? Only, we maintain, when the job was going to be the agreeable one of recommending the acceptance of excellent manuscripts. Large numbers of neither careless nor mischievous referees would send back, unreviewed, manuscripts which they believed to be inadequate and with those authors they had no desire to engage in combat.

Three points need emphasising.

First, referees should not be asked to endure face-to-face or even telephone encounters with irate authors. The sort of verbal roughing-up that even *Nature's* office staff occasionally have willed on them makes it clear that referees should not be placed in a position such that they can be got at by authors. The presentation of science is and must remain ultimately a written activity. This is not to deny the obvious power of the spoken word in education, exposition and elucidation. It is to deny the use of verbal battles, in which forcefulness, slick presentation and quick wittedness are prized assets in resolving scientific disputes. It would be unfair to ask a referee to engage in conflicts on our behalf, and in any case most would quite reasonably decline to do so. This would result in the decision-making process falling back on a smaller core of conflict-hardened reviewers.

Second, not all the unpleasant things that are said from behind the cloak of anonymity are said from a desire to do mischief. The rather common home truth 'this is the tenth paper based on the same data that the author has attempted to get into the literature in the last year' may be motivated less from malice than a genuine dislike of the practice of multiple publication. Such things would be less easy to say without anonymity—some forms of truthfulness would be positively impaired by identification.

Third, the anonymous opinion, to the conscientious author, cannot easily be discounted. The referee serves more than as just the expert vouching for technical plausibility. He is also the potential reader vouching for relevance, wide appeal and readability. He is the one sample of 'readership' opinion that an author will normally go on. The value of these functions can be diminished by knowing the referee's identity and therefore dismissing his critique on purely personal grounds.

Would identification even do what its advocates claim: bring more conscientious and honest reviewing and deter mischief-making? The latter, probably yes, to a certain extent, although most of those already involved in mutual back-stabbing are well enough known to each other not to worry much about anonymity. Some of these combatants are also well enough known to us not to be allowed too frequent a battle. The former, probably no. The tendency would be just as much towards pulling punches and being less critical.

The tradition of depersonalisation in the assessment of manuscripts has, we believe, served scientific communication well. There are obviously flaws in the system, but radical steps to remove these flaws might remove instead a lot which is good.

100 years ago

THE NEW PHYSICAL LABORATORY OF THE UNIVERSITY OF CAMBRIDGE

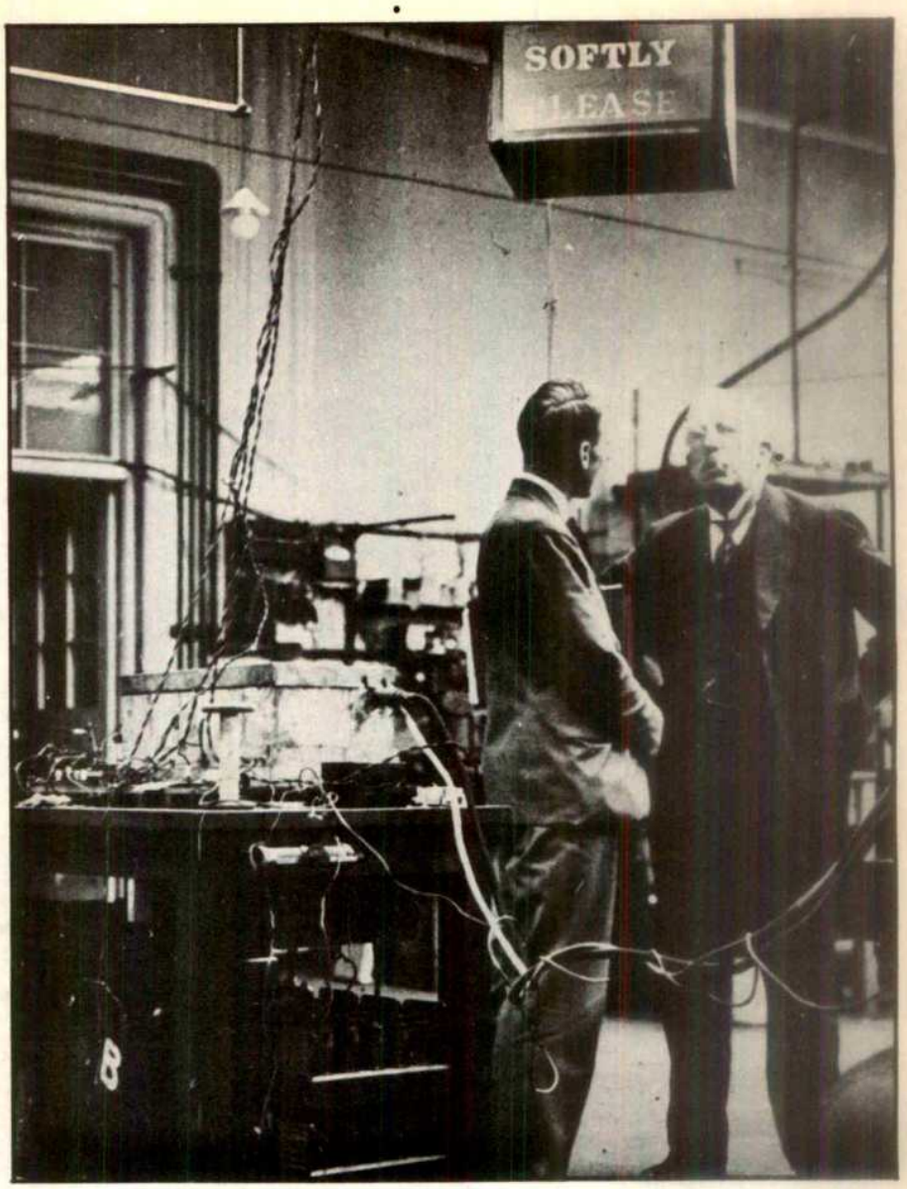
ON the 16th inst., at a congregation held in the Senate House, Cambridge, the Cavendish Laboratory was formally presented to the University by the Chancellor. The genius for research possessed by Prof. Clerk Maxwell and the fact that it is open to all students of the University of Cambridge for researches will, if we mistake not, make this before long a building very noteworthy in English science.

From *Nature*, **10**, 139, June 25, 1874.

The Cavendish tradition

Professor Brian Pippard, present Director of the Cavendish Laboratory looks at its rôle in the forefront of physical research during the century of its existence.

ON June 16, 1874, the doors of the Cavendish Laboratory were formally opened. A hundred years later, the last members of the Department of Physics left in those buildings are preparing to move to new quarters, still to be called the Cavendish Laboratory, on Madingley Road.



Cambridge was not the first university in the British Isles to encourage experimental physics, and if in its earliest years the Cavendish stood out from the rest, it was more because of its first two professors, Maxwell and Rayleigh, than for any notable difference in outlook. Only after this, with the inspired appointment of J. J. Thomson at the age of 27 (not without some grumbling about mere boys being made professors), did the work begin to develop a special character. Of course the change was not sudden, but it is clearly revealed by comparing the publications in Rayleigh's day (before 1885) with those of 15 years later. Rayleigh at Cambridge is a different man from the gentleman scientist of Terling; he maintains the academic tradition of what we may call Natural Philosophy, undertaking with his students careful measurements to illustrate and guide mathematical reasoning, and to provide values of the constants of nature that pure reason alone cannot determine. By 1898 one has to search hard to find any trace of the earlier attitude; all is qualitative, the laborious search for patterns in phenomena beyond the reach of mathematical prediction. The names are revealing — Thomson, Rutherford, C. T. R. Wilson, Townsend, Zeleny—the roll-call of early investigators of electrical conduction in gases. Thomson had started to work in this field as soon as he was appointed, had discovered the electron in 1897, and had built up a small team ready for action when the discovery of X rays and radioactivity swept away the old world of physics and inaugurated the golden age of string and sealing-wax.

Once more, let us remember that it was no sudden change; indeed, so far as the Cavendish was concerned these new effects principally gave new strength to the attack on gaseous conduction. But Rutherford in McGill was developing that technique which is now looked on as the epitome of the Cavendish tradition. How much was his own natural gift, and how much he picked up of what was congenial in J.J.'s approach, is hard to resolve; at all events, by the time he returned to the Cavendish in 1917, with his finest achievements behind him, he found there an outlook compatible with his own, and proceeded within the next few years to develop the laboratory to a world-commanding eminence.

This is the accepted version of the myth, though one wonders if it is seen in the same light in Manchester, where Schuster was succeeded by Rutherford, and he in turn by Bragg and then by Blackett. It was in Manchester that the atom was born and first disintegrated, yet to the world at large it is the Cavendish that stands for British physics in that period. This is not the only example of the compelling hold that Cambridge exerts on the emotions of its alumni, and it is a self-perpetuating process whereby in due course the old boys send their best students back to seek their fortunes. The reputation of the Cavendish rests partly on what its professors have done, but more securely on what its students and junior staff are doing. So many of the country's most talented students are attracted to Cambridge by its reputation, to be joined, those who stay for research, by so many equally promising graduates from elsewhere, that the head of department's task is to encourage and to criticise, not to dominate. The conventional picture of Rutherford as something of a one-man band is quite misleading. It ignores the contributions of Chadwick and many others too numerous to mention, who proceeded to chairs and spread the Cavendish gospel of nuclear physics to the wide world; it also ignores the presence of Appleton, Bernal, Kapitza and G. I. Taylor, some of those who benefited from Rutherford's support without being drawn into his orbit.

Nevertheless, in comparison with the laboratory we now know, Rutherford's was an archaic monolith that could not survive the expansion of physics after the second world war, and Bragg soon recognised that the time had passed when one man could oversee the whole research effort. Inevitably he was conscious of stepping into a giant's shoes, for it was many years before the Cavendish could free itself of the private feeling, and the world's expectation, that nuclear physics was the field it ought to cultivate above all others. But Bragg seized on the essential point that ideas are not the privilege of the leader but spring from the community of workers, and his decision to share responsibility among a number of virtually autonomous groups led to such successes as ultimately laid the ghost of the past. It was the seeds planted in the thirties by Kapitza, Bernal, Appleton, and Ratcliffe that grew in those years, so that by the end of Bragg's tenure Low Temperature Physics, Crystallography (especially what was to become Molecular Biology) and Radioastronomy were vying with Nuclear and Particle Physics to attract the best students. Devolution was complete; the laboratory was three times larger than at Rutherford's death, and its ability to contribute at the frontiers of research was now extended over a much broader field.

At the same time a certain weakness was becoming apparent. The experimental approach which we have traced to J. J. Thomson had developed into something of an antimathematical attitude; the followers of the prewar physicists, who had been amateurs in the best sense, were in danger of becoming merely amateurish in an increasingly professional world. And not only through disregard of essential theoretical techniques, but equally through nostalgia for the string and sealing-wax days when experiments were cheap and quick and, above all, for individual efforts. Thus, though some might have found a paradox in Mott's election to an experimental chair, and others welcomed it as a return to the ideals of Maxwell and Rayleigh, it is better seen as the recognition of the need to abandon parochial attitudes, such as the hope that physics will remain accessible to intuition and robust commonsense, with mathematics as an optional extra. Equally it was essential to realise that modern problems demanded modern equipment. Simplicity is for the man of genius; most of us have to do it the hard way. However much it may have wounded the pride of those who saw the Cavendish as something apart, it could only have been harmful to pretend that any single laboratory can go it alone nowadays. There will be local

Lord Rutherford talking softly to J. A. Ratcliffe in the 1930s.

traditions and national tendencies, but only as minor variants of an international style with, for example, British physics still leaning towards the experimental approach in contrast to the more mathematical tendency of the United States and Japan.

In keeping with this general trend many of the best contributions of the Cavendish in the last 20 years have been founded on technical innovations. The invention and exploitation of aperture synthesis for radiotelescopes, and the design and marketing of Sweepnik, the automatic scanner, are two very different examples of recent work in the old Cavendish style. Nor are there lacking descendants of the pre-war amateurs, who eschew the beaten track and find more scope in opening up new lines, where observation and measurement get little guidance from established formalism. If we ask which type of work seems to be more highly regarded, the answer is rather disconcerting. For we smile at Rutherford's division of science into nuclear physics and stamp collecting, not recognising all round us the modern counterpart in the esteem we accord to mathematical analysis and, at best, the grudging respect for the accurate description of phenomena.

In looking to the future we could do worse than ponder for a moment the danger that always theatens physics of degenerating into scholasticism, of valuing the formal structure above all, especially if it can be disguised as ultimate truth. No one, of course, will dispute the mastery of those who have contributed to our deeper knowledge of the fundamental laws, and there is no physics laboratory but is richer for the presence of a leader in these studies. It is another matter, however, for students to be seen switching off their attention when the lecturer embarks on a discussion of observations that do not fit into any tidy pattern; and we are all too familiar with the way in which, given the choice, the brightest students choose theoretical physics, leaving the more experimental options for the less gifted. This is the legacy of a generation of professional research workers whose collective learning has established a standard which demands of all recruits such detailed formal knowledge as will leave them no time and, worse, no desire to tread paths where the signposts are few and uncertain.

This is one of the challenges which a laboratory like the Cavendish should attempt to meet. It has enough of a reputation to justify minor eccentricities of philosophy, and because of this, as well as the quality of its students, perhaps it has a greater responsibility than most to transit its version of the real nature of the subject. Its reputation never rested on knowing what everyone else had done, but on what its own members did, and how they inspired their students with the excitement of being a physicist. To carry on doing good research should not be too much of a problem, given that it is essentially a matter of catching and keeping as many as one can of the most ardent spirits, and providing the opportunity and encouragement for them to show what they are made of. But to carry this inspiration to the undergraduate level, where the need is greatest, is much harder than research—the urge is less, the praise fainter—and it is here that effort is really needed. To take a detached view, it could not be said to matter very much if most of the outstanding problems of physics were to remain unsolved. Yet it matters that we should continue to try to solve them, and discover new realms to explore, if only to renew in ourselves, and pass on to others, the assurance that physics is much more than a collection of laws whose application is a matter of knowledge and routine. For physics is, besides, a living craft of hand and mind which is transmitted more by example than by rote. Embodying as it does a technique essential to fight the material problems of the world, it must continue to be taught, and taught as a craft. There are countries whose universities teach that science is what the textbooks say, and reduce their students to intellectual sterility; and there are not lacking in this country influential men who would promote the same disaster here, believing innocently that academic research is an expensive luxury. The challenge of our times is not to assert, but to prove, that this is a dangerous illusion. If the Cavendish has a role to play, it is once more its traditional role—to be in the forefront of the battle.

international news

Counting the cost at Flixborough

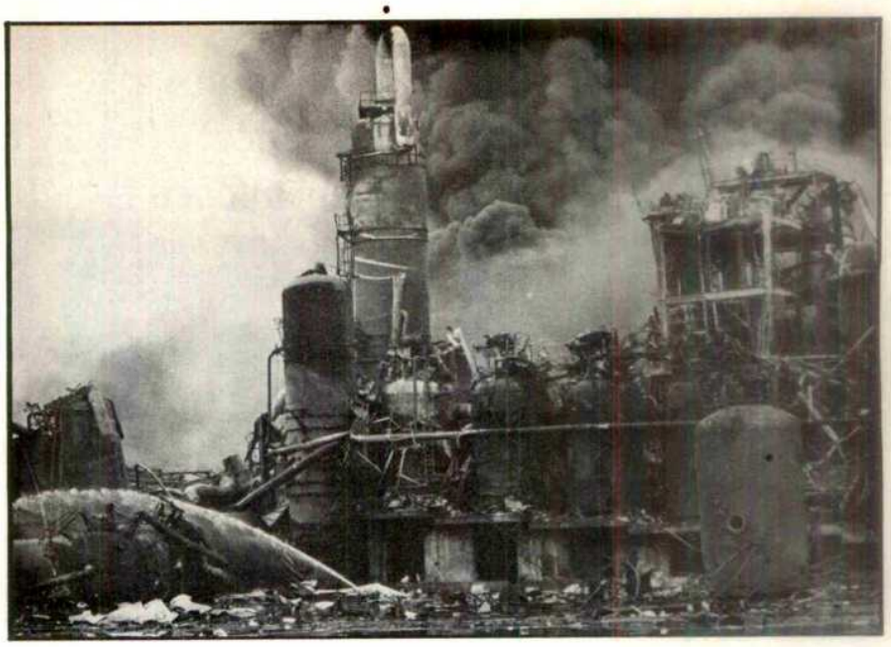
by John Wilson

TWENTY-EIGHT people killed, more than one hundred injured and upwards of £70m damage done to plant and surrounding property are the results of the most devastating explosion in peacetime Britain. It happened on May 4, at the 60-acre Nypro chemical factory in the village of Flixborough, Lincolnshire, which produces caprolactam—used in the manufacture of Nylon 6—and was caused by the sudden escape of a large quantity of cyclohexane vapour. The plant, owned jointly by Dutch State Mines (DSM) and the National Coal Board (NCB) was the sole producer of caprolactam in the United Kingdom. Its closure will affect 30,000–35,000 jobs throughout British industry to varying degrees.

A most disturbing aspect of the disaster is the damage outside the factory gates—thirty families have had to be rehoused—and questions are being asked in parliament and elsewhere about the safety of other large chemical installations in Britain, and indeed throughout the world (Nypro owns similar plants in Holland and Augusta, Georgia). The Secretary of State for Employment, Mr Michael Foot, has ordered a public inquiry into the disaster and the British Chemical Industry Safety Council are to review its findings. Meanwhile, Mr Jack Jones of the Transport and General Workers Union has said that the union will hold a separate inquiry of its own. Twenty-one of the dead were members of the union and Mr Jones believes that the survivors will talk more freely to their own union-appointed investigator.

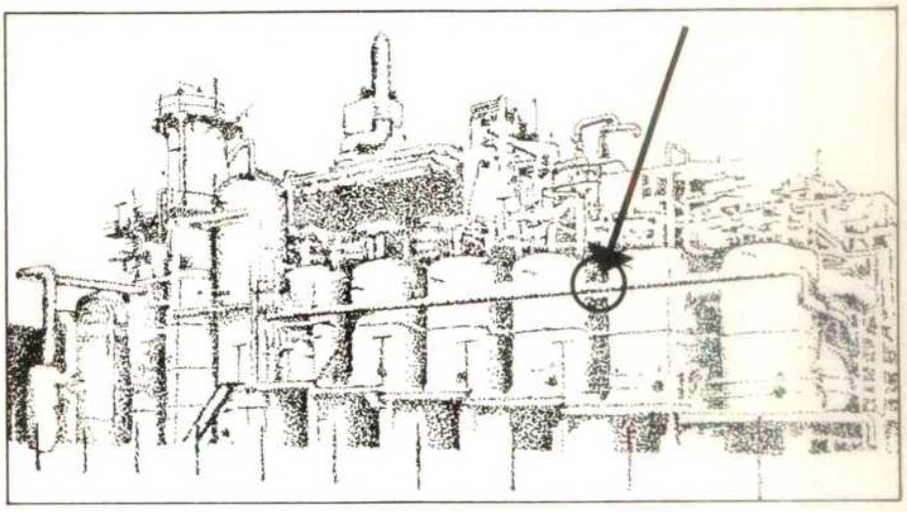
But more than a week after the disaster, explosions were still taking place on the site and firemen had not penetrated through the pools of dangerous chemical to the control room where many vital records were kept. It will probably be a long and difficult task to reconstruct exactly what happened.

What is now almost certain, however, is that the escape of cyclohexane vapour occurred at that part of the plant concerned with the oxidation of cyclohexane to cyclohexanone oxime, an intermediate product. High temperatures and pressures are involved in this process. One of the units was under repair at the time and a bridging pipe is thought to have fractured, although how the gas ignited is not yet known. But Mr Leslie Grainger, NCB board member for science, says that the way the gas escaped is more important than its ignition. In spite of searches for cigarettes and matches, the banning of motor vehicles and the issue of special anti-static clothing, most experts are agreed that the risk of a random spark cannot be entirely eliminated. The effects of any explosion, however, can be minimised by the design of the plant. The established practice of piping volatile material in the open, in the hope that any leak will be dispersed, must now be revised.



Flixborough: no rebuilding?

The greater the degree of physical connection between various processes at risk, the greater the danger that more than one unit will become involved in an accident. Even the siting of other processes, the manufacture for hydrogen, for example, may be vital in an emergency. The Nypro control room and laboratories were built in the centre of the site, between the oxanone processes and the hydrogen plant. Obviously some degree of connection is necessary—that is what a petrochemical complex is all about—but there must come a point when safety factors outweigh engineering expediency. The difficulty, says Mr Grainger, is to maintain the economic links without the physical ones.



The NCB became interested in the Flixborough venture when it was seeking an outlet for its crude benzol (a source of cyclohexane) produced at coke ovens up and down the country. Its opportunity came when Fisons Ltd, the fertiliser manufacturer, withdrew from partnership with DSM in 1971. By December 1972 a new £15 million extension to the plant was completed, producing caprolactam from cyclohexane; up to that time phenol had been used as a raw material.

The cyclohexane was oxidised to cyclohexanone and the oxime formed by the addition of ammonia and sulphuric acid. Ammonium sulphate used to be a principal by-product of this reaction—which is why Fisons were involved—but was later recycled as phosphoric acid. The oxime was finally converted to caprolactam by Beckmann isomerisation.

A third phase of expansion was to have been commissioned later this year but whether that expansion would have used phenol or cyclohexane had not been decided at the time of the explosion. Mr Grainger says that there is now an emotional argument against the cyclohexane technique but hopes that any further decision will be based on rational grounds. Whatever process might be used in the future, there is strong local opposition to rebuilding the site at Flixborough. Comparisons are inevitably drawn in any industrial disaster of this size with the safety of nuclear installations. These have greater safety restrictions placed upon them and in Britain they need the approval of the Nuclear Inspector, whose decision is final. But a chemical plant may be built without consulting anyone except the local planning authority, who usually have little expert opinion to draw on. The Factory Inspectorate has no say in the matter until the plant is erected. At a time when the safety of nuclear power plants is in question, this seems to be a double standard.

THE oxanone plant at Flixborough, where the leak which caused the fatal blast is thought to have occurred. The picture above shows the cyclohexane containers after the explosion. One tank had been removed from its place for repair, and in the space it had formerly occupied a bridging pipe was used to connect the remaining tanks (location arrowed in drawing below). Nypro Ltd refused to comment on the suggestion that temporary piping was the source of the leak. They are waiting for the report of the Factory Inspector which will be published later this year.

Teaching for safety in technology

by Roger Woodham

WHATEVER the precise cause of the Flixborough disaster may turn out to be, Sir Brian Flowers, Rector of Imperial College, London, and Chairman of the Royal Commission on Environmental Pollution has set wheels in motion within Imperial College to find out whether teaching there places sufficient emphasis on reducing technological hazards of all kinds to an absolute minimum. Sir Brian expressed concern in a speech in April that "what is regarded as an acceptable disaster is increasing all the time, whether it is a hijacking or a motorway pile-up . . . It seems strange that increasing acceptance of technological failures should seem to coincide with increasing intolerance of environmental pollution." So the Flixborough disaster was the catalyst but not the cause of the setting up of a working party under Professor A. R. Ubbelohde, Head of the Department of Chemical Engineering and Chemical Technology at Imperial College.

Professor Ubbelohde said last week that the ultimate objective must be to imbue engineers—be they recent graduates or those with industrial experience returning to Imperial College for post-experience courses—with the "concepts of safe design". He also predicted that the monitoring of potential hazards, preferably by two independent methods, will receive much more attention in the future.

Sir Brian says that all too often "clever economic solutions have come before the safe solution which respects life." Modern technology should be fail-safe (so that alterations in any parameter of the system make it safer) but it is not, he said.

The working party has three months to submit a report and it seems unlikely that the document will stay internal to Imperial College for very long.

Gloomy outlook for Project Independence

Colin Norman, Washington

EVER since Arab oil producers shut off oil supplies to the United States late last year, President Nixon has been telling the American public at every opportunity that his Administration is committed to a pell-mell drive to make the United States self-sufficient in energy. Called Project Independence, the programme was launched with a flood of rhetoric in November 1973, and President Nixon still maintains in his public announcements that the goal will be met by 1980. But last month, two independent studies concluded that the effort will be extremely costly, and that self-sufficiency will probably be unattainable—even by 1985.

With much of the press distracted by more topical matters, the studies drew little public attention but they provide the strongest evidence so far that the United States will have to rely on imported oil to meet its energy demands for at least another decade and probably for long after that, in spite of massive investment in research and development and capital equipment.

Prepared by the Massachusetts Institute of Technology's Energy Laboratory and the National Academy of Engineering (NAE), the studies analysed Project Independence from two different standpoints but both reached essentially the same conclusion. The MIT study argued that energy self-sufficiency can only be bought with another sharp increase in the price of domestic oil which, in the short term, "would yield little more than an income transfer from consumers to producers", while the NAE study concluded that it will take capital expenditure amounting to about $600,000 million over the next 10 years and government intervention in the energy industry to make the United States independent of foreign energy supplies by 1985.

If anything, the NAE study paints the bleaker picture, for it simply examines what will be needed from each energy sector between now and 1985 to give Project Independence a chance of success, and it comes up with some pretty sobering conclusions. The burden of the study's message is perhaps best summed up by the following statement in the NAE report: "Achieving the complete range of programs described in this report by 1985 is not considered . . . to be of high probability. Even if it is accomplished, the United States would be buying time. For beyond 1985 there looms the ominous prospect of even greater demands for energy from ever-increasing and ever-rising expectations from home and abroad".

Although the Administration's statements about Project Independence have so far been unencumbered by a definition of what actually constitutes self-sufficiency, and President Nixon seems to pay little attention to advice from his top energy officials that 1980 is a totally unrealistic date to expect the United States to become independent of foreign energy supplies, the effort required will be staggering.

For a start, energy supply and demand predictions made before the energy crisis began to bite indicated that by 1985, Americans would be consuming the equivalent of 58 million barrels of oil every day, while domestic supplies would amount to little more than 40 million barrels. Somehow, therefore, Project Independence will have to contend with a shortfall of about 18 million barrels of oil equivalent a day within the next 10 years.

According to the NAE study, this could be achieved by an aggressive conservation programme and a crash effort, beginning this year, to exploit all domestic energy resources in the United States. The conservation effort could be expected to reduce demand by about 8 million barrels a day, while the development efforts would entail doubling coal production, massive strip mining in the Western United States, increasing nuclear power output so that fission reactors generate a third of the total electricity output in the country (up from less than 1 per cent last year), increasing oil and gas production by 25%, and establishing entire new industries to produce synthetic petroleum and natural gas from coal and oil from shale.

Apart from the $600,000 million price tag, there are several major obstacles which are likely to prevent Project Independence from being a success, however its goals are defined. For one thing, such a massive development of energy resources is likely to be achieved at the expense of considerable destruction of the environment, and for another, the NAE study suggests that there is likely to be a considerable shortage of skilled manpower, materials and equipment. In short, Project Independence is likely to be an expensive failure when measured against President Nixon's public announcements.

As for each energy sector, the NAE study comes up with the following conclusions:

- Coal. The United States has about one third of the world's coal reserves, and these are likely to provide the bulk of any increase in domestic energy output in the next decade. According to the study, output must be doubled by 1985, chiefly by opening up large federally owned areas of Montana and Wyoming for strip mining and expanding underground mining in the Eastern United States. By itself, an increase from 660 to 1,260 million tons a year over the next decade doesn't sound too daunting a prospect, but when translated in terms of the physical facilities which will have to be added to the coal industry, the undertaking is staggering.

"Stated another way", the report says, "on the average one new deep mine and one new surface mine must be brought into production every month for 10 years. In contrast, only 13 mines of greater than 2-MTPY (million tons per year) production were opened in the 10 years from 1960 to 1969".

Equally startling are implications for transporting coal to power stations and other users if output is doubled. The NAE study suggests that 60 new rail-barge systems, between 100 and 150 miles long and each capable of handling 2 MTPY, will have to be constructed in the eastern United States, and 70 3-MTPY systems of between 1,000 and 1,200 miles will have to be constructed in the West. To haul the stuff, 8,000 locomotive units and 150,000 hopper cars, each of 100 tons capacity will have to be built. At present there is a severe shortage of hopper cars.

- Oil and Gas. Last year, more than 75% of energy requirements in the United States were supplied by oil and gas, but increases in domestic production will only come from very costly new sources such as offshore deposits in the Atlantic and in Alaska, and the NAE study predicts that at best an increase of about 25% can be expected from United States sources. To achieve even that increase would cost about $180,000 million over the next decade: it would require an average of 58,000

new wells to be drilled each year—twice the rate in 1973—new methods for recovering oil from marginal wells would have to be developed and environmental problems associated with offshore production would have to be resolved. But even if all those programmes are successful, domestic oil and gas production would reach only about 27 million barrels per day equivalent in 1985, which is about 1.6 million barrels short of the demand in 1973.

- Electricity production. The total generating capacity of the United States electrical industry in 1973 was about 435 million kW and the NAE study concludes that this could be doubled over the next 10 years with capital investment of about $300,000 million. First, nuclear power would have to be expanded greatly above present projections, to reach about one third of total electrical capacity by 1985. This will require between 2 and 3 new nuclear units to be built every month, uranium production would have to be expanded by a factor of 6, between 30,000 and 40,000 plant operators and maintenance personnel would have to be trained, 30 reactor pressure shells and turbine generators will have to be manufactured and delivered each year, and the time it takes to license and construct nuclear plants will have to be greatly reduced from the present 10-year average.

Another key programme in the electrical energy sector is the expansion of coal-fired power station capacity. This, the NAE study suggests, will require five oil-fired power stations to be reconverted to coal every month for the next four years, two new 700 MW stations will have to be brought on line each month for the next decade, and 10 new plants will have to be constructed to produce medium-BTU gas from coal to fuel 50 power stations which are now fired with natural gas. All of that, however, would have to rely on the development of new technologies to control the emission of sulphur dioxide from power plants, or alternatively, environmental regulations would have to be greatly relaxed.

- Synthetic petroleum, natural gas and shale oil. In order to meet the predicted shortfall in oil and gas, it is estimated that new technologies must be developed to produce the equivalent of 1.1 million barrels of oil per day from coal gasification, 0.6 million barrels per day of synthetic petroleum from coal, and 0.5 million barrels per day of shale oil. Apart from a massive research and development programme, it will take a capital investment of between $16,000 and $22,000 million for the coal conversion projects, and between $3,000 and $5,000 million for the shale oil production.

The NAE analysis points out that the cost of those processes is likely to deter early production, and constraints such as the availability of water and environmental regulations are likely to set a limit on the ultimate capacity of some of the processes. And the MIT study is even more pessimistic, for it states that at present oil prices, there is insufficient financial incentive for the energy industry to move into those fields. Both studies therefore recommend that the federal government should provide a variety of incentives such as guaranteed prices, tax breaks and joint financing of development plants to bring the technologies on line as early as possible.

- Conservation. The prospects for the success of Project Independence hang to a great extent on whether or not the United States' insatiable appetite for energy can be curbed. Although the rapidly increasing cost of energy will work to reduce demand through the normal market forces, it is clear that the federal government must take a strong lead in encouraging conservation by a variety of measures such as allocation of funds to mass-transit systems, promoting research and development on more efficient ways to produce and transport energy, and by continuing such measures as speed limits on highways and encouraging car pooling.

The NAE study identifies four chief constraints which lead to its prediction that it is highly unlikely that all the projects necessary to achieve energy independence will be carried out. First, the capital investment required—$600,000 million over 10 years—is almost double the present investment rate in the energy industry, and it should be compared with the total investment in all industrial plant and equipment of about $100 million in 1970. Second, the availability of water is "a serious concern for producing oil from shale or synthetic fuels from coal". Third, environmental damage resulting from strip mining—particularly in the remote Western coalfields—and from burning large quantities of coal will have to be overcome by the development of new technologies, otherwise environmental regulations will have to be relaxed. And finally, a huge manpower problem could arise since several hundred thousand people will have to be recruited and trained in the energy industry during the next decade; in particular, the NAE study points out that enrolment has been dropping in university engineering courses.

One thing is clear from the study—a number of complex decisions must be taken by the federal government within the next year, and a coherent national energy policy must be formulated. So far, however, neither the Administration nor Congress has matched Presidential rhetoric with concrete action.

ESRO awards Spacelab contract

THE European Space Research Organisation has decided to award a contract worth approximately 180 million accounting units* for the design and development of the manned orbital laboratory Spacelab to VFW-Fokker/Erno of Germany, as prime contractor for a European industrial team whose composition reflects the financial contributions to the Spacelab programme by participating ESRO member countries. The unanimous decision was made by ESRO's administrative and finance committee, composed of member country delegates, at a meeting in Paris. It followed six weeks of evaluation by ESRO officials of two industrial proposals of high technical quality.

This six-year contract provides for the delivery of one Spacelab flight unit, fully qualified and ready for the installation of experiments, by April 1979. Other main deliverable items are two engineering models, three sets of ground support equipment and initial spares.

The Spacelab project is the most important cooperative programme between ESRO and NASA. ESRO is responsible for the design, development and construction of the laboratory, which NASA will launch in its space shuttle and operate. The first Spacelab launch is scheduled for early in 1980. NASA will soon commit itself to purchase a second Spacelab unit from ESRO and has indicated its intention to purchase such additional Spacelabs as may be required.

Unlike earlier space laboratories, Spacelab will be reusable. It will be designed for 50 missions of a week to a month, or a nominal life of 10 years. It will enable, for the first time, scientists, engineers and technicians to travel and work in Earth's orbit without undergoing intensive astronaut training. Spacelab is designed to reduce significantly the cost and time needed for space research and its applications, and to provide to a large number and wide variety of American and European users a versatile laboratory in which experimenters can work in comfort.

* At mid-1973 price levels 180 MAU is equivalent to approximately £95 million, FF 1,000 million, DM 578 million and $226 million.

Earth scientists

SIR,—'European earth scientists disunite', an article by Peter J. Smith in your issue of April 12 is erroneous and misleading; we are concerned that such an article should have appeared in *Nature* without an attempt to check the facts.

The main tenor was implication of lack of coordination between the organisers of a forthcoming meeting in Reading of European Geological Societies (the Geological Society and the University of Reading) and the European Geophysical Society. In fact the minutes of the first meeting of the Policy Committee for the Meeting of European Geological Societies which is to take place from September 8-12, 1975, were sent in July 1973 to the Secretary of the European Geophysical Society at the Royal Society. A letter with his comments was received. It was certainly not "more or less by accident" that he discovered that there would be such a meeting. In December 1973 a special letter was sent to the President of the European Geophysical Society, with a copy to the Secretary, inviting participation of members of EGS and requesting their views and suggestions for topics for discussion. The letter was acknowledged by President Morelli welcoming the chance for cooperation, and expressing the hope that many members of the EGS would be interested in attending the Reading meeting.

For one whose professed anxiety is about the unity of earth science (that is, of geology) Mr Smith lays a surprising amount of emphasis on a distinction between geophysics and geology. We would expect him to recognise, as we have for many years, that geophysics is a necessary and important part of geology. Phrases such as "there being no such thing as the geology of the core" make semantic nonsense to stratigraphers, mineralogists and sedimentologists like us. Of course we agree that geophysicists, tectonicians, geochemists, palaeontologists, petrologists and the rest need to talk to one another: that is the object of the projected Reading meeting in 1975; we do not, however, see it as a matter for geophysicists on the one hand and "geologists" on the other. The theme chosen for the 1975 meeting, 'Europe from Crust to Core' is designed to secure the widest possible interdisciplinary discussion. As to the formation of a Pan-European Society of Earth Scientists, that is not the immediate object of the exercise, but if some of those attending wish to discuss such a possibility, so well and good.

Reply from Chile

SIR,—In your journal (March 29) you published a letter sent to you by well known scientists who referred to the "dramatic conditions of the Chilean academic community". As these scientists have great influence in the scientific community, I must reply to such a letter.

I was in fact nominated as Rector of Universidad Católica de Chile by the Junta Militar de Gobierno, which designation was confirmed by a Decree of the head of the Catholic Church in Chile and Gran Cancillar of this University, Cardinal Raúl Silva Henríquez. Nothing said in the letter referred to, corresponds to the real situation in this University since the day I assumed office, early in October, 1973.

Contracts of academics are not provisional as the letter suggests. It is true that some of them have been dismissed although no special Commission has existed for this purpose. They were dismissed because they simply abandoned their job or because they never anticipated in the academic life of this University or any other but preferred political activities instead of doing the work they were paid for.

In any case, the number of academics dismissed from this University is less than the figure of 65 quoted in the letter. This is out of a total of over 2,000 teachers. In all cases of dismissal full legal compensation has been paid. None are natural scientists; they all belong to the social sciences, mainly sociology and political science.

None of the 11,500 students in this community has been dismissed and so there has been no need of reregistration.

With regard to the staff in prison or executed, some teachers and administrators have indeed been questioned. Very few are still in prison (only 5) and legal procedures are followed to clarify their responsibilities for the crimes of which they are accused, according to traditional Chilean law. They have been allowed legal defence, as it is a long standing custom in Chile which nobody here has forgotten. As to the executions which they claim have happened, I would like to hear of one member of this University who has suffered, for I know of none.

As to the departments which have been dismantled, none of the examples given in the letter has occurred here. No Faculty or Institute has been closed except for two political centres whose Marxist political inspiration was dedicated to public indoctrination.

Nevertheless, I can say that those who judge us seem to ignore the facts and to forget our previous history. They have not considered at all what has really happened in the University. They have not considered that the Supreme Court and the Congress had previously declared the former government illegal, nor that our Armed Forces have historically been politically neutral, nor the people's claim over the last two years to remove the Marxist régime which was destroying all our rights and most beloved traditions. Scientists particularly, should be aware that proof is required before any decision. Nobody should say anything which he may regret the next day; nobody should allow themselves to be the instrument of others hidden intentions.

In this sense, I trust that time and history will establish what really happened in this country, despite all intentional and international campaigns against Chile.

JORGE SWETT MADGE
Universidad Catolica de Chile, Santiago, Chile

Penicillin

SIR,—Your article (*Nature*, May 24) on cancer research by Brian Ford contains the statement that it was the war effort and directed research which gave us penicillin. This statement is incorrect. The reinvestigation of penicillin which led to the discovery of its curative properties was started in 1938, well before the outbreak of the war, and its aim was not the practical one of discovering a new chemotherapeutic agent.

Rabbit–scallop transplants

COMPARING and contrasting animals of widely different form is a common pastime for muscle specialists, since in their field similarities generally outweigh differences and there is much common ground for detailed correlation. In general, muscle contraction takes place by some kind of sliding filament mechanism, that is, by relative movement of actin and myosin filaments, and regulation of the system is mediated by the level of calcium ions. Within this fundamental framework, however, there is considerable variation of detail in the Animal Kingdom—in the way, for example, the calcium control is exercised. In vertebrate skeletal muscle, changes of calcium level affect the muscle activity by modifying the troponin and tropomyosin components of the actin filaments, whereas in the muscles of molluscs and some primitive invertebrates myosin and not actin is controlled. In some invertebrates there is dual control, that is, both types of filament are involved in regulation. Evolutionary forces are clearly at work here, and the understanding of problems of animal specialisation and adaptation provides an interesting background to the more fundamental task of elucidating the molecular basis of muscle contraction.

Myosin is a protein with a long tail portion and two globular heads. From the heads may be dissociated polypeptides of relatively low molecular weight, the so-called light chains. In rabbit skeletal muscle myosin there are two classes of light chains, one class released by alkali and the other by DTNB (5,5′-dithiobis-(2-nitrobenzoic acid)). The alkali light chains have been shown to be involved in the enzymatic activity of the myosin, but the function of the DTNB light chain has long remained a mystery. Scallop muscle myosin, on the other hand, has light chains released by EDTA, and without these chains the splitting of ATP by the myosin–actin system is not susceptible to changes of calcium, that is, the myosin becomes 'desensitised'. Is it possible, therefore, that the DTNB light chain in the rabbit has a role analogous to that of the EDTA chain in the scallop? If it does play a part in calcium regulation, how significant is its function relative to the actin-linked control? Perhaps the existence of the DTNB light chain is vestigal, an evolutionary relic of the more primitive scallop type of myosin regulation that has been usurped by sophisticated actin control? To test these ideas, Kendrick-Jones (see page 631 of this issue of *Nature*) has carried out molecular transplants in which the DTNB light chain from rabbit is grafted onto desensitised scallop myosin. Sure enough, the sensitivity is retrieved. This is a most remarkable result, and a triumph for advanced protein techniques which, together with the investigator's skill, can bridge a gap that was many millions of years in the making.

The DTNB light chain restores the calcium sensitivity more fully to the intact scallop myofibrils that have been treated with EDTA than to preparation of pure scallop myosin similarly treated. There is no evidence that the DTNB reacts directly with any protein other than the myosin, however, and it is possible therefore that actin in the myofibrils may have an indirect effect by stabilising the myosin in some way. Experiments with radioactivity labelled DTNB light chains show that one mole is bound per myosin molecule. Since the myosin molecule normally releases one mole of EDTA light chain, and this must be removed before the DTNB chain will attach, the binding sites for the two polypeptides are likely to be essentially the same. The binding of the DTNB light chain is tight and specific, and the other rabbit light chains—the ones released by alkali—cannot be made to bind to scallop myosin or to affect its calcium sensitivity.

Since rabbit turns on scallop, what can the latter do in return? Kendrick-Jones has not omitted this intriguing alternative, but, disappointingly, the full reciprocal relationship is not established. Although radioactive labelling shows that the scallop EDTA light chain will bind to rabbit myosin that has been treated with DTNB, the myosin does not then become calcium sensitive. Still, the fact that the two chain types are interchangeable is interesting enough, and the interest is intensified by the knowledge that their chemical structures have no obvious similarities.

There is little direct evidence for myosin playing a part in the regulation of vertebrate skeletal muscle activity by calcium. X-ray diffraction of stretched living muscle has indicated that the positions of the myosin cross-bridges alter when the calcium level is changed. When, however, the myosin is extracted from the muscle, its ability to split ATP in the presence of pure actin is unaffected by the calcium level, though it does bind small amounts of calcium. The fault may lie here in the extraction and purification procedure.

Some living organisms have myosin-linked regulation, some actin-linked, and some have both. The transition and gradation between these regulatory mechanisms, their evolutionary significance and what particular physiological advantages are conferred by the possession of one or other or both remain fascinating questions. It could be argued, however, that the scope at least of the problem has been encompassed by Kendrick-Jones's successful matching of the light chains separated by aeons, and union of two animals sufficiently dissimilar to startle even Edward Lear.

E. J. O'BRIEN

Aspects of the asthenosphere

IT may be a cliché to say that the Earth's asthenosphere exerts a profound influence on the crust and lithosphere above, but it is neither less true nor less important a statement for that. Irrespective of whether convection currents are limited to it or go deeper, the asthenosphere clearly plays a crucial part in the horizontal motion of continents and ocean floors; it is the source of at least some of the material which finds its way from the mantle to the Earth's surface, and is closely related in composition to that part of the mantle which provides the rest; and it is the ultimate means by which a crust with a changed load may achieve isostatic equilibrium. In other words, it governs the behaviour of the upper layers of the Earth to such a degree that the determination of its physical and chemical properties can be safely said to be one of the genuinely fundamental problems in the Earth sciences.

And for obvious reasons it is a problem both difficult

and complex—characteristics which provide considerable opportunity for disagreement. On the other hand, there are some things that can be said with little fear of contradiction. Presumably few people would now object to, for example, the general definition of the asthenosphere as a layer with no enduring resistance to a shearing stress and thus with a finite strength small enough to be neglected (Le Pichon *et al.*, *Plate Tectonics*, Elsevier, 1973). It is interesting to note, however, that modern as this difinition may sound, the possibility of flow inherent in it had actually been implied by the acceptance of the principle of isostasy more than a century ago; and it was the problem of isostasy which later led Barrel (*J. Geol.*, **22**, 441 and 655; 1914) to incorporate the flow property into a layer model involving a 'lithosphere' and an 'asthenosphere'. In other words, by a curious coincidence the concept of an asthenospheric layer came about independently at almost exactly the time that Wegener was proposing continental drift, the phenomenon that would later require the characteristics of the asthenosphere to provide a convincing mechanism.

But it was to be a long time before the asthenosphere would be properly defined in non-isostatic terms, even though the process began with Gutenberg's early suggestion (*Z. Geophys.*, **2**, 24; 1926) that the general monotonic increase in seismic velocity with depth in the Earth may not be applicable to the uppermost mantle. Much later, in the light of many more and more modern seismic investigations, Gutenberg (*Physics of the Earth's Interior*, Academic Press, 1959) was able to propose the existence of an upper mantle low velocity zone having a minimum P wave velocity at a depth of about 100 km and a minimum S wave velocity within the depth range 100-200 km, the maximum decrease in velocity being a few percent for each type of wave but slightly greater for S waves than P waves. It now seems doubtful whether the P wave channel is universal, but the more pronounced S wave low velocity zone has been confirmed. It probably begins at a depth of 70-80 km beneath typical ocean basins and in the range 110-130 km beneath continental shields, in each case ending at a depth of about 250 km (Press, *J. geophys. Res.* **75**, 6575; 1970). The viscosity in the vicinity of this zone is also apparently low, both Gordon (*Geophys. J.*, **14**, 33; 1967) and McKenzie (*Geophys. J.*, **14**, 297; 1967) having estimated a value of about 10^{21} poise which thereafter rises very rapidly with depth. In summary, then, the asthenosphere seems to be a relatively thin upper mantle layer which varies somewhat in depth and thickness according to the tectonic environment above, in which seismic velocity is anomalously low (and seismic attenuation high), and in which viscosity is also particularly low.

But how does this peculiar combination of properties arise? According to Ringwood (in *The Earth's Crust and Upper Mantle*, American Geophysical Union, 1969), there are several ways in which zoning in the upper mantle might take place. One (mineralogical zoning) is based on the ability of material with his hypothetical 'pyrolite' (1 part basalt, 3 parts dunite) composition to crystallise into four distinct mineral assemblages with different physical properties. Which of these will form at any given time and place will be determined largely by the intersection of geotherms with the assemblages' stability fields; in other words, the assemblage forming will be the one stable at the relevant temperature and pressure. And since temperature and pressure vary with depth in the mantle, so will physical properties. A second possibility is chemical zoning in which "the extensive fractional melting and upward segregation of low-melting components that is inferred to have occurred beneath highly evolved con-

Recognition of *lac* initiator

PROTEIN synthesis in *Escherichia coli* begins after the ribosome and transfer RNA_f^{Met} have bound to a region of the messenger RNA containing the initiator triplet codon. An intriguing question is how the machinery recognises and selects the correct AUG (or GUG) codon out of others that may be fortuitously or otherwise present. Maybe a specific sequence of bases is recognised or maybe there is some aspect of the secondary structure with a recognisable shape.

An approach to this problem is to make use of the fact that initiation complex is stable in the absence of other charged tRNA species so that protein synthesis is prevented from taking place. It has been found that a region of the messenger RNA is protected from attack by endonucleases by the bound ribosome and it is tempting to believe that these protected regions contain the features that are recognised as well as the initiator codon.

The base sequence of several such ribosomal binding sites have already been published for various cistrons of various phages and a possible initiator triplet has invariably been found. In some of these sequences the protected sequence looks as if it could form a region of helical secondary structure with the codon in the loop, and it has been mooted that it is some aspect of this structure that is recognised by the *E. coli* ribosome.

This attractive notion seems to be confounded by work by Maizels (see page 647 of this issue of *Nature*). She had already reported the sequence of the first 63 bases of the lactose operon messenger RNA transcribed from the CAP-independent UV5 promoter mutant. The first AUG triplet occurs at positions 39-41 and is followed by 21 bases that code for the first seven amino acids of β-galactosidase. This suggested that translation might initiate at position 39 and that ribosomes should protect the surrounding region.

Maizels has gone on in her new article to sequence the region of this messenger that is protected by the ribosome in the initiation complex. The results gratifyingly show that the region around position 39 is indeed protected, though the precise length of the protected region depends on the activity and nature of the degrading endonuclease. It next turns out that no obvious secondary structure can be constructed with the codon in the loop.

The next step was to inspect the various ribosome protected regions obtained from the *lac* messenger and from the phages to see if common sequences are present. From this several generalisations emerge. First, there is always a nonsense triplet within 22 bases of the initiator codon, on the 5′ side; second, seven of the eleven sequences including the *lac* messenger show the quadruplet AGGA on the 5′ side; third, many of the sequences, again including *lac*, show a sequence PuPuUUUXPu (Pu is a purine and X is usually a purine). The significance of these findings is, however, further confused by the fact that these common subsequences do not occur in the same position relative to the initiator codon or even in the same order.

The question remains as to whether these results provide a tantalising glimpse at the requirements for initiator recognition or whether they are only fortuitous; for the possibility is still open that the binding of the ribosome to the protected region is not the primary event and that the recognition involves some other part of the messenger or even that the recognition process involves some other messenger specific factor.

E. G. RICHARDS

tinental regions results in zoning caused by layers which differ in chemical composition". In addition, regional variations in temperature–depth distributions will cause corresponding variations in elastic properties. In spite of these possibilities, however, any or all of which may play an actual part in the formation of the asthenosphere, the consensus is that they are not by themselves sufficient to account for, among other things, a decrease in S wave velocity from about 4.6 km s^{-1} immediately below the lithosphere to 4.3 km s^{-1} (or even 4.1 km s^{-1} in places) at a depth of about 100 km. This is why several workers, beginning with Anderson (*Sci. Am.*, **205**, 2; July 1962), have suggested that the low velocity zone implies a small degree of partial melting—a proposal which goes rather further than an earlier one to the effect that the low velocity part of the mantle is close to the melting point.

Since this suggestion was first made, the conditions under which a small but significant part of the mantle would remain in a state of partial melting have been examined in some detail. It soon became evident, for example, that the stability of a very small degree of partial melting would be difficult to maintain if the mantle were completely anhydrous. As Green (D.H.) and Ringwood have pointed out (*Beitr. Miner. Petrogr.*, **15**, 103; 1967), at pressures of 20-30 kb the melting temperature interval between the solidus and liquidus of olivine tholeiite and picrite is less than 100° C, and within this range dry pyrolite would probably become 30% molten. Even temperature fluctuations as small as 20° C would produce about 5% partial melting. In other words, for a dry mantle the degree of partial melting is very susceptible to temperature changes, making for an instability with which magma bodies would form and surface volcanism would occur on a greater scale than is actually observed. Or to put the matter another way, the assumption that partial melting occurs in the mantle because the geotherm rises above the dry solidus cannot be sustained because the geotherm would have to be finely controlled and constrained close to the solidus to prevent the production of too much liquid and the resulting instability.

So some stabilisation mechanism must be found; and one which has achieved a high degree of creditability in recent years is the presence of water. Numerous experimental studies have shown that even a very small proportion of water (say, 0.1%) will lower the melting temperatures of material thought to comprise the upper mantle by several hundred degrees, thereby increasing the interval between the solidus and the liquidus. The chemistry and mineralogy is quite involved, but the net physical effect of this increase is greater stability against temperature changes. After the occurence of a very small degree (say 1%) of partial melting—often termed incipient melting to distinguish it from the 5-30% partial melting required to form magmas—a comparatively large change in temperature will cause only a very small change in the degree of melting. And the fact that the amount of liquid produced varies little throughout a wide range of temperatures is widely thought to explain how a low velocity zone with little variation in properties can exist beneath a wide range of tectonic environments.

Details apart, however, what is clear from all this is that a great deal of thought and experimental work has gone into supporting the apparently simple proposition that the asthenosphere is a manifestation of incipient melting. This does not necessarily mean that the conclusion is right, of course—but at the same time, it does mean that anybody coming to the opposite view faces a difficult task in convincing others. In their article on page 617 of this issue of *Nature*, Green (H.W.) and Gueguen come to the opposite view. Whether their argument will be thought to carry the necessary conviction remains to be seen.

In the meantime, it is interesting to note the mild irony involved in the fact that Green and Gueguen come to their conclusion from a study of kimberlite pipes. The fact that kimberlite pipes (which occur in India, the United States and Siberia but are best known over about two million square kilometres of southern Africa) contain diamonds implies that the kimberlite magma originated at asthenospheric depths (pressures), or, as Green and Gueguen themselves argue, at lower asthenospheric depths. And the fact that they contain large numbers of xenoliths (genetically unrelated inclusions) acquired on the upward journey, not only of crustal rocks but also of material not known to occur in the local crust, implies that the 'unknown' xenoliths comprise a random sample of upper mantle rock types cut by the pipes. So the xenoliths are a valuable source of information on the composition of upper mantle materials (at least beneath stable continental regions)—materials whose studied behaviour led to the conclusion that the asthenosphere must be partially melted. But now Green and Gueguen have used the very same xenoliths (among other things) in quite a different way to show that the asthenosphere cannot be partially melted.

PETER J. SMITH

Magnetic superfluid

THE observation by Bozler, Bernier, Gully, Richardson and Lee of Cornell University (*Phys. Rev. Lett.*, **32**, 875; 1974) of a longitudinal nuclear magnetic resonance at the frequency which had been predicted by Leggett of the University of Sussex (*ibid.*, **31**, 352; 1973) suggests that theory is again starting to catch up with experiment in attempting to reach an understanding of superfluid ^{3}He.

For more than a decade theory had been well ahead in that a superfluid transition had been predicted, but had not been discovered experimentally. This prediction stemmed from an extension of the theory which Bardeen, Cooper and Schrieffer had devised (the BCS theory) to account for superfluidity of the electron gas in a superconducting metal, to describe assemblies of neutral particles, and liquid ^{3}He in particular. The basis of the BCS theory is the idea that, in the presence of an attractive interaction between themselves, the electrons can reduce their total energy by forming pairs with opposite spin and momentum. To break apart one of these co-called Cooper pairs requires a certain minimum amount of energy, so that any dissipative process which is unable to provide this minimum energy cannot occur, and flow of the electrons without dissipation of energy is therefore possible provided that a critical velocity is not exceeded. In the case of a superconductor the attractive interaction between the electrons, which is able to overcome their mutual Coulomb repulsion, arises through slight distortions in the lattice of positive ions in the region of each electron.

Like electrons, ^{3}He atoms also carry a net spin angular momentum of $\frac{1}{2}h$ and similarly, being fermions (unlike ^{4}He atoms), it is rigorously forbidden for more than one of them to be in the same state. Liquid ^{3}He is, of course, in other ways very different from a superconductor. In particular, there is no lattice and the atoms of which it is composed are electrically neutral. It was realised, however, that an effective attractive interaction might exist between two ^{3}He atoms if their mutual angular momentum was nonzero, so that a new form of Cooper pair might thus be created. This orbital angular momentum had to be quantised as lh, with l an integer, and a variety of suggestions was made concerning both the likely value of l and also the relative orientations of the two spins and the orbital motion of the pair which would give the lowest energy, and thus represent the most probable state of the assembly. Because such an assembly is composed of neutral atoms, the predicted state was referred to as superfluid rather than superconducting.

The observation in 1972 by Osheroff, a postgraduate

student at Cornell, that liquid ^{3}He under pressure undergoes two separate phase transitions as it is cooled below 3 mK seemed to indicate that the long predicted superfluid state had been discovered. Subsequent experiments at Cornell, La Jolla and Helsinki seem to have confirmed that both new phases of the liquid are indeed superfluids.

When a magnetic field is applied to normal liquid ^{3}He, above the superfluid transition temperatures, each nuclear spin has a choice of occupying one of two possible states separated by an energy $h\omega_L$, depending on whether it is parallel or anti-parallel to the field. The absorption of energy which occurs when electromagnetic radiation of frequency ω_L is applied at right angles to the magnetic field, is referred to as nuclear magnetic resonance (NMR), and is a consequence of transitions being induced between the two energy levels. It was found that as liquid ^{3}He cooled below the higher temperature phase transition into the so called A phase, the NMR frequency rose rapidly; and on reaching the second transition and entering the lower temperature B phase, the frequency suddenly reverted to the original value which is posessed in normal liquid ^{3}He. From these phenomena it was inferred that Cooper pairs in the A phase were formed with their spins parallel, producing a resultant spin angular momentum with consequent magnetic effects; but that those in the B phase were probably antiparallel, with no resultant spin and therefore no shift in the NMR frequency. It seems probable that in both the superfluid phases the orbital action of all the pairs is highly correlated so that there is a resultant orbital angular momentum describing the liquid as a whole, which might therefore be regarded as an orbital ferromagnet, and many of whose properties would clearly vary depending on the direction in which they were measured. An anisotropic superfluid of this sort is an object previously unknown in nature.

Much theoretical discussion has centred on the way in which the spins and orbital angular momenta are correlated with each other, but it now seems fairly well agreed that in the A phase the Cooper pairs each have a resultant orbital angular momentum of magnitude $1h$, and that the spin and orbital moments for each pair lie at an angle to each other. Leggett, in his 1973 paper, considered various states of this type and predicted the magnetic properties which might be observed for each. In particular, he showed that for one possible state, the so called axial state, there should be a longitudinal NMR absorbtion, in addition to the usual transverse one, whose frequency $\omega_0(T)$ was independent of magnetic field and which was connected by the simple relation $\omega^2=\omega_L^2+\omega_0^2(T)$ to the shift with temperature of the transverse NMR signal of frequency ω.

Members of the Cornell group have now carried out the experiment suggested by Leggett. They have been able to determine $\omega_0(T)$, first, by observing directly the predicted longitudinal resonance and, second, by measuring the shift with temperature of the transverse resonance. Values of $\omega_0(T)$ derived in these two different ways were indeed found to be in good agreement with each other, except very close to the upper transition temperature. Many features of the data require further investigation, notably the change with temperature of the linewidth of the longitudinal resonance, but the Cornell experiment does appear to have demonstrated unambiguously that the A phase of superfluid ^{3}He is in the axial state described by Leggett.

Hexosaminidase and Tay-Sachs disease

from a Correspondent

ONE of the two main electrophoretically distinguishable N-acetyl hexosaminidases (hexosaminidase A) is deficient in tissues of patients with Tay-Sachs disease, a fatal inherited disorder of infants in which the complex lipid, ganglioside GM_2 accumulates excessively in the brain. Hydrolysis of the terminal N-acetyl galactosamine from GM_2 is presumably normally catalysed by hexosaminidase A but not hexosaminidase B. Several important questions still remain to be answered, however, concerning the nature of the relation of the enzymes to each other and also the low activity reported (Sandhoff and Wässle, *Hoppe-Seyler's Z. physiol. Chem.*, **352,** 1119; 1971) of purified hexosaminidase A towards GM_2.

That a genetic relationship exists between A and B was indicated by the discovery that in some patients both the A and B enzymes are deficient (Sandhoff's disease). The enzymes also resemble each closely—in particular they have the same molecular size, and antisera raised to either enzyme will cross react with the other form. Two main hypotheses have been seriously considered, one being that A is formed from B by an enzymatic conversion which affects a non-protein portion of the molecule (the converting enzyme being deficient in Tay-Sachs disease) and the other that the enzymes are both multimeric being made up of similar and dissimilar subunits.

These problems have been discussed again recently in several papers and some interesting new evidence has been presented (Srivastava *et al.*, *J. biol. Chem.*, **249,** 2043; 1974; Srivastava *et al. ibid.*, 2049; Srivastava and Beutler, *ibid.*, 2054; Lalley *et al.*, *Proc. natn. Acad. Sci. U.S.A.*, **71,** 1569; 1974; Li *et al.*, *J. biol. Chem.*, **248,** 7512; 1973). Srivastava, Beutler and colleagues have purified the N-acetyl hexosaminidases of human placenta to homogeneity. They claim that the amino acid compositions of the two enzymes are different. The molecules were found to be multimeric by SDS (sodium dodecyl sulphate) electrophoresis (and if they are right they are hexamers). Immunological studies have demonstrated that a specific anti-A antibody can be formed in addition to the non-specific cross reacting anti A/anti B. Patients with Tay-Sachs disease possessed no A antigens whereas one of the two 'Sandhoff' patients had antigenically detectable A and B proteins, and the other patient had the A protein only. The authors conclude that the A and B enzymes possess subunits in common (β) and that at least A must have specific subunits (α) determined by a separate locus such that A is $(\alpha\beta)_n$ and B is $(\beta_2)_n$ or alternatively $(\beta\gamma)_n$ (γ representing a polypeptide subunit determined by a third locus). The defect in Tay-Sachs disease would represent a mutation causing the diminished production of α chains, whereas that in Sandhoff's disease would be a mutation of the β chain (the two patients described probably having different β mutations).

Suggestive evidence for this type of model came from the immunological findings, but the main support came from the amino acid analysis so it will be of particular interest to see whether the amino acid differences (which are certainly not great) can be substantiated.

Evidence which is consistent with the two locus model of Srivastava *et al.* (and also with the conversion model) is presented by Lalley *et al.* from their human–mouse cell hybrid results. As the human chromosomes are shed from hybrid cells the enzymes determined by genes on those chromosomes are also lost. On careful examination of 60 hybrid clones they observed the loss of A and B together, A without B, but never B without A, and concluded that the expression of A requires the presence of the gene coding for B as well as the gene for A expression, and that the two loci are on different chromosomes. They also provide a probable explanation for the conflicting results of another group (van Someren and van Henegouwen, *Humangenetik*, **18,** 171; 1973).

Synthetic substrates have largely been used to characterise the hexosaminidases. Srivastava *et al.* and also Li *et al.* report that much of the original activity

of their tissue extracts towards the presumed *in vivo* substrate GM_2 was lost on purification of hexosaminidase A. Li and colleagues, however, provide exciting new evidence that hexosaminidase A (but not B) activity towards GM_2 can be stimulated by a non-dialysable, non-enzymatic, heat-stable liver 'factor'. How does this finding fit in with the subunit model? Is the factor ever an integral part of the hexosaminidase A molecule? Further purification and characterisation of this component will clearly be informative.

East and West ribosomes

from a Correspondent

A SYMPOSIUM on ribosomes organised at Schloss Reinhardsbrunn from May 13–16 by the Biochemical Society of the German Democratic Republic provided a rare opportunity for scientists from East and West to discuss their work together at first hand. Many of the reports came from the two big ribosome groups in Berlin, with eukaryotes to the East of the Wall and prokaryotes to the West, and the time of the meeting was evenly divided between the two classes of ribosome.

To start with the prokaryotes, H. G. Wittmann summarised the work being done in West Berlin on mutant proteins from both subparticles of *Escherichia coli* and B. Wittmann-Liebold (W. Berlin) described amino acid sequences of many of these proteins; a clear pattern of amino acid changes in mutants of several proteins has emerged. The emphasis in *E. coli* has moved to the 50S particle, and R. Brimacombe (W. Berlin) reported two 50S ribonucleoprotein fragments, one containing proteins known to associate with 5S RNA. From the work of V. Erdmann (W. Berlin), it now clear that 5S RNA is capable of interacting with the TψCG loop of transfer RNA, and D. Richter (W. Berlin) showed further that oligonucleotide TψCG inhibits ribosomal functions associated with the A (aminoacyl tRNA) site, but does not affect the P (peptidyl tRNA) site. I. Rychlik (Prague) described a very specific inhibitor (TPCK) which prevents the formation of a ternary complex between tRNA, GTP and the elongation factor T_u. In other experiments on 50S sites, K. Nierhaus (W. Berlin) rebound single 50S proteins to lithium chloride cores, to identify the proteins involved in peptidyl transferase activity and chloramphenicol binding. A similar approach was used by G. Howard (Basel Institute for Immunology) to look for proteins involved in binding of elongation factor G and the antibiotic thiostreptone.

Affinity labelling is a technique which is being used with great success to pinpoint functional centres on the ribosome. O. Pongs (West Berlin) reported experiments with analogues of chloramphenicol and puromycin, and W. Möller (Leiden) an analogue of GTP. E. Küchler (Vienna) used affinity label analogues of both tRNA and mRNA designed to attach to protein, and also a tRNA analogue which reacted with the 3′ half of 23S RNA. A. Girshovitch (Poustchino) and D. Knorre (Novosibirsk) both preferred to use tRNA analogues which could attach to protein or RNA, and found that the RNA was preferentially attacked.

Coming now to the eukaryotic results, the affinity label method has also been used successfully here by J. Stahl (E. Berlin) to identify two proteins at the 60S A site with a puromycin analogue. H. Welfle (E. Berlin) and P. Westermann (E. Berlin) reported experiments on iodination of rat liver ribosomes. Those of Westermann were particularly interesting, as he was able to show which proteins are specifically protected from iodination by bound mRNA, tRNA and factors. W. Möller (Leiden) found that two acidic proteins from yeast 60S ribosomes could be interchanged with proteins L7/L12 from *E. coli*, with retention of EF activity. The surface of eukaryotic ribosomes is rich in pyrimidines, according to M. Saarma (Tartu) who suggested that these could interact with poly(A) as the first step in mRNA binding.

On the strictly functional side, H. Bielka (E. Berlin) showed that ribosomes from different tissues are very similar in activity, but that the corresponding cytosolic fractions are very variable. The ever-increasing complexity of mammalian initiation was summarised by T. Staehelin (Basel Institute for Immunology); the number of initiation factors now stands at six, and ATP is also involved. H. Bloemendahl (University of Nijmegen) described his calf eye-lens cell-free system, which seems a useful alternative to the reticulocyte system, and a good summary of current knowledge of ribosome-membrane interaction came from G. Blobel (New York). G. Shapira (Paris) talked about his new RNA species which stimulates protein synthesis; it is about half the size of tRNA, and seems not to be interchangeable between different systems.

Finally, the electron microscopists V. Vasiliev (Poustchino), N. Kiselev (Moscow) and G. Lutsch (E. Berlin) were in reasonable agreement that the smaller subparticle of both pro-and eukaryotic ribosomes is divided into two distinct regions of unequal size, but failed to agree on the shape of the large subparticle of eukaryotes.

Protein receptors of juvenile hormone

from our Insect Physiology Correspondent

IT has long been assumed that the lipid soluble juvenile hormone must be transported in the haemolymph in protective association with a hydrophilic carrier which was likely to be a protein. Emmerich and Hartmann (*J. insect Physiol.*, **19**, 1663; 1973) have found that in the haemolymph of adult female *Locusta* there are six distinct lipoprotein fractions and one of these (molecular weight 220,000) binds the juvenile hormone of cecropia. It closely resembles the lipoprotein which binds juvenile hormone in *Hyalophora cecropia* itself (Whitmore and Gilbert (*J. insect Physiol.*, **18**, 1153; 1972)). It seemed a reasonable suggestion that this might in fact be a specific carrier lipoprotein which could have a very important role in the action of the juvenile hormone in preventing its unspecific incorporation into the lipophilic phases of the cells and its rapid breakdown to inactive carboxylic and hydrated products.

But Kramer *et al.*, with Law (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 493; 1974), have now recognised the existence of a somewhat different specific juvenile hormone binding protein in the haemolymph of the hawkmoth caterpillar *Manduca*. The authors point out that the C_{18} juvenile hormone, the chief form in the silkmoth *Hyalophora cecropia*, has considerable solubility in water, yielding a monomeric solution exceeding 10^{-5}M. The binding protein has a molecular weight around 34,000; it has a much higher affinity for the hormone and its analogues than for the products of hydrolysis. Kramer *et al.* found that there is sufficient of this specific protein carrier in the haemolymph and it binds hormone at a sufficiently low dissociation constant, for it to take up virtually all hormone present in normal physiological conditions. They find, indeed, that the juvenile hormone is taken up by lipoprotein only when the binding protein has been saturated.

Besides transport in the haemolymph, the question arises as to whether, in analogy with the action of oestrogens in vertebrates, the juvenile hormone binds to a specific receptor in its target organs. It is well known that the insect epidermis is the chief site of action of the juvenile hormone. Schmialek *et. al.* (*Z. Naturforsch.*, **28C**, 173 and 453; 1973) have obtained new evidence of a receptor protein in the epidermal cells of the *Tenebrio* pupa. Using the juvenile hormone analogue 10, 11-epoxy-6, 7-*trans*-2, 3-*trans*-farnesylpropenylether as the active substance, they found that the target cells will accumulate this against

a concentration gradient and will degrade it far more slowly than non-target organs. The receptor has a molecular weight of 360,000 and seems to be a unique compound. It has a very high affinity for the active substance, a very low affinity for the breakdown products. It contains RNA in association with protein.

Filling the gap with the pin cherry

from Peter D. Moore
Plant Ecology Correspondent

IT is now fairly well established that during the course of succession leading to deciduous forest in temperate climates, the peak in plant species diversity occurs at about 100–200 years (Loucks, *Am. Zool.*, **10**, 17; 1970). Following this the full attainment of dominance by deep shade-casting trees and the establishment of a shade tolerant understorey community lead to the elimination of many light demanding plant species more typical of the seral stages. Natural climax forest, however, has an uneven population age structure and is subject to random perturbations resulting in the opening of the canopy, for example as a consequence of lightning strikes and windblows. A mature, stable forest in equilibrium with its environment possesses fragments of seral vegetation within its clearings, and its species diversity is therefore greater than one might suppose, if an adequate sample area is studied (see Hope Jones, *Br. Birds*, **65**, 291; 1972).

Marks (*Ecol. Monogr.*, **44**, 73; 1974) has made specific studies of these self-healing attributes of climax ecosystems. In particular he has concentrated on the modifications in life cycle, and dormancy and seed dispersal mechanisms associated with those species which recolonise areas laid bare by natural perturbations. In ecosystem terms, a gap represents a suboptimal utilisation of the available resources—for example, light, moisture, nutrients—and the species which are to exploit such a situation must either arrive rapidly by seed, or their dormant seeds already present in the soil must germinate and grow.

In New Hampshire, an important species which fills this role is the pin cherry (*Prunus pensylvanica*). It is not found in mature forest communities, but is restricted to clearings in which the forest has suffered disturbance. If the soil of a disturbed area contains abundant pin cherry seeds in a viable state, then a dense stand with a closed canopy develops within about 3 yr. In this case the climax species, sugar maple (*Acer saccharum*) and beech (*Fagus grandifolia*) grow beneath the canopy and assume dominance after about 25–35 yr. If the original soil density of pin cherry seeds is low, then birch and aspen become established at an early stage by seed coming from outside the system, and the final dominance of sugar maple and beech may be delayed until 80–90 yr have passed.

This buried seed strategy which results in the maintenance of pin cherry populations, demands a fairly high density of viable seeds surviving in the soil of the mature phase of the forest. Marks found densities varying between 300,000 and 500,000 viable seeds per hectare at two such mature forest sites in which pin cherry was rare or absent. Original fruit production by dense pin cherry stands was estimated to be between 2 and 3×10^6 fruits ha^{-1}. Germination is triggered by forest disturbance; in laboratory tests removal of endocarps stimulated germination. The longevity of seeds in soil is difficult to examine experimentally, but was estimated to be about 50 yr. The clearance of forest which had been in mature phase for 80–100 yr resulted in little pin cherry regeneration.

Once established, pin cherry grows and accumulates nutrients more rapidly than the final climax dominants, which accounts for its success during the early stages of forest recovery. As far as ecosystem regrowth is concerned, the nutrient demand of pin cherry results in the conservation of nutrient capital which might otherwise have been lost by leaching.

Stability in climax ecosystems is usually defined in terms of the system's capacity to recover from disruption. Evidently this stability depends ultimately on species, like the pin cherry, which may be totally absent from stands of mature climax dominants, or represented only by seeds lying dormant in the soil.

Polyadenylation in the cytoplasm

from Benjamin Lewin
Molecular Genetics Correspondent

THE purpose of nuclear polyadenylation remains obscure and an addition to this puzzle is now made by the observation of Slater and Slater (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 1103–1107; 1974) that cytoplasmic polyadenylation takes place in sea urchin eggs. It is by now well established that in mammalian cells a sequence of about 200 adenine residues is added to the 3′ end of an heterogeneous nuclear (hn) RNA molecule before cleavage of this region. The poly(A)-containing sequence is then transported to the cytoplasm to serve as messenger RNA. Addition of poly(A) takes place only in the nucleus of mammalian cells; since inhibiting the addition of poly(A) prevents processing of mRNA, it seems reasonable to suppose that poly(A) is implicated in some essential way in the maturation process.

But poly(A) is also present in viral messengers found only in the cytoplasm and in mitochondrial messengers. Speculation that it may therefore also have a direct role in translation seems to have been refuted by research in several laboratories, which has shown that mRNA lacking poly(A) can be translated as efficiently as mRNA containing it. But force to the argument that nevertheless poly(A) must be implicated in some way in the cytoplasmic function of mRNA is now lent by the results that Slater and Slater report.

Fertilisation of sea urchin eggs causes a sudden burst of synthesis of poly(A); the recent experiments of Slater *et al.* (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 406–411; 1973) and Wilt (*ibid.*, 2345–2349) have suggested that this might represent the addition of poly(A) to previously existing messengers, a situation which contrasts with the addition of poly(A) only to newly synthesised nuclear transcripts in mammalian cells. Slater and Slater now report experiments to test this model. By incubating fertilised eggs with both ^{3}H-adenosine and ^{14}C-uridine, they distinguished newly synthesised mRNA (which possesses the ^{14}C label) from mRNA synthesised before fertilisation (which lacks this label). All RNA possessing poly(A) should contain a tritium label; and if this mRNA was synthesised previously the ^{3}H-adenosine should be located exclusively in the poly(A) segment, whereas if these molecules are newly synthesised some labelled adenosine should be present also in the other parts of the messenger.

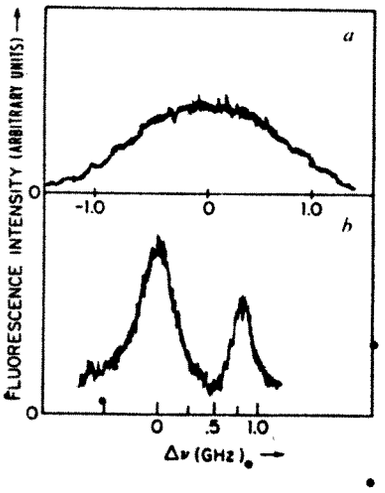
The ^{3}H and ^{14}C labels show a different sedimentation distribution, which implies that they must enter different mRNA species; that is, the poly(A) is not added simply to newly synthesised messengers. The ^{3}H-adenosine which enters the mRNA fraction is found very largely in the poly(A) fraction which can be reclaimed after digestion with ribonuclease; this suggests that only the poly(A) part of the molecule is newly synthesised.

This implies that some mechanism must exist in the cytoplasm for polyadenylating messenger RNA, a conclusion which raises many important questions about the possible role of this polyadenylation. One obvious question is whether the messengers to which poly(A) is added after fertilisation possessed any poly(A) to start with or whether they completely lacked it. If messengers synthesised before fertilisation lack poly(A), then they must be produced by a mechanism in part different from that prevailing when

poly(A) is added at the nuclear stage. Similar questions to those asked about the nuclear addition of poly(A) can be directed to the cytoplasmic addition—are only certain messengers selected for polyadenylation, what happens to messengers which do not receive poly(A), does polyadenylation have some role in controlling translation? No function for poly(A) in the cytoplasm is yet apparent, but with teleological arguments becoming ever more popular in molecular and cell biology, many will be tempted to conclude that some important function of the poly(A) remains to be discovered.

Eliminating Doppler broadening

from a Correspondent



THE spectra of atoms (and molecules) are replete with information some of which is unfortunately inaccessible because the fine structure of spectral lines is often unresolved. Consequently, spectroscopists strive constantly to improve their resolution. The limitations imposed on spectral resolution are not, however, always instrumental but can be inherent in the atomic assembly. For example, atoms of a gas present a whole range of velocities to the direction of propagation of a light source because of their thermal motions. Now if ν_0 is the frequency of radiation required to raise an atom from its (sharp) lower state to a (sharp) upper energy state when it is stationary relative to the source, then an atom receding from the source 'sees' a number of waves per second (that is a frequency) less than ν_0. The receding atom must, of course, absorb radiation which it perceives to have frequency ν_0 and which relative to the stationary source must therefore exceed ν_0. That the Maxwell-Boltzmann distribution of atomic velocities in the source direction ensures a distribution of absorption frequencies even though each atom has sharp energy levels—the so-called Doppler broadening.

Doppler broadening can be overcome if one selects only atoms within a narrow band of velocities relative to the source so that they all absorb at the same frequency. Several velocity selection techniques are used, including atomic beams and laser saturation spectroscopy (see *Nature*, **235**, 127; 1972). A further, elegant method of dealing with Doppler broadening is now described independently by two groups (Biraben, Cagnac and Grynberg, *Phys. Rev. Lett.*, **23**, 643; 1974; Levenson and Bloembergen, *ibid.*, 645).

The essence of the technique used by these authors is very simple. Both groups investigate the normally forbidden 5S←3S electronic transition of the sodium atom by means of two-photon absorption. This transition is, in fact, a closely-spaced doublet (because of coupling of electronic and nuclear spin angular momentum) with separation 784 MHz but its resolution is precluded in the presence of the aforementioned Doppler broadening which confers a half-width of about 1,000 MHz on each component.

Low pressure sodium vapour is subjected to monochromatic radiation from a tunable laser at a frequency equal to one half that of the 5S←3S transition but corresponding to no other known energy state separation within the atom. Those few sodium atoms of thermal velocity such that the 5S←3S level separation is Doppler-shifted into resonance with twice the laser frequency can absorb simultaneously (but with low probability) two photons from the radiation and so raise atoms to the 5S state. As the laser is tuned, a weak Doppler broadened absorption profile (detected by counting photons emitted from the 5S state) is generated as shown in the figure (*a*). When, however, a mirror is positioned so as to reflect the radiation back through the sodium vapour and establish within it a radiation standing wave composed of two oppositely travelling waves, a given atom can absorb two photons by an additional mechanism—one from each of the counter-propagating beams.

It is clear therefore that for any atom the Doppler shift associated with absorption of a photon from one beam is equal and opposite to that associated with absorption from the other beam. The net result is that each and every atom, regardless of its velocity relative to the radiation source, absorbs two photons from the standing wave but only when the laser frequency is exactly one half the 5S←3S level separation. When the laser is tuned through this frequency the doublet character of the transition is resolved (see figure (*b*)), the Doppler broadening having been neatly eliminated.

One expects the weak Doppler broadened signal already mentioned as arising from absorption of two photons from one of the component travelling waves to provide a background pedestal to the observed doublet of figure (*b*), but this has been eliminated by an additional sophistication of the experiment. The two oppositely travelling beams are arranged to be circularly polarised in opposite senses. A rigorous selection rule governing transitions between atomic electron states precludes the 5S←3S transition if both photons are absorbed from a single beam of radiation circularly polarised in only one sense but not if one photon is absorbed from each of two beams of opposite circular polarisation. The weak Doppler broadened pedestal is therefore excluded while the sharp doublet remains.

Little evidence for Palaeozoic arthropod and plant interaction

from Barry Cox
Vertebrate Palaeontology Correspondent

ON April 30, the Palaeobotanical Group of the Linnean Society of London organised a symposium on the interrelationships of Palaeozoic terrestrial arthropods and plants, which took place at the society's rooms in Burlington House. Several contributions set the Palaeozoic scene. M. A. Calver (University of Leeds) discussed the depositional environment of the British Coal Measures. He showed the gradually decreasing frequency of the marine incursions into this low-lying area of coastal swamps, and briefly reviewed the two conflicting theories of the deposition of coal. R. H. Wagner (University of Sheffield) described the distribution of the Upper Carboniferous flora of the world. He contrasted the rich equatorial flora of Euramerica with the poorer and more conservative Gondwana flora, and showed that there were some indications of different swampland, dryland and upland floras.

Turning to the vertebrates, A. L. Panchen (University of Newcastle upon Tyne) described the ecology and distribution of Carboniferous tetrapods, and suggested that the tetrapods might have evolved in Euramerica. Though herbivorous reptiles probably evolved in the Upper Carboniferous, their remains are rare until the Lower Permian.

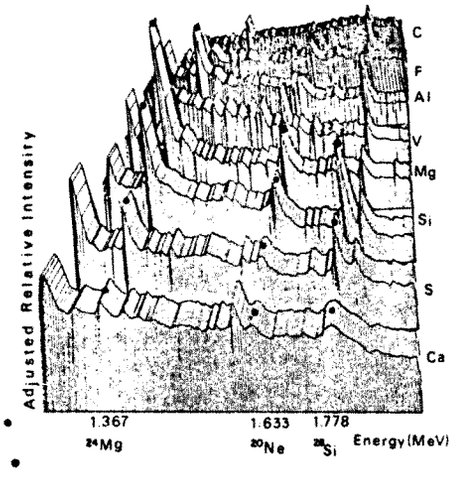
The general evolutionary background of the arthropod radiation was described by S. M. Manton (Queen Mary College, London). W. D. I. Rolfe (University of Glasgow) dealt with the

non-insectan arthropods of the Palaeozoic. The most spectacular of these were the 6-foot long arthropleurids of the Carboniferous of Euramerica, which seem to have lived within the leaf litter, splitting it apart with their flattened heads and bodies—and their gut contents suggest that they fed on lycopod material. The Palaeozoic mites seem to be related to living forms which feed on fungi.

The biology of Upper Palaeozoic insects was discussed by R. J. Wootton (University of Exeter). Insects were almost unknown before the Upper Carboniferous and, even then, knowledge of them is almost exclusively limited to the Euramerica coal swamp fauna. The modern herbivorous groups of insect were almost unknown in the Palaeozoic and holometaboly, which enables totally different adaptations of larva and adult, did not appear until the Permian. Such forms as *Stenodictya* may have been a sap sucker or have picked up spores from sporangia.

Finally, two contributors dealt specifically with the theme of this symposium. W. G. Chaloner (Birkbeck College, London) produced some possible (if contentious) examples of possible plant-animal interaction. These included some plants from the Rhynie Chert which appear to have been damaged during life, and the strong coats of some Devonian spores which may have been adjusted to resist chewing or digestion. P. D. W. Barnard (University of Reading) categorised the ways in which animals could have used plants as food, and the types of evidence of this activity that might have survived. The instances that he had been able to gather together, however, were few. Plumstead has described leaves of *Glossopteris* with ragged edges which could well have been caused by browsing arthropods. Holes in the seeds of *Samaropsis* have been described by Sharon, and Barnard himself has described holes in the nut-like megaspore of *Trigonocarpus*; both of these could well have been due to attack by insects. Finally, some coprolites contain spores, and a specimen of the reptile *Protorosaurus* contains conifer seeds in its abdominal region.

Despite Barnard's best efforts, one's prevailing impression of the symposium was of a production of Hamlet in which the Prince made only fleeting appearances, and indeed there seems little chance of any great variety of unequivocal evidence of the interaction between Palaeozoic plants and arthropods. The meeting also served to demonstrate what a high proportion of knowledge of Carboniferous life is derived from one single (and possibly unusual) environment—the swamplands of Euramerica.



Why do pions eject 'alpha particles' from nuclei?

from Peter E. Hodgson
Nuclear Theory Correspondent

SEVERAL recent investigations have shown that when slow pions or kaons are captured by nuclei, the particles emitted promptly are very often such that the residual nucleus is an excited state of the target less one, two or more α particles or the equivalent numbers of neutrons and protons. The most plausible explanation is that somehow the pions or kaons eject α particles but this has not yet been established because the residual nucleus is identified only by the γ rays it emits, and the particles emitted previously are not detected.

A further important result has been obtained by V. G. Lind and colleagues working in the United States (*Phys. Rev. Lett.*, **32**, 479; 1974), who looked at the results of interactions of fast negative pions (220 MeV) with a range of light nuclei from carbon to vanadium. It is very difficult to detect directly the particles emitted from these intersections so, as in the previous work, the prompt γ rays were studied instead. These are emitted immediately after the particles resulting from the initial interaction. Some of the γ-ray spectra are shown in the figure, and it is notable that there are several peaks common to the spectra from different nuclei.

The energies of these γ rays identify the nucleus from which they were emitted, and it is then found that in the case of even–even targets the most likely residual nuclei correspond to removing one, two or several α particles (or the equivalent numbers of nucleons) from the target. In the case of the odd-A nuclei the γ rays correspond to the removal of a triton or an α particle or a triton plus an α particle from the target nucleus. The cross sections for these processes are comparable to the inelastic scattering cross sections. It is found that the proportion of multiple emissions of α particles compared with single emissions increases with nuclear size.

Some of the prompt γ-ray spectra emitted after interaction of 220 MeV negative pions with a range of nuclei. The lines marked with a solid dot appear in many spectra and correspond to the multiple removal of α particles.

The experimental technique does not distinguish between the emission of an α particle and the emission of two neutrons and two protons, since only the residual nucleus is identified. The relative likelihood of the two processes, and indeed of all possible processes and hence residual nuclei, can be calculated from statistical theory. It is found that this gives results completely different from those found experimentally so that multiple 'α' emission cannot be explained by the statistical theory.

These results have now been confirmed by studies of the interactions of both positive and negative pions with ^{27}Al and ^{28}Si by Ashery and colleagues (*Phys. Rev. Lett.*, **32**, 943; 1974) from Tel Aviv. The negative pions had an energy of 70 MeV and the positive pions energies of 25, 70 and 100 MeV.

Using essentially the same method as the United States group, they also found that there is a large cross section for removing an 'α particle' and leaving the nucleus in its first excited state. This occurs even below 25 MeV, which is the threshold for the emission of two protons and two neutrons, and this strongly supports the hypothesis of cluster emission.

It is found that at 70 MeV the cross section for 'α' emission is very similar to that for the elastic scattering of pions by free α particles, thus suggesting that the pions are simply knocking out pre-existing α particles from the target nuclei. Substantial cross sections are also found for reactions corresponding to the emission of deuteron clusters.

These experiments on the interaction of fast pions with nuclei thus give results similar to those found in studies of the interaction of slow pions or kaons. There seems to be some process that takes place in the initial stages of the interaction that leads to the preferential emission of α particles. This in turn suggests that there are α particles in the nuclear surface, a hypothesis for which there is already much evidence.

It is important to continue this work, and in particular to try to detect and identify directly the particles emitted in the early stages of the interaction. This is a difficult experimental problem but if it can be solved it will shed new light on the problem of α particles on the nuclear surface.

Origin of kimberlite pipes by diapiric upwelling in the upper mantle

H. W. Green II
Department of Geology, University of California, Davis, California 95616

Y. Gueguen
Laboratoire de Géologie Structurale, Nantes, France

A diapiric mechanism is presented to explain geochemical data on the thermal structure of the upper mantle. It is emphasised that any model to fit the data cannot be a steady state model, and it is concluded that the data are inconsistent with the popular interpretation of the seismic low velocity zone as a partially melted region.

THE 'pyroxene geotherm' technique[1-3] utilises the experimentally determined partitioning of calcium[4] and aluminium[2] between coexisting clino and orthopyroxenes in order to determine the conditions of origin of garnet and spinel peridotites. Application of the technique to xenoliths from kimberlite pipes shows that: (1) the xenoliths are fragments of the upper mantle accidentally included in the kimberlite during its passage to the surface; (2) the xenoliths from each pipe describe a 'palaeogeotherm' which abruptly steepens at depths between 140 and 200 km (Fig. 1); (3) the point of inflection in each geotherm corresponds to chemical[5] and textural[6-8] changes. The shallower, 'normal' portion of the geotherm is characterised by coarsely crystalline harzburgites which have no significant preferred orientation and are strongly depleted in basaltic constituents; the steepened, deeper portion is represented by highly deformed, extensively recrystallised lherzolites capable of producing normal basalts by partial melting[9]. It has been pointed out[1,8,10] that the shape of the palaeogeotherms is unlikely to reflect a steady state situation and it has been proposed that the steepening results from shear heating which occurred in the seismic high attenuation, low velocity zone (HALVZ) during the breakup of Gondwanaland. We agree that the assumptions necessary for any steady state model are unreasonable but we question that the shear-heating model quantitatively satisfies the data. This article presents an alternative diapiric model, postulating upwelling from within or below the HALVZ.

The model

We assume that a small density inversion of unknown origin initiates upwelling at a depth of more than 200 km. The upwelling will be self perpetuating if the temperature gradient exceeds that for adiabatic expansion, a well known property of modern models of the thermal structure of the upper mantle[11]. The upwelling therefore becomes a diapir which very soon reaches a quasi-steady limit velocity. It is driven principally by the buoyancy force which results from the temperature difference between the interior of the diapir and the surrounding, undisturbed mantle. If the velocity of ascent is rapid compared with the rate of heat loss, the diapir may reach the solidus and partially melt. We assume that such melting occurs just below the point of the deepest xenoliths and that the kimberlitic magma is produced. The magma brings up fragments both from the top of the diapir, and from above it.

For quantitative comparison of this model with the geochemical data, the geothermal gradient along the axis of the diapir can be calculated (Fig. 2). The heat flow equation must therefore be solved. Neglecting heat sources[12]:

$$\rho c_p \left(\partial T/\partial t + v_i \nabla_i T\right) = K\nabla^2 T + (\eta/2)\left(\partial v_i/\partial x_k + \partial v_k/\partial x_i\right)^2 \quad (1)$$

where ρ is the density, c_p the heat capacity at constant pressure, T is temperature, t is time, v_i is the velocity of the moving rocks, K is the thermal conductivity and η the viscosity. The second, third and fourth terms are the contributions of convection, conduction, and viscous heating respectively. The well known difficulty in obtaining an analytical solution to equation (1) leads to a comparison of the contributions of the various terms thus simplifying the problem but remaining within the accuracy of the data. The relative importance of the convection and viscous heating terms is of paramount importance to the form of our solution. We assume that the spatial variation of velocity within the diapir can be satisfactorily approximated by a single average velocity $< v_3 >$. We also assume that the average temperature gradient $< \frac{\partial T}{\partial x_3} >$ is of the order of 1° C km^{-1}; $c_p = 10^7$ erg $^\circ$ C^{-1} g^{-1}; $\rho = 3$ g cm^{-3}, $\eta = 10^{21}$ poise and that $< \frac{\partial v_i}{\partial x_i} > = \frac{< v_3 >}{R}$ where R, the radius of the diapir, is 50 km. For this comparison, we calculate the average velocity by equating the driving force to the viscous drag on the diapir considered as a whole, and using an average temperature

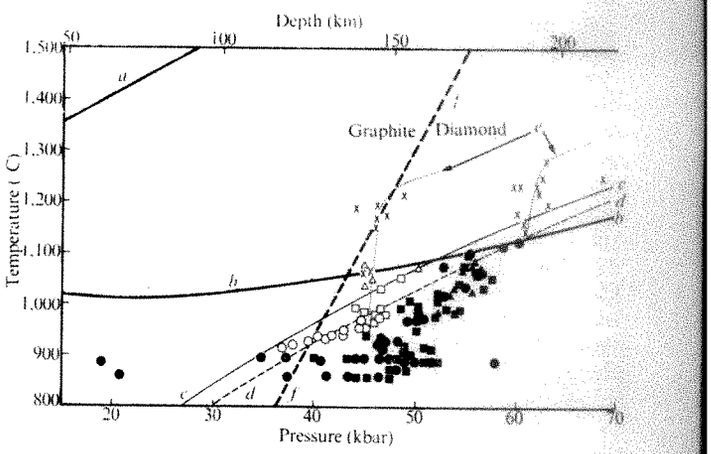


Fig. 1 Thermal and textural structure of the upper mantle beneath southern Africa at the time of emplacement of Cretaceous kimberlite pipes. Data and phase boundaries after Macgregor[3]: *a*, dry peridotite solidus; *b*, vapour saturated solidus (H_2O:CO_2 = 1:3); *c*, C and R shield geotherm; *d*, model geotherm (undisturbed); *e*, model geotherm (perturbed); *f*, graphite–diamond phase boundary. Open symbols, South West Africa region; closed symbols, Kimberley region; circles, coarse grained, undeformed xenoliths with coarse granular textures; squares, coarse grained, undeformed xenoliths with coarse tabular textures; triangles, plastically deformed xenoliths with porphyroclastic textures; crosses, plastically deformed xenoliths with mosaic textures. Shield geotherm of Clark and Ringwood[11] (*c*) given for comparison

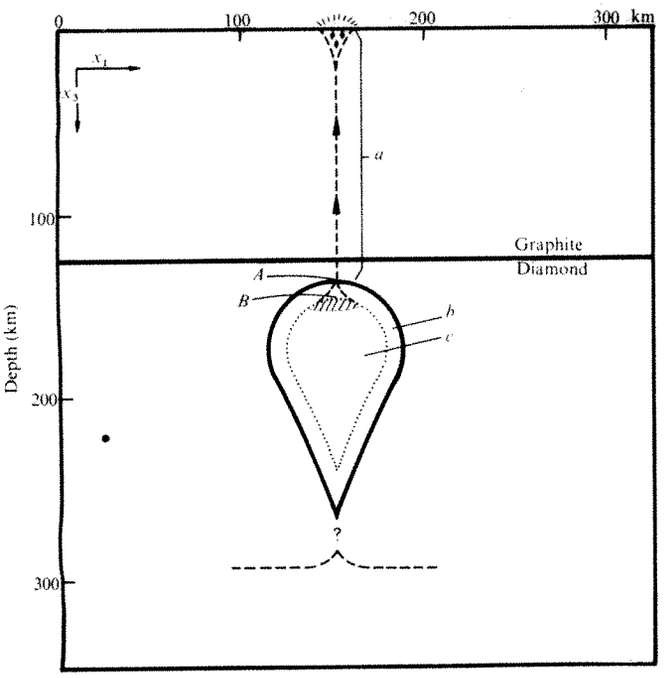

Fig. 2 Idealised drawing of a rising diapir at the time of melting and kimberlite formation. Region *a*, undisturbed lithosphere; region *b*, outer 'rind' of diapir affected by conductive cooling during upwelling; region *c*, interior of diapir cooled only by adiabatic expansion. Points *A* and *B* mark transitions from one region to another. Shaded area diagrammatically indicates melting at the top of region *c*.

difference of 100° C between diapir and surrounding rocks. The result, which is almost independent of the shape of the diapir[12], is $< v_3 > = 1$ cm yr^{-1}. Then:

$$\frac{\rho c_p < v_3 > < \partial T/\partial x_3 >}{(\eta/2)(< \partial v_3/\partial x_1 >)^2} \simeq 500 \qquad (2)$$

Even for these conservative assumptions, the convection term is dominant by more than two orders of magnitude. The likelihood that η is less than 10^{21} poise further reduces the importance of viscous heating, and therefore the shear heating term cannot have a controlling effect on our model.

A one-dimensional model can be used if the diapir is sufficiently large for heat loss at the sides not to affect appreciably the central axis. For the times relevant to the model, the heat diffusion distance[12] is less than 20 km, so that any diapir large enough not to be affected by shear heating (that is, $R \geqslant 25$ km) can also be treated as a one-dimensional problem; the side effects are unimportant in a first-order approximation. Finally, we assume that heat lost through the top of the diapir is carried away by the mantle flowing around the advancing mass. We thus obtain the model shown in Fig. 2. The calculated axial geotherm will have three parts: (*a*) an undisturbed geotherm above the diapir; (*b*) the top of the diapir affected by diffusive loss of heat; (*c*) the tail of the diapir, characterised by the adiabatic gradient. The simplified model matches parts *a* and *c* by a temperature perturbation (*b*) on the model geotherm, which is chosen as a good fit to the geochemical data between 100 and 200 km depth and fitted to the shield geotherm of Clark and Ringwood[11] at lesser and greater depths (Figs 1 and 3).

The perturbation obeys the heat flow equation:

$$\partial T/\partial t = (K/\rho c_p)(\partial^2 T/\partial x_3^2) \qquad (3)$$

The boundary condition at the top of the diapir is $T_0(t) = v_3 (\partial T/\partial x_3)_0 t$ where t is the time elapsed since the formation of the diapir, $K = 4 \times 10^4$ erg cm^{-1} s^{-1} ° C^{-1} (10^{-3} calorie cm^{-1} s^{-1} ° C^{-1}) and the other values are as already given. The boundary condition equates the temperature at the top of the diapir with that just above it in the undisturbed mantle; it is the expression of the heat flowing out at the top of the diapir. Between 250 km and 400 km depth, $(\partial T/\partial x_3)$ is relatively constant and for the calculations we have adopted 1.7 ° C km^{-1}. In this simplified form the problem has the analytical solution[13]:

$$T(x_3,t) = 4 < v_3 > (\partial T/\partial x_3)_0 \, t \, i^2 \operatorname{erf} [x_3 (Kt/\rho c_p)^{-\frac{1}{2}}] \qquad (4)$$

The calculations have been made for the shallowest and deepest data sets of Macgregor[3], representing the regions of South West Africa (Louwrencia pipe) and Kimberley (grouped data representing the Wesselton, Roberts Victor, Bulfontein and Jagersfontein pipes) respectively. We have chosen to model the undisturbed mantle with a single, representative geotherm because of the uncertainties in the data, the mixed origin of the Kimberley data, and the small effect separate geotherms would have on our results. The chosen geotherm also fits satisfactorily with the data from the Lesotho region[1,3]. The data allow the independent calculation of the time intervals of upwelling, the diapir velocities and then the depths of origin (Table 1, Fig. 1). The calculated depths of origin of the diapirs are surprisingly similar and perhaps represent the depth of the lowest portion of the HALVZ.

Discussion

The diapir model fits the geochemical data well and the adjustable parameters in the model are all chosen to be very reasonable values. Similarly, the calculated times and velocities are reasonable. The production of the kimberlite magma containing xenoliths is a natural consequence of the model, for once initiated, the diapir will rise until it reaches the surface without melting (becoming an alpine peridotite[14]) or it will partially melt and result in the production of kimberlite pipes. We assume that melting occurs at temperatures just above the hottest temperatures indicated by the analysed xenoliths. These temperatures always fall between the dry and water-saturated peridotite solidi[15,16], and the presence of small quantities of water is thus mandatory for the model. The amount cannot be precisely estimated because it is critically dependent on

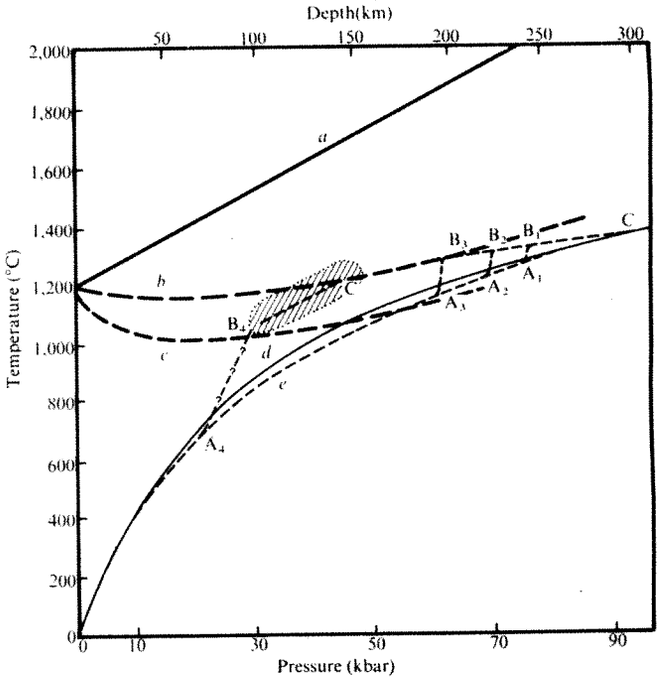

Fig 3 Thermal evolution of the rising diapir in the Kimberley region. *a*, Dry peridotite solidus; *b*, model solidus; *c*, wet solidus (H_2O:CO_2 = 1:3); *d*, C and R shield geotherm; *e*, model geotherm (undisturbed). Point *C* represents origin of the diapir on the undisturbed geotherm. Points A_i and B_i represent successive positions of points *A* and *B* of Fig. 2; *B* moves down the adiabat and *A* down the geotherm. Melting occurs at B_3. Shaded region encompasses data of 'second geotherm' of Macgregor[3]. A_4–B_4–*C'* represents possible earlier diapir responsible for these data.

Table 1 Duration of upwelling, velocity of ascent, and depth of origin of diapirs

Region	Mean velocity	Duration of upwelling	Original depth
South West Africa	5 cm yr^{-1}	3 Myr	290 km
Kimberley	3 cm yr^{-1}	3 Myr	280 km

collection and analysis of xenoliths which equilibrated on the solidus as well as on the accuracy of the pyroxene geotherm. Macgregor[3] points out that 'primary phlogopite' is present in region *a* (Fig. 2) of our model. Texturally this 'primary phlogopite' usually seems to be a replacement phase rather than part of the original paragenesis (Green, H. W. II, and Boullier, A. M., not yet published), but its coarse grain size and apparent stability with respect to the other phases of the rocks strongly indicates an origin which predates incorporation into the kimberlite magma. Thus the rocks do contain small quantities of water.

We have not yet considered the chemical and textural differences present in the xenoliths. The coarse grained harzburgites correspond to region *a* (Fig. 2) and the highly deformed lherzolites exist in region *b* (Fig. 1). We expect such an abrupt textural and chemical transition because the undepleted diapir flows plastically on its margins as it rises through the previously depleted, annealed upper mantle. The top of the diapir would be expected to be the only place where undepleted mantle could be sampled because only this region has lost enough heat to miss the solidus and stay intact.

Macgregor[3] has described a second group of xenoliths in the Kimberley region (Fig. 3). This atypical group plots at distinctly higher temperatures than the first, 'normal', group which is remarkably similar from pipe to pipe and from region to region. If there are two geotherms in the same region then there cannot be a steady-state situation. The second geotherm could represent the 'tail' of an earlier diapir which continued to rise at a reduced velocity after it had been partially melted. Alternatively, the second geotherm could represent an earlier diapir which rose more slowly and consequently never reached the melting point (for example, a velocity of ~ 0.1 cm yr^{-1} would produce the observed slope with our model). In either case the first diapir must precede the second diapir, which brings the fragments to the surface, by only a few tens of millions of years otherwise the internal temperature of the first diapir would be reduced to the normal, unperturbed geotherm. An interesting difference between these two possible explanations is that for the former possibility the older diapir 'tail' could be mineralogically and texturally indistinguishable from normal lithosphere of region *a* (Fig. 2) but in the latter case the first diapir should be chemically undepleted even though it might be texturally similar to normal lithosphere. Unfortunately, the data[3] are not separated in such a way as to allow these possibilities to be tested.

The discovery[3] of the 'second geotherm' in the Kimberley region emphasises the need for a time-dependent explanation for the geo chemical data, but it is not the only observation which supports this class of model. To make a steady state model fit the inflection in the palaeogeotherms a large and discontinuous change in thermal conductivity is required[1,3]. Variation in the depth of the inflection point and its correlation with the xenolith textural types indicate that the effect would have to be produced by the preferred orientation in the deformed rocks or by some inherent effect of deformation on thermal conductivity. Because of the rather weak preferred orientations in these rocks (A. M. Boullier, personal communication) an anisotropy of K of more than a factor of 50 would be necessary. Similarly, any effect of crystal defects on the thermal conductivity would seem to be small because such an effect depends on high concentrations of defects[17], whereas the high temperature deformation undergone by these rocks produces recrystallised grains with extremely low defect densities (Green, H. W. II, and Boullier, A. M., not yet published).

In an earlier model[1,5,8] shear heating in the low velocity zone is proposed to explain the steepened portion of the geotherms. Our calculations show that rates of strain exceeding 10^{-11} s^{-1} would be required to fit the data quantitatively, even assuming that there is no loss of heat by conduction. We consider such rates to be geologically unreasonable and therefore believe that the heat is better provided by a convective mechanism. Our diapiric model is the extreme case in which all of the heat is produced by convection. Other models can be constructed in which both upwelling and shear heating are involved[18], but they are more complicated and therefore more difficult to apply quantitatively.

Two additional consequences of the diapiric model are of considerable interest for understanding upper mantle processes. First, if the model is to be valid, the HALVZ cannot be partially melted; either another fluid[19] or a completely different mechanism[20] must be sought to explain the seismic data. (Interestingly, the same conclusion seems to be required for any model which equates the deformed xenoliths with the HALVZ because these rocks are unmodified and contain no distributed melt phase (Green, H. W., and Boullier, A. M., not yet published).) Second, if xenolith-bearing basaltic eruptions in tectonic and oceanic areas are also preceded by diapiric upwellings, as seems probable to us, then the flow mechanisms evident in the xenoliths reflect the mechanisms of diapirism which may not be the same as those of flow in the asthenosphere. Thus, the conclusions[21,22] that flow in the upper mantle is dominated by movement of dislocations which are climb-controlled does not necessarily apply to asthenospheric flow. These arguments do not, however, contravene those based on post-glacial uplift data and power-law creep in experiments[23].

We thank A. M. Boullier and A. Nicolas for discussion. I. D. Mcgregor kindly permitted use of his data in advance of publication. F. R. Boyd and D. McKenzie provided helpful criticism of the manuscript. H.W.G. thanks the National Science Foundation and the Centre National de la Recherche Scientifique.

Neural antigens of morphologically differentiated neuroblastoma cells

Richard Akeson* & Harvey Herschman*†

*†Brain Research Institute, †Department of Biological Chemistry and †Laboratory of Nuclear Medicine, UCLA School of Medicine, Los Angeles, California 90024

Murine neuroblastoma cells in serum-free medium undergo correlative morphological and serological differentiation. The antigens specific to the differentiated cells are found in large quantities in mouse brain.

MURINE neuroblastoma cells can be induced to differentiate morphologically so as to resemble mature neurones if they are maintained in medium without serum[1]. This morphological differentiation is often not accompanied by biochemical differentiation, as studies of neurotransmitter biosynthetic enzymes[2], glycosphingolipid composition[3], tryptic glycopeptides[4], mouse alloantigens[5] and acrylamide gel patterns of solubilised membranes[6] have shown. Similarly, studies of the development of the ability to generate an action potential and of sensitivity to electrical and chemical stimulation, have produced no consensus on any correlation with morphological differentiation[7–10].

We have described a set of cell surface antigens on morphologically differentiated cells derived from clone N18 neuroblastoma[11]. They are also present in large quantities in particulate preparations of mouse brain, but not in spleen, liver or kidney. Their appearance is the only reported specific change in the cell membranes that correlates with the morphological differentiation of cultured neuroblastoma cells.

We report here that: (1) serological differentiation of N18 neuroblastoma cells correlates with the extension of processes in serum-free medium and (2) direct binding experiments with ^{125}I-labelled immunoglobulin confirm and partially quantify the presence of neurone-specific antigens found only on morphologically differentiated neuroblastoma cells.

Antisera specific to differentiated clone N18 murine neuroblastoma cells were produced by immunisation and adsorption as before[11]. The increased binding of antibodies (at saturating concentrations) to N18 cells maintained for 5 d in serum-free medium (N18-SF) compared with the binding to N18 cells grown in suspension culture on bacteriological plates[6] (N18-sus) implies that new antigens were present on the morphologically differentiated N18-SF cells (Fig. 1). Binding of ^{125}I-immunoglobulin to morphologically differentiated neuroblastoma cells, undifferentiated cells and mouse tissue correlated well with their antigenic activities measured by indirect immunofluorescence and complement fixation[11].

To examine the relationship between process formation and the presence of new antigens on neuroblastoma cells in serum-free medium we used the C1300 neuroblastoma clone 10D (ref. 11), which does not extend processes in serum-free medium. The serological reactivity of 10D cells grown with serum was indistinguishable from that of N18-sus cells measured by complement fixation, immunofluorescence or saturation binding (ref. 11 and Table 1). In addition, 10D cells maintained in serum-free medium for 5 d (10D-SF) neither extended processes nor bound more immunoglobulin than did N18-sus or 10D cells grown in complete medium (Table 1). The presence of new antigens on N18-SF cells was thus related to the formation of processes, and not to an effect of maintenance in serum-free medium.

Morphology and antigenicity studies

We next examined the serological reactivity and morphology of N18 cells maintained without serum for less than 5 d in an attempt to relate antigenicity and morphology. Morphological development increased steadily for 5 d. After 6 d the cultures tended to degenerate. Complement fixing ability (Fig. 2) of N18 cells in serum-free medium decreased initially for 2 d, probably because the cells were derived from near-confluent monolayers, and then increased for 3 d. Confluent cells were to some degree morphologically differentiated, thus a period in nonconfluent conditions may have been necessary for the antigens associated with this differentiation to be removed from the cell surface. Near-confluent cultures grown in complete medium had reactivity similar in both complement fixation and saturation binding assays to that of cells cultured for 3 d without serum. There was thus little serological differentiation during the first 2 d in serum-free medium, followed by a steady increase in antigenic reactivity.

Table 1 Antibody binding to neuroblastoma cells

Antigen	Immunoglobulin bound at saturation (ng)	% of N18-SF Value
N18-SF	48	100
N18-sus	37	78
10D	36	75
10D-SF	35	72

Values are the average from three experiments.

In general the primary morphological change that correlates with increasing immunological reactivity is the formation of steadily lengthening processes on the cells. Morphological development seems to precede antigenic development. The multispecificity of our antiserum is undoubtedly an important source of difficulty in attempting to correlate

discrete antigenic and morphological events.

We next examined the relationship of the new antigens to the antigens of various mouse organs. Our antisera were produced to N18-SF cells, and so the reactive antigens present on the other cells and tissues tested should have been subsets of those found on N18-SF. No relationship between (for example) the antigens present on brain and liver can however, be inferred from Fig. 1. The liver antigens, in whole or in part, could be a subset of the brain antigens, or the two sets of antigens could be independent. To determine the relationship(s) between them, we performed binding experiments using ^{125}I-immunoglobulin adsorbed with particulate material (PM) from various mouse organs. Liver was chosen as a non-neural source of antigen because it binds relatively large amounts of the immunoglobulin (compared with other non-neural tissues) and has low levels of innervation.

Adsorption of immunoglobulin with particulate preparations from liver removed antibodies that bind not only to liver but also to all the other organs and cells tested (Table 2). Antibodies that bind to spleen and heart were removed when the immunoglobulin was adsorbed with liver PM. Therefore the reactive antigens found on these tissues were probably identical to those of liver. In a reciprocal experiment spleen adsorbed all binding activity to heart and liver (data not shown). A small amount of the antibodies that bind to kidney were not removed by adsorption with liver PM. It is not clear whether these antibodies reacted with the neural antigens which were present as a consequence of the innervation of kidney, or with some other antigen not shared by the liver. Binding of liver-PM-adsorbed immunoglobulin to brain, N18-sus and N18-SF cells was reduced by approximately equal amounts. The antigens found on liver seemed to be present on all the cells and organs tested and are probably common to all mouse cells. Immunisation of a xenogeneic animal, the rabbit, would be expected to raise antibodies to species-specific antigens.

As adsorption of the immunoglobulin with brain PM removed all antibodies which bind to other organs (Table 2), brain must contain all the antigens found on the other organs, but not all those present on the cultured neuroblastoma cells. The absolute binding measured in ng to N18-SF cells of brain-adsorbed antibody was reduced more than the binding of such antibody to N18-sus. This reduction suggests the presence of neural antigens found on N18-SF but not on N18-sus. The difference in binding between N18-SF and N18-sus [Δ(SF-sus)] could be reduced 67% by ad-

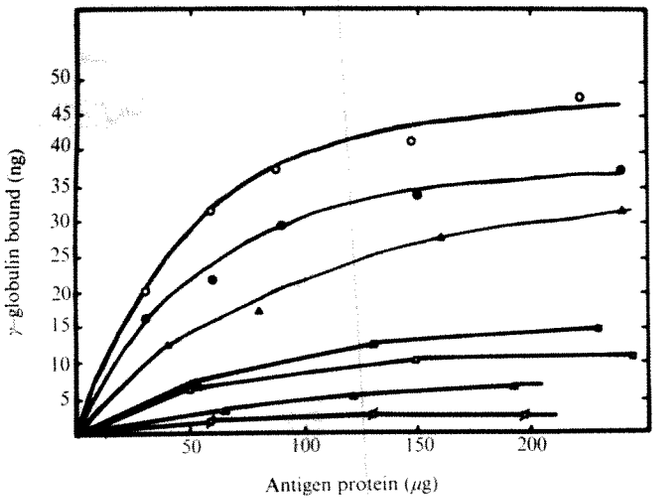

Fig. 1 Binding of ^{125}I-labelled immunoglobulin to mouse organs and cultured neuroblastoma cells. Antisera production and cell culture have been described. All experiments utilised the bleeding from rabbit 147 on the 20th day of the immunisation protocol[11]. Unless otherwise noted, all operations were performed at 0°–8°C. γ-Globulin was isolated by the method of Fahey and Horbettt[14] and labelled by a large scale modification of the method of Greenwood *et al.*[15] using carrier-free ^{125}I (New England Nuclear Corp.). Labelled immunogloblin was separated from unbound iodine on Sephadex G25, diluted with an equal volume of 5 mg ml^{-1} bovine albumin in isotris buffer[16], and stored in aliquots at −20° until use. The specific activity was 0.7 Ci g^{-1}. Cells and organs were prepared as before[11]. Brain samples did not include the olfactory bulb. Spleen samples included only the expressed cells and not the capsule. Whole liver and kidney were used. Heart samples were taken from the caudo-lateral left ventricle wall. There were no substantial differences in saturation binding with tissues from A/J, B_6AF/J, C3H, C57B, HeJ or Swiss Webster mice. Labelled immunoglobulin (260 μg) was shaken for 5 h in a mock adsorption procedure. After filtration, 5 μg was added to each antigen sample. All tissues are from a 60-d-old Swiss Webster mouse. The ^{125}I-immunoglobulin and antigen PM were combined in isotris buffer plus 10% normal rabbit serum (final volume of 1.5 ml) incubated 12-16 h, then centrifuged for 23 min at 45,000*g*. The supernatant was discarded. The pellet was resuspended by vortexing for 15 s in 1.2 ml isotris containing 2 mg ml^{-1} bovine albumin (BA). After a second centrifugation for 26 min at 45,000*g*, the pellet was resuspended in 1.2 ml isotris containing 2.0 mg ml^{-1} BA. The suspensions were then filtered (at room temperature) over a Whatman GF-A glass fibre paper which had been presoaked overnight in 2.5 mg ml^{-1} BA in isotris. The tube was washed twice with 2 ml isotris, and the washes filtered. The filters were rinsed twice with 2 ml absolute ethanol and dried for at least 30 min at 75°C before counting. For each curve the ng of antibody bound by the equivalent amount of HeLa cells is subtracted to obtain the specific binding. This background in the linear portion of the binding curve is 10-15% of the values obtained using N18-SF as the antigen. That the γ-globulin which sticks to HeLa cells is bound nonspecifically is demonstrated by the observations that (a) this binding is a linear nonsaturating function of added HeLa cell protein, (b) exhaustive adsorption of antiserum with an antigen reduces the binding of antiserum to that antigen down to but not below the levels obtained with HeLa cells, and (c) adding excess unlabelled antiserum reduces binding of labelled antiserum to N18-SF down to but not below the level obtained with the same amount of HeLa cell protein. HeLa cells do not react with this antiserum in either complement fixation or immunofluorescence assays. ○, N18-SF; ●, N18-sus; △, brain; ■, kidney; □, liver; ▲, spleen; ⊡, heart.

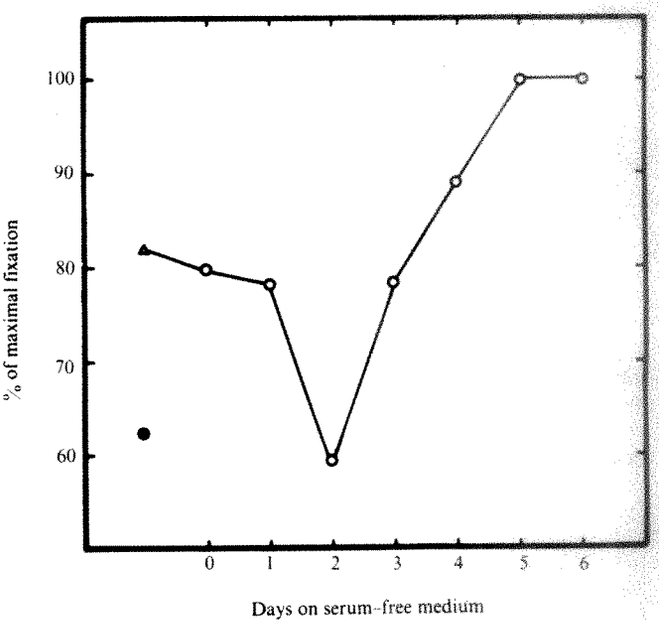

Fig. 2 Complement fixation of N18 cells maintained for varying periods on serum-free medium. Data are expressed as percentages of the maximal fixation obtained with N18 cells maintained 5 d on serum-free medium. Confluent or late log phase cultures were treated with Viokase and plated as before[11] to obtain cultures subsequently maintained in serum-free medium. △, Late log or confluent cultures; ●, N18-sus; ○, N18.

Table 2 Organ adsorption of antibody binding activity

Antigen used for test	% Antibody binding activity adsorbed by: Brain	Liver
N18-SF (differentiated)	75 (32.0)	38 (16.0)
N18-sus	79 (27.2)	51 (17.5)
Brain	88 (22.0)	56 (15.0)
Kidney	95 (14.0)	75 (10.5)
Liver	93 (10.0)	>95 (10.8)
Spleen	>95 (6.2)	92 (5.8)
Heart	>95 (2.5)	>95 (2.5)
Δ(SF-sus)	67 (6.8)	< 5 (0.1)

Two aliquots of 130 μg of ^{125}I-immunoglobulin were adsorbed with 5 mg of liver and brain respectively. This is the amount of antigen necessary to adsorb 90% of the antibodies which bind to brain and about 1.5 times the amount necessary to adsorb 90% of the antibodies which bind to liver. A volume containing 5 μg of adsorbed antibody was added to each antigen sample (150 μg). The mixtures were incubated for 12 h at 8°C. All cells and organs were the same preparations as those described in Fig. 1. Numbers in brackets are ng of antibody binding activity removed.

sorption with brain PM but less than 5% by adsorption with liver PM (Table 2, last line). N18-SF is the only antigen source able to adsorb totally the binding immunoglobulins in the antiserum.

These and other adsorption experiments established the following relationships among the sets of antigens reactive with this antiserum. (1) The set of antigens present on a tissue includes as a subset all reactive antigens of tissues with a lesser total reactivity. For example, the set of reactive antigens present on liver PM includes as subsets those reactive antigens present on spleen and heart PM, while the set of reactive antigens present on brain includes all those of kidney, liver, spleen and heart. (2) Approximately two-thirds of the antigens present only on the morphologically differentiated form of N18-cells are found only on neural tissue. Among antibodies that bind to brain are some that bind to morphologically differentiated but not

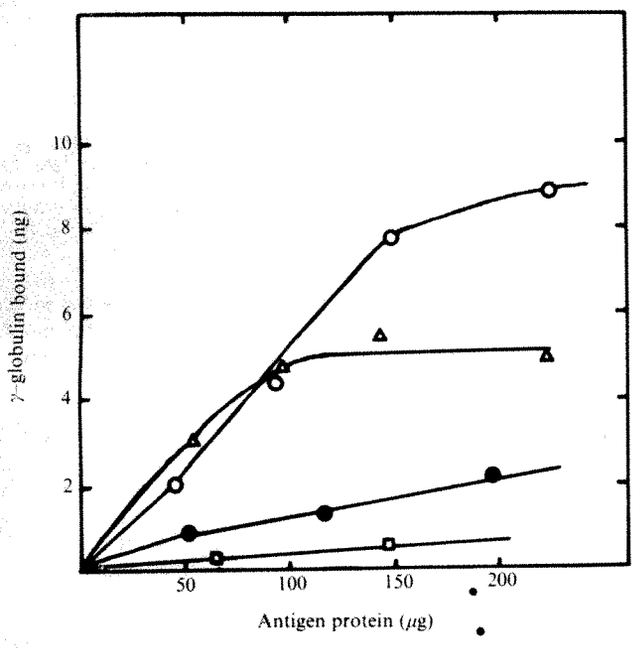

Fig. 3 Binding of ^{125}I-immunoglobulin adsorbed with N18-sus. ^{125}I-immunoglobulin (120 μg) was adsorbed with 3.3 mg of N18-sus PM for 16 h. A volume containing 5 μg was added to each antigen sample and the mixture was incubated 14 h at 8°C. Organs were from a 45-d-old C57BL mouse. Symbols as in Fig. 1.

to undifferentiated neuroblastoma cells.

We attempted to confirm the neuronal specificity of Δ(SF-sus) by further methods. Adsorption of the immunoglobulin with N18-sus removes all antibodies that bind to all cells and tissues tested, except N18-SF and brain (Fig. 3). For such an adsorbed immunoglobulin preparation, Δ(SF-sus) was 6.0 ng, while Δ (brain-sus) was 3.4 ng or 57% of Δ(SF-sus). This value is close to the 67% of Δ(SF-sus) already given (Table 2) as specific to neural tissue. Each of these calculations gives a minimal value because in each

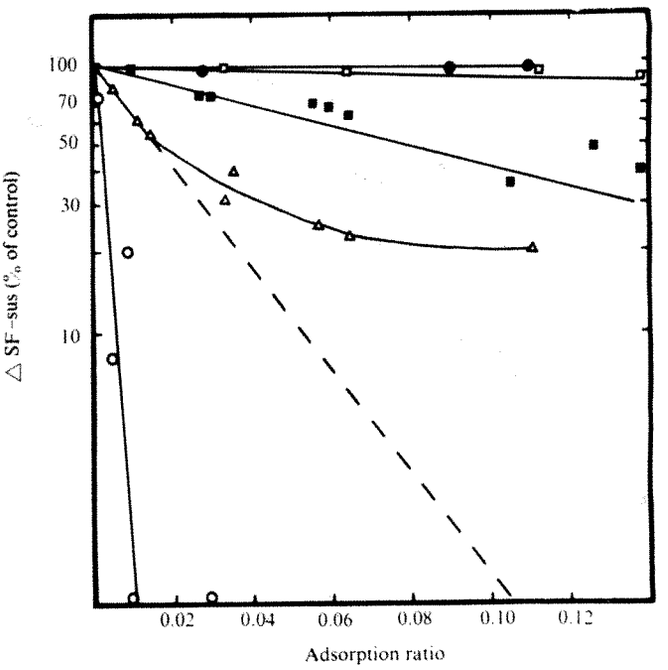

Fig. 4 Exhaustive adsorptions with PM from mouse organs. The reduction in Δ(SF-sus) is plotted as a function of the amount of PM used to adsorb. Spleen cells could not be used in these exhaustive adsorption experiments, due to their affinity for rabbit γ-globulin. This binding is probably due to the presence of receptors for the F_c portion of immunoglobulin molecules[12]. The adsorption ratio is defined as the mg of organ PM per μg ^{125}I-immunoglobulin used in the overnight adsorption. By comparison this ratio in the adsorptions of Table 2 is 0.038. The adsorption ratios at which 90% of the binding activity to each antigen is removed by adsorption with that same antigen are liver, 0.026; brain, 0.038; N18-SF, 0.018. Values for muscle and kidney were not determined. The lines drawn are linear regression fits to the data points in all cases except brain. The dashed line is an extension of the line of best fit to the first three brain adsorption points. The remainder of the solid curve for brain is a free-hand fit of the points. ○, N18-SF; △, brain; ■, kidney; □, liver; ●, skeletal muscle.

case the adsorption of antibody molecules was incomplete. Any unadsorbed binding material was assumed to not be specific to neural tissue.

If adsorption and subsequent direct binding assays were performed with particulate preparations from monolayer 10D-neuroblastoma cells rather than N18-sus cells, the ability of brain to adsorb the remaining (N18-SF specific) immunoglobulin preferentially was unchanged (data not shown). Thus, brain reacted preferentially with an antiserum made specific for the morphologically differentiated state of neuroblastoma cells, whether N18-sus or 10D monolayer PM was used for adsorption. In summary, antigens found only on the differentiated form of N18 neuroblastoma cells were also present on brain but not other organs, when assayed by both direct binding and adsorption.

To determine whether antigens present only on the

morphologically differentiated form of N18 neuroblastoma cells are present in lesser concentrations on particulate material from organs other than brain, we performed binding studies with immunoglobulin exhaustively adsorbed with skeletal muscle, liver and kidney as well as brain PM. The adsorbed immunoglobulins were tested against both N18-SF and N18-sus to determine whether antibodies reactive with antigens unique to the differentiated neuroblastoma cells had been removed.

Liver and skeletal muscle PM did not adsorb significant amounts of the Δ(SF-sus)-specific immunoglobulins (Fig. 4). Adsorptions with brain preparations produced a multiphasic curve. The ratio of the slope of the adsorption curve with N18-SF to that of the initial slope of the brain adsorption curve (dashed line) is 12 : 1, indicating that the specific activity of Δ(SF-sus) antigens was twelve times greater on N18-SF cells than on brain. The slope of the brain adsorption curve seems to be reduced at about 50% reduction of Δ(SF-sus). Therefore the remaining Δ(SF-sus) antigens adsorbed by brain were present in brain with specific activities less than one-twelfth of the activity of these antigens in N18-SF cells. In total 80% of the Δ(SF-sus) antigens was adsorbed by brain PM in exhaustive procedures.

If the linear regression line is extrapolated, the specific activity of the Δ(SF-sus) antigens in kidney is one-seventh that of brain (1/84th the specific activity of these antigens in N18-SF). However, the kidney adsorption curve appears to saturate at ratios of 0.10 to 0.14. (Larger adsorption ratios were difficult to examine because of nonspecific affects of large amounts of PM.) Tissues other than brain might be expected to contain small amounts of neural antigens due to their intrinsic innervation. If the kidney adsorption curve does saturate at 50%, then (i) approximately 30% of the Δ(SF-sus) antigens cannot be detected by this exhaustive adsorption method in any organ but brain; (ii) half the Δ(SF-sus) antigens are enriched in brain by a factor of seven to one hundred or more when compared with other organs, and (iii) the remaining 20% cannot be detected in any of the organs tested, including brain. Similar calculations, based on complement fixation[11] and saturation binding analysis, suggest that the set of antigens unique to morphologically differentiated N18 cells is present in at least 100 times the specific activity on such cells as on morphologically undifferentiated neuroblastoma cells (N18-sus, 10D or 10D-SF).

Table 3 Antigen classes of murine neuroblastoma cells

Proposed antigen class on:	Presence of antigen on: HeLa	Liver Spleen and so on	Brain	N18-sus	N18-SF
Undifferentiated cells					
I Common Mouse	−	+	+	+	+
II Neural	−	−	+	+	+
III Cell-Specific	−	−	−	+	+
Differentiated cells only					
IV Neural-specific	−	−	+	−	+
V Cell-specific	−	−	−	−	+

−, Will not adsorb; +, will adsorb.

Proposed antigen classes

The xenogeneic antiserum we used revealed a spectrum of particulate antigens on N18 neuroblastoma cells. Morphologically undifferentiated cells have antigens which seem to be shared by all mouse organs and histocompatibility types. They are the mouse common antigens (type I in Table 3). Antibodies to these antigens can be removed from the antiserum by adsorption with PM from either brain, liver or spleen.

Antibodies to the second class of antigens present on morphologically undifferentiated cells can be removed only by adsorption with particulate preparations from brain, and not by any other organs tested. By this criterion and also by direct binding studies, these are neural antigens (type II in Table 3).

Antibodies to the third class of antigens present on morphologically undifferentiated N18 cells are not adsorbed by any of the organs tested. These constitute type III and may be the result of cellular adaption to culture. They may be present only on the tissue (sympathetic nervous system) or cell of origin of the tumour. They might even be related to the malignant transformation of these cells and (or) to their associated A type virus particles[15]. These antigens are called cell-specific in Table 3.

Adsorption experiments demonstrated that morphologically differentiated N18 cells possess all these classes of antigens. In addition, such cells also have antigens related specifically to their morphological differentiation. Approximately half to two-thirds of the antibodies unique to morphologically differentiated cells are adsorbed only by PM from brain (type IV in Table 3). The remainder of the antibodies to antigens unique to morphologically differentiated cells are similar to the third class of antigens described here in that they are not adsorbed by any mouse organ or cell (including 10D-SF) except N18-SF (type V). We hope subcellular fractionation techniques and (or) tolerance inducing methods will facilitate the production of more specific antisera that may be used for detailed study of individual antigenic correlates of morphological differentiation of the murine neuroblastoma in culture.

We thank B. Konya, S. Redmond and P. Tyson for technical assistance, and Dr John Fahey for critical review. This work was supported in part by a contract between the US Atomic Energy Commission and the University of California. R.A. was supported in part by a National Institute of Mental Health training grant.

Age of early Acheulian industries from the Peninj Group, Tanzania

Glynn Ll. Isaacs
Department of Anthropology,

Garniss H. Curtis
Department of Geology and Geophysics, University of California, Berkeley, California 94720

Geophysical data strongly indicate that stone assemblages, which include bifaces and cleavers, from East Africa, are at least a million years old. Since these artefacts seem to be much older than any of their known counterparts in Europe, the question of the date of man's expansion from the tropics into cool, temperate regions is raised for discussion.

ONE of the most long lasting and widespread classificatory entities in human prehistory is the set of stone industries collectively known as Acheulian[1-3]. These industries are characterised, among other things, by the prominence of a series of tools variously called 'bifaces' or 'hand axes'. Representative assemblages are widely distributed; they occur in most regions of Africa, in southern and atlantic Europe, in the Levant and across into peninsular India. Isolated finds referable to the Acheulian have been reported from northern and central Europe, and from continental Eurasia, but north-east of the Alps, Caucasus, Zagros and Himalayan chains of mountains this kind of industry is conspicuously absent or at best rare and atypical.

With regard to age, it has long been known that the Acheulian industrial pattern was in practice through much of that rather vague segment of geological time classified as the 'Middle Pleistocene', though some of the last Acheulian assemblages to be made, belong in the early part of the 'Upper Pleistocene'. The upper and lower boundaries of the 'Middle Pleistocene' are not well fixed stratigraphically and evaluations of their age in years have been highly uncertain and variable from region to region. Consequently estimates of the time span represented by the Acheulian have also been varied and uncertain. In particular the relative age of early representatives of the industry from different regions has been in doubt.

We are reporting here new geophysical evidence from East Africa which provides strong indications of the chronometric age of early Acheulian assemblages in that subcontinent. The evidence raises very important questions with regard to inter-regional correlations and with regard to the timetable for changing patterns in the biogeography of early man. Although we raise these issues, their resolution must lie in part in the application of geophysical techniques to artefact-bearing sections other than those in East Africa.

The new data come primarily from a group of sedimentary and volcanic formations in Northern Tanzania, namely that of the Peninj, west of Lake Natron. The evidence consists of potassium-argon dates and palaeomagnetic determinations based on samples interstratified with artefact-bearing horizons. Although we are continuing to elaborate and check the evidence, the main features of the results seem sufficiently well established to warrant summary publication.

The Peninj Group

In an area about 50 miles north east of Olduvai, on the west side of Lake Natron a long sequence of sediments and volcanics has yielded a hominid fossil, mammal fossils, early Acheulian assemblages and geophysical evidence for dating. The regional sequence has previously been described[4,5] but is summarised here in Fig. 1 and Table 1. A series of K-Ar age determinations has been made by one of us (G.C.) and is also shown in Table 1.

Assemblages of early Acheulian artefacts were obtained by excavation from two localities in the northern sector of the 40 km strip over which the sedimentary sequence has been studied. The archaeological horizons were stratified within the Humbu Formation and in each case the artefacts closely overlie a major basaltic tuff unit.

One of the units dated by K-Ar, the 'Wa-Mbugu basalt' is an olivine basalt flow bedded within basaltic tuffs of the Humbu Formation some 15–20 km to the south of the sites. Another dated flow, the 'intra Moinik basalt', is stratified within the base of the overlying Moinik Formation in outcrops about 8 km to the north. Unless the stratigraphic boundary between the Humbu Formation and the Moinik Formation is markedly time-transgressive from north to south, these two units bracket the age of the Acheulian occurrences. Field relations and the nature of the contrast between the two units make time transgression seem unlikely. In any event, the two flows clearly are close in age to the age of the Acheulian industry. An australopithecine mandible was recovered from beneath the basaltic tuffs and is definitely older than both flows[6,7].

Potassium-argon age determinations

Table 1 shows the results of K-Ar and palaeomagnetic determinations made on various volcanic rocks from the West Natron succession. These K-Ar measurements were made by the standard techniques in use in the Berkeley K-Ar laboratory[8]. The palaeomagnetic results were obtained by T. Reilley working in Nairobi on samples collected by Isaac and Musset[9]. Although there is a fair degree of concordance between stratigraphy and K-Ar ages, the results do not show complete internal consistency

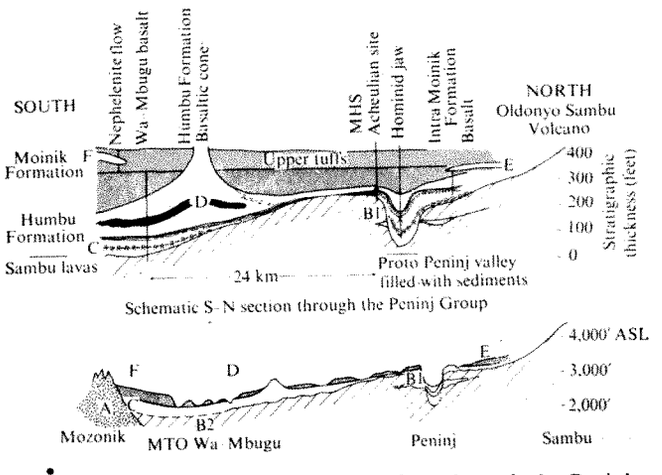

Fig. 1 Diagrammatic north-south sections through the Peninj Group in the West Natron area. The upper section shows the disposition of stratigraphic units without regard to topography. The lower section indicates topographic relations. Letters refer to lava flows listed in Table 1. (For a map see ref. 4, Fig. 1.)

Table 1 Potassium-argon and magnetic polarity determinations made on the succession of volcanic rocks in the West Natron area

Stratigraphic unit and rock type	Run number	K (wt %)	Radiogenic Ar[1]	Radiogenic Ar (%)	Apparent age × 10^6 (Myr)	Polarity	Degree of alteration
Moinik Formation							
(F) Nephelinite	KA 1814f	Grossly inconsistent with stratigraphy				R	
intra Moinik basalt	KA 2410	1.02	0.210	14.4	1.33 ± 0.05	?	5% zeolite
(E)	KA 2589	1.01	0.249	10.6	1.38 ± 0.09	?	
Humbu Formation							
(D) Wa-Mbugu olivine basalt (1964 sample)	KA 1754	0.729	0.200	26.0	1.55 ± 0.03	N	3–5% analcime
	KA 1754R	0.729	0.294	10.7	2.27 ± 0.06	N	
Wa-Mbugu olivine basalt (1969 samples)	KA 2382	0.812	0.181	5.7	0.96 ± 0.10	N	10–15% zeolite
	KA 2382R	0.678	0.220	2.1	1.21 ± 0.36	N	10–15% zeolite
	KA 2578	0.765	0.132	2.7	0.97 ± 0.25	N	10–15% zeolite
	KA 2646	0.750	0.161	6.9	1.21 ± 0.10	N	10–15% zeolite
(C) Hajaro basalt	Too altered for dating purposes					R	
Sambu lavas							
(B_1) Basalt from Peninj Gorge	KA 1755	0.949	0.321	15.4	1.90 ± 0.07	N	~2% zeolite
	KA 1755R	0.949	0.298	18.6	1.77 ± 0.04	N	
(B_2) Basalt from Malambo Gorge	KA 2570	0.579	0.361	4.9	3.50 ± 0.46	R	
Mozonik Volcanics							
(A) Biotite lava	KA 1757	6.86	3.88	18.4	3.18 ± 0.08	?R	
Results grossly inconsistent with stratigraphy:							
(F) Moinik Formation nephelinite	KA 1814	5.84	4.82	40.3	4.60 ± 0.07	R	
	KA 2250	6.27	2.99	49.4	2.68 ± 0.06	R	

and some interpretation is necessary. Palaeomagnetic data for several of the lava flows provide valuable control in assessing the reliability of the apparent ages.

R. L. Hay has carried out petrographic and X-ray diffraction examinations of several of the samples in order to assess the degree of alteration. Of the samples used in runs KA 2382, 2578 and 2646 in a letter, he reports as follows: "A little of the zeolite is isotropic (= analcime ?) but most is weakly birefringent. A diffractogram indicates a substantial amount of phillipsite which is presumably the birefringent zeolite". Hay's estimates of the overall percentage of zeolites are shown in Table 1. There are indications that the most heavily zeolitised lavas may be giving anomalously young ages.

Interpretation of the individual measurements must now be discussed. The oldest unit dated is the Mozonik Volcanics for which biotite flakes from tuffs give an age of 3.2 Myr (KA 1757). A lava flow elsewhere on Mount Mozonik showed reversed polarity and presumably part of the volcano's active life belonged in the Gilbert Reversed Epoch.

The Sambu lavas consist of a thickness of more than 1,000 feet of basalt flows apparently originating from Oldoniyo Sambu (Fig. 1). These lapped around the Mozonik volcanic centre. The flows have normal polarity except for thin localised flows at the very top of the succession. During an interval between a lower set and an upper set of flows, a major canyon was cut and filled with sediments. Under chronological scheme A in Fig. 2 the dates of 3.5 ± 0.46 Myr would be accepted and the dates of 1.9 and 1.77 Myr (KA 1755 and 1755R) for one flow in the upper set would be regarded as erroneous and the whole sequence assigned to the Gauss Normal Epoch. Under scheme B, the younger K-Ar results would be accepted as being consistent with an Olduvai event age. The first interpretation seems to be in better accord with the large scale of the formation.

The Wa-Mbugu basalt is bedded within the Humbu Formation at a level correlated with basaltic tuffs that overlie the australopithecine mandible and underlie the Acheulian industry. This single localised flow consistently showed normal polarity. A scatter of K-Ar apparent age values has been obtained, which seem to fall into two groups. A sample which showed only relatively slight alteration has given ages with a mean of 1.91 Myr (1754 and 1754R) whereas two samples with 10–15% of zeolite yield apparent ages between 0.96 and 1.21 Myr (2382, 2382R, 2578 and 2646). If the older dates are accepted an Olduvai Event age is implied, if the younger ones are accepted—a Jaramillo Event age.

Two runs on a sample of the intra Moinik Formation basalt flow have produced consistent results with a mean of 1.35 Myr (2410, 2589). Unfortunately the polarity of this unit is unknown since all samples collected turned out to have been struck by lightning.

In the southernmost exposures a nephelinite flow is stratified within the upper tuff complex of the Moinik Formation, well above the equivalent level of the artefacts. This flow has reversed polarity (Site MZN113 of Reilley[9]) but attempts at K-Ar dating have produced anomalous results—2.6 and 4.6 × 10^6 Myr. Nephelinites, in our experience and in that of other laboratories, frequently give unreliable results and attempts to date this rock have been abandoned. The polarity evidence is, however, of great importance in evaluating the other determinations. Since the nephelinite with reversed polarity is stratified above the Wa-Mbuga Basalt in the same sections, the normal polarity of the basalt cannot pertain to the Brunhes Normal Epoch but must belong to the Jaramillo or Olduvai Events, as implied also by the K-Ar results.

Figure 2 shows alternative chronologies for the Peninj Group. Alternative A involves acceptance of the date of 1.35 Myr for the intra Moinik basalt and the older set of ages for the Wa-Mbugu Basalt. Under this scheme the 1.77–1.9 Myr age for a Sambu lava flow must be rejected as stratigraphically inconsistent. Alternative B depends on rejection of the intra Moinik basalt date of 1.35 Myr and acceptance of the younger scatter of dates for the zeolitised Wa-Mbuga Basalt samples. We regard alternative A as more likely to prove correct.

While this paper was being revised, McIntyre, Mitchell and Dawson[10] reported K-Ar dates for volcanics from the area immediately to the south of the Natron basin. They conclude that major movements occurred along the Manyara-Natron

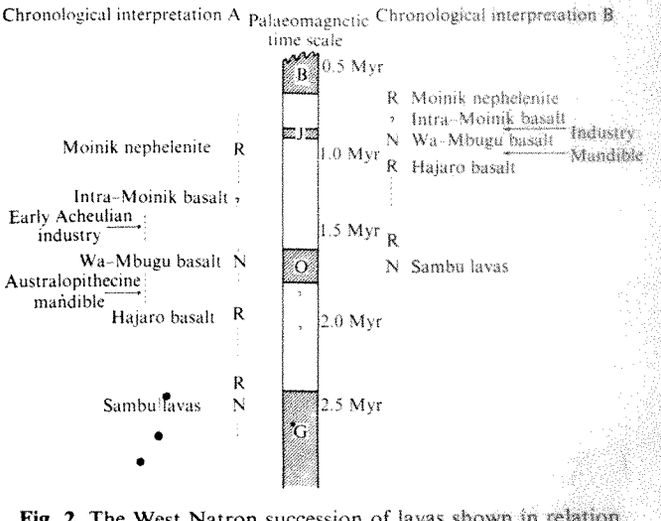

Fig. 2 The West Natron succession of lavas shown in relation to two alternative patterns of correlation of the available potassium-argon and palaeo-polarity data. Alternative A is favoured—see text.

Table 2 K-Ar or palaeomagnetic age determinations for Acheulian sites

Industry	Site	Apparent age × 10^6 (Myr)	Comments and Source
Late Acheulian	Kapthurin	<0.02	Ref. 24
Acheulian	Torre in Pietra	≤ 0.429	Mean of 7, ref. 8
Acheulian	Olorgesailie	0.425	Ref. 25
Lower Acheulian and Developed Oldowan	'Ubeidiya	≥ 0.64	Ref. 21
		≥ 0.68	
Acheulian	Kariandusi	0.928	Ref. 9
		0.946	
		1.1	
Lower Acheulian	Olduvai EFHR	~1.4	(palaeomagnetic) Ref. 16

This list is restricted to instances where the sample source is closely associated with the formation in which the sites are stratified. Several of these dates are problematic. For a general review see ref. 23.

fault between 1.15 and 1.2 Myr ago. This episode almost certainly corresponds to the fault dislocations which terminated the accumulation of the Humbu and Moinik Formations along the western flanks of the Natron basin. The new information lends strong support to chronological interpretation A.

Taken as a whole the geophysical data seem to be unambiguous in their indication of an age of the order of 1.0 to 1.5 Myr for the early Acheulian sites in the Humbu Formation. Table 2 lists other Acheulian occurrences, dated by K-Ar or polarity stratigraphy. The extreme paucity of data is apparent and it is for this reason that we have reported our results in spite of their lack of precision.

In addition to the K-Ar age determination there are a number of uranium decay series measurements on carbonates associated with Acheulian industries, for example those of the Riviera and the Casablanca region[11], the Afar[12] and Isimila in Tanzania[13]. Where these methods have given rise to finite age estimates they are less than 300,000 yr. In most instances the associated industry is a 'Middle' or 'Late' Acheulian, so that the uranium series dates do not at present contribute to the problem of estimating the age of the early Acheulian. Some geochemists have important reservations about regarding Th-U measurements on many materials, as 'dates'[14].

Implications

Whichever alternative chronology is adopted from Fig. 2, the age estimates for the Humbu Formation industries are very much greater than the values commonly entertained for the earliest Acheulian in the Mediterranean basin or Europe where estimates based on stratigraphic considerations commonly range between 300,000 and 500,000 yr. And yet the combined evidence of the various East African sections gives a very strong indication that at least some stone tool kits of Acheulian type began to be made in East Africa more than a million years ago. The Olduvai evidence reported by M. D. Leakey[15] and by Brock, Hay and Brown[16] is unambiguous in its demonstration that the earliest Acheulian assemblages are of Matuyama Reversed Epoch age (that is $\geq$ 0.7 Myr), and the K-Ar dates and stratigraphy of the Olduvai sections like the Natron section implies an age of between 1.0 and 1.6 Myr.

Until recently it seemed possible that the apparent discrepancy between East Africa and Europe was caused primarily by a tendency of European stratigraphers to undervalue the duration of the 'Middle Pleistocene', but recent palaeomagnetic work has resulted in the determination of the position of the Brunhes-Matuyama boundary in two important European Pleistocene sections—namely, those of the Netherlands and of Poland. Expressed in biostratigraphic and climate-stratigraphic terms, the boundary has been found by Mont-Frans to lie in the lower portion of strata classified as 'Cromerian' in the Netherlands[17] and Kukla has located it in the early Biharian of Poland[18]. The oldest stone tool assemblages which contain hand axes in Europe, however, are normally assigned to the 'Elster' (or Mindel) stratigraphic complex which succeeds the 'Cromerian'.

Evidence for hominid occupancy of Europe before Elster–Mindel times is very scanty with the allegedly late Villafranchian site of the Grotte du Vallonet near Nice constituting one of a very few important possible documents[19]. Another possible pre-Mindel occurrence is that of Abbeville, where hand axes were collected by D'Ault du Mesnil in 1875–96 (ref. 20). These may have been of late Cromerian age, but full stratigraphic information is not now available.

The 'Ubeidiya Formation contains what seem to be the oldest geophysically-dated artefacts in Eurasia. Lava flows believed to be stratigraphically above Acheulian and Developed Oldowan occurrences, have been dated at 0.64 and 0.68 Myr (ref. 21).

Palaeomagnetic stratigraphy has not yet been reported for such important Mediterranean basin sequences as those of Latamne (Syria), Ternifine (Algeria) or Sidi Abder Rahman (Morocco). The Indian sites are similarly unknown geochronological quantities, though new work in Java may soon throw light on the age of the apparently 'non-Acheulian' *Homo erectus* population there[22].

If, as seems likely, further work substantiates the present indications of an antiquity of a million years or more for the earliest East African Acheulian assemblages, and, if the apparent ages of less than half a million years are sustained for Europe, then understanding of the timing of developments in human cultural geography will have to be profoundly modified. It will be necessary to consider the possibility that hominids were essentially restricted to tropical and warm temperate zones for a much larger fraction of their evolutionary history than has hitherto been envisaged. For these questions to be resolved it is urgent that there be an intensification of efforts to secure chronometric determinations and palaeomagnetic data from Middle Pleistocene, artefact-bearing sedimentary sequences in areas outside East Africa.

The research at Peninj was a joint undertaking with Richard E. Leakey. The Tanzanian government kindly gave its permission and encouragement. Financial support came initially from the National Geographic Society and latterly as part of a National Science Foundation Grant. The final stages of the work was done during tenure by one of us (G.L.I.) of a Miller Professorship in the University of California. Dr Mary Leakey read a draft report and kindly gave advice.

Mechanism of action of the toxic lectins abrin and ricin

Sjur Olsnes, Karin Refsnes and Alexander Pihl

Norsk Hydro's Institute for Cancer Research, Montebello, Oslo 3 Norway

The mechanism of action of the plant toxins abrin and ricin is described. The toxins inhibit protein synthesis probably by inactivating the 60S ribosomal subunits, interfering with chain elongation. Only eukaryotic ribosomes are attacked by the toxins.

PROTEINS toxic to animal cells are widely distributed but in only a few cases is their mechanism of action at the cellular and molecular level known in detail. Recently, considerable progress has been made in work on the toxic proteins abrin and ricin, whose mechanism of action is now rather well understood. The facts learned about the binding of abrin and ricin to cell receptors and their subsequent uptake into cells is of considerable general interest, since recent evidence suggests that similar mechanisms may apply in the case of other toxic proteins and possibly also in the case of some protein hormones and growth factors.

Abrin and ricin, which are present in the seeds of *Abrus precatorius L.* (Leguminosae) and *Ricinus communis* L. (Euphorbeaceae) respectively, have been known since the end of the last century (for review see ref. 1). Previously it was thought that the toxic action of these proteins in animals is due to the strong haemagglutinating properties of abrin and ricin preparations. More recent work has shown, however, that the agglutinating activity is associated with closely related, nontoxic agglutinins present in the same seeds[2-7] and that the highly purified toxins possess little or no agglutinating ability. Abrin and ricin have been reported to be more toxic to malignant than to normal cells and attempts to treat cancer in animals and man with abrin and ricin have been reported[8].

Structure

Abrin and ricin are glycoproteins with molecular weights of 60,000 to 65,000 (refs 2, 4, 7, 9–11) (Fig. 1). The whole toxins move as single bands in polyacrylamide gels in the presence of sodium dodecyl sulphate, but on treatment with 2-mercaptoethanol, they are split into two peptide chains[5,6,9-11], moving at rates corresponding to molecular weights between 30,000 and 35,000 (Table 1). Thus, the toxins consist of an A and B chain, joined by SS bonds (Fig. 1). We have separated the two peptide chains in their native form by ion exchange chromatography[5,6]. The isolated peptides thus obtained are not contaminated to any significant extent with the other chain. If a mixture of the isolated A and B chains is dialysed to remove 2-mercaptoethanol, the disulphide bridges between the two chains are reformed (S.O., A. M. Pappenheimer, and A. A. Harper, in preparation). The reconstituted proteins are almost as toxic as the native proteins (Table 2), demonstrating that the peptide chains do not lose their activity during the separation. Hybrid proteins consisting of the A chain of abrin and the B chain of ricin and *vice versa*, were also prepared (S. O., A. M. Pappenheimer, and A. A. Harper, in preparation). Such hybrids have toxicities close to those of the native toxins (Table 2).

Both toxins consist of a neutral and an acidic peptide chain (Table 1). In the case of abrin, the A chain is acidic, whereas in ricin the B chain has the low *p*I value. In both toxins the

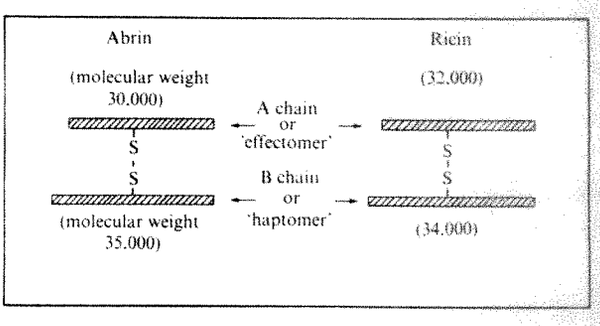

Fig. 1 Schematic structure of abrin and ricin.

B chains contain most of the carbohydrates (Table 1).

The structure and properties of abrin and ricin are surprisingly similar although they come from the seeds of two unrelated plants. Although the toxins are immunologically different (refs 5, 6 and 12 and S. O., K. R., A. P., and T. Christensen, in preparation) and show differences in their amino-acid composition (in preparation) the many similarities suggest that the toxins descend from a common ancestor molecule.

Effect *in vivo*

Abrin and ricin are extremely toxic to animals and man. After intraperitoneal administration the LD_{50} doses in mice were 40 ng and 100 ng for pure abrin and ricin, respectively[5,6]. These very small doses lead to death in the course of a few days, whereas larger doses have a more rapid effect. But animals never die earlier than 8–10 h after intraperitoneal administration of toxin. In animals intoxicated with large doses, haemorrhages in the viscera and serous cavities are found, whereas in animals treated with smaller doses multifocal necrosis develops in the parenchymous organs and in the germinal centres of the lymphatic organs[13]. Previous work revealed little or no change in oxygen consumption and energy metabolism, and the serum concentration of various metabolites studied remained unchanged in the early stage of intoxication[14].

Table 1 Physical properties of abrin, ricin and their constituent peptide chains

Toxin	Molecular weight*	*p*I†	Carbohydrate content‡
Abrin	65,000	6.1	—
Abrin A chain	30,000	4.6	0
Abrin B chain	35,000	7.2	7.4
Ricin	65,000	7.1	—

†Measured by isoelectrofocusing (S. O., K. R., A. P., and T. Christensen, in preparation).
‡In % (w/w). Measured by gas chromatography (S. O., K. R., A. P., and T. Christensen, in preparation).

The selective inhibition of protein synthesis by abrin and ricin was first shown by Lin *et al.*[14,15] and our data in Fig. 2 confirm their experiments. It is shown that when 1-ml samples of Ehrlich ascites cells were treated with 0.1 μg of the toxins, the incorporation of ^{14}C-leucine into acid-precipitable material decreased after a lag time of about 30 min and stopped after 2 h (Fig. 2*a*). The incorporation of labelled thymidine was also inhibited by this concentration of the toxins (Fig. 2*b*), although after a longer lag time. On the other hand, the incorporation of ^{14}C-uridine was only slightly inhibited by 0.1 μg ml^{-1} of the toxins (Fig. 2*c*).

Different functions of the two peptide chains

The toxic effect *in vivo* seems to depend on the intact structure of the toxins[16]. Thus, we found that the isolated peptide chains had only ~ 1% of the inhibiting effect on protein synthesis in cells compared with that of the intact toxins (data not shown). A similar relationship was found when the toxic activity was tested in living animals (Table 2). A mixture of the two chains (reduced toxins) had the same low effect as isolated A or B chains. As pointed out above, reconstituted toxins or hybrid proteins show about the same toxicity as native abrin and ricin. (S. O., A. M. Pappenheimer, and A. Harper, in preparation).

* The cell-free system (0.5 ml) was an unfractionated rabbit reticulocyte lysate to which was added salt solution, an energy donating system, ^{14}C-leucine and the 19 other (unlabelled) amino acids. The system is essentially that of Lingrel as described elsewhere[21].
† Washed human erythrocytes (blood group B$^-$) were mixed with toxins or their peptide chains in 1 ml of 10 mM Tris-HCl (*p*H 7.5), 0.14 M NaCl for 60 min at 20° C. Then 5 μl of antiabrin or antiricin was added and the samples were observed under the microscope after 9 h. Conditions as described elsewhere[5,6].
‡ The amount giving 50% death when injected intraperitoneally into mice as described elsewhere[5,6].
§ Measured after 60 min incubation at 30° C.
¶ Pretreated with 1% 2-mercaptoethanol overnight at 4° C.
‖ Equimolar amounts of A chain and B chain were mixed and dialysed to remove 2-mercaptoethanol and reoxidise the disulphide bridge as described elsewhere (S. O., A. M. Pappenheimer, and A. Harper, in preparation).

The results indicate that only molecular species consisting of A and B chains joined by disulphide bridges have toxic effects on intact cells and living animals.

When the effect on protein synthesis of abrin, ricin and their constituent peptide chains was studied in a cell-free system from rabbit reticulocytes, we obtained results which in several respects were opposite to those obtained with intact cells[5,6,16]. Thus, reduced toxins, consisting of a mixture of A and B chains were much more potent than the intact toxins (Table 2). Experiments with the isolated chains showed that the inhibitory effect on protein synthesis is associated with the A chain of the toxins, whereas the isolated B chains were comparatively inactive. The results suggest that when the A chain is bound with a disulphide bridge to the B chain, it is prevented from inhibiting protein synthesis in a cell-free system. Possibly, the moderate inhibition observed when intact toxin is added (Table 2) may be accounted for by the fact that the cell-free protein

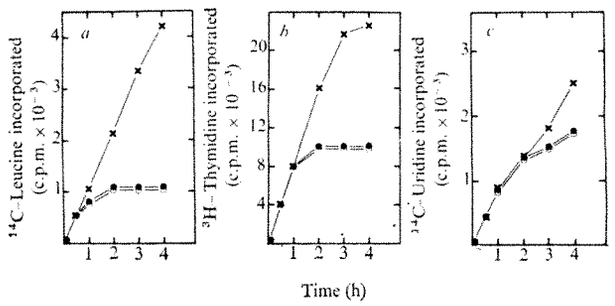

Fig. 2 Effect of abrin and ricin on the synthesis of protein (*a*), DNA (*b*), and RNA (*c*) in Ehrlich ascites cells *in vitro*. Abrin and ricin were extracted and purified to homogeneity as described elsewhere[5,6]. To 1-ml samples of Ehrlich ascites cells, washed and suspended in incubation medium as described elsewhere[19], were added 0.5 μCi ^{14}C-leucine (specific activity 331 Ci mol^{-1}), 10 μCi methyl-^{3}H-thymidine (specific activity 24.5 Ci mol^{-1}) or 0.5 μCi ^{14}C-uridine (specific activity 505 Ci mol^{-1}) as indicated. The samples were incubated at 37° C, aliquots were removed after different times and the acid-precipitable radioactivity was measured as described elsewhere[19] with the exception that in the case of (*c*), the aliquots were poured directly into cold 5% trichloroacetic acid rather than pretreated with 0.1 N NaOH, ×, Control; ○, 0.1 μg abrin; ●, 0.1 μg ricin.

synthesising system contains a low concentration of 2-mercaptoethanol capable of liberating small amounts of A chain.

Since a complete toxin consisting of both A and B chains is required for activity on whole cells, it is clear that the B chain must have a specific function. Our recent experiments indicate that the B chain is necessary for binding the toxins to the cell surface[5,6]. In indirect haemagglutination experiments, where erythrocytes, pretreated with isolated B chain (or intact toxin), were exposed to an antiserum against the toxin (Table 2), the cells agglutinated, indicating that the antibody molecules form bridges between the cells with anchor points in the B chains or intact toxin molecules bound to the cell surface. Under similar conditions, pretreatment of the cells with A chain did not result in agglutination with antiserum, and we have been able to demonstrate this in a more direct way. Sepharose particles possessing covalently bound intact toxins or isolated B chains will bind erythrocytes, whereas particles with bound A chains will not (Fig. 3).

Binding to surface receptors

The B chains of the toxins probably bind to galactose-containing receptors on the cell surface. We found that the haemagglutination by antisera of erythrocytes pretreated with B chains could be inhibited in the presence of galactose or lactose[7]. Furthermore, in the presence of lactose no erythrocytes became bound to Sepharose particles containing covalently bound toxins (Fig. 3). Also, the ability of abrin and ricin to inhibit protein synthesis in Ehrlich ascites cells is strongly reduced

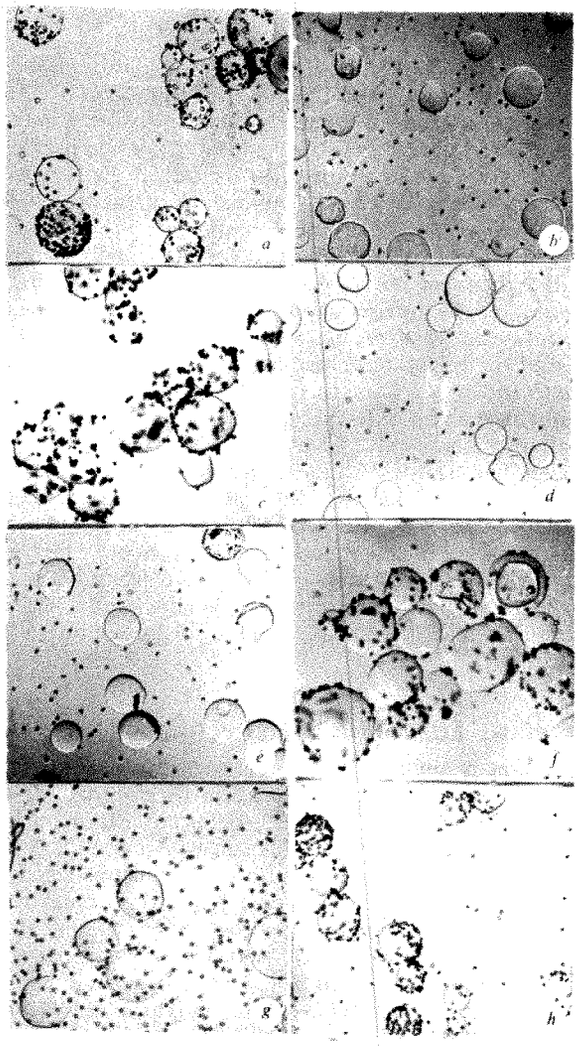

Fig. 3 Binding of erythrocytes to Sepharose particles with covalently bound toxins or B chains. Abrin and ricin or their constituent peptide chains were linked covalently to cyanogen bromide-activitated Sepharose particles, (Pharmacia, Uppsala, Sweden) 10 mM lactose was present during the binding procedure to prevent the toxins from becoming bound by their specific binding sites to galactose residues of Sepharose. Sepharose was washed several times at high and low *p*H and with 0.1 M lactose to remove unbound material. It was then washed extensively with 0.1 M sodium phosphate (*p*H 7.1) containing 0.14 M NaCl and subsequently it was resuspended in the same buffer. One drop was mixed with about 10^7 human erythrocytes and mixed carefully by gentle shaking. Where indicated, 10 mM lactose was added. The mixture was examined under the microscope. *a*, Abrin; *b*, abrin (lactose); *c*, ricin; *d*, ricin (lactose); *e*, abrin A chain; *f*, abrin B chain; *g*, ricin A chain; *h*, ricin B chain.

when lactose is present in the culture medium (Fig. 4). In the presence of 10 mM lactose about twice as much abrin was necessary to reduce the protein synthesis by 50% as when lactose was omitted, and in the case of ricin about 30 times the concentration of toxin was required to obtain the same toxic effect as in the absence of lactose. Similar data have been obtained with ricin by other authors[17]. Evidence that only the B chain is involved in the binding of the toxins to galactose was obtained in experiments where we applied isolated chains of the toxins to a column of Sepharose 4B (which contains galactose residues). In this case the A chain passed through the column, whereas the B chain was retained and could be eluted with galactose[6]. The ability of the toxins to bind to Sepharose columns has been utilised in several laboratories for the purpose of purification of the toxins[5,6,10,17].

The toxins seem to have one binding site for galactose-containing carbohydrates, whereas the nontoxic agglutinins present in the same seeds have two binding sites[7]. Thus we found in equilibrium dialysis experiments that each toxin molecule binds one molecule of lactose, whereas the agglutinins bind two lactose molecules per molecule. Abrin and ricin may therefore be considered as monovalent lectins. The binding constants were 8×10^3 l mol^{-1} (abrin) and 1.5×10^4 l mol^{-1} (ricin).

On the surface of different cells about 1×10^7 to 2×10^7 sites to which the toxins can bind seem to be present[17,18]. The presence of a higher number of sites on the surface of malignant cells than on their normal counterparts may in part explain why abrin and ricin seem to be more toxic to malignant than to normal cells[18].

Penetration of the toxins into cells

Since the B chains seem to bind the toxins to the cell surface we shall call this chain the 'haptomer' (Fig. 1). The A chain which carries the toxic activity, is denoted as the 'effectomer'. It is likely that after the toxins are bound to the cell surface by the haptomer, the A chain (or possibly the whole toxin) is transported into the cytoplasm to its site of action, the ribosomes (see below). It should be noted that whereas in a cell-free system protein synthesis is inhibited immediately after addition of the toxins[5], we always found a lag of at least 30 min (at 37° C) when cells in culture were treated with the toxins, even

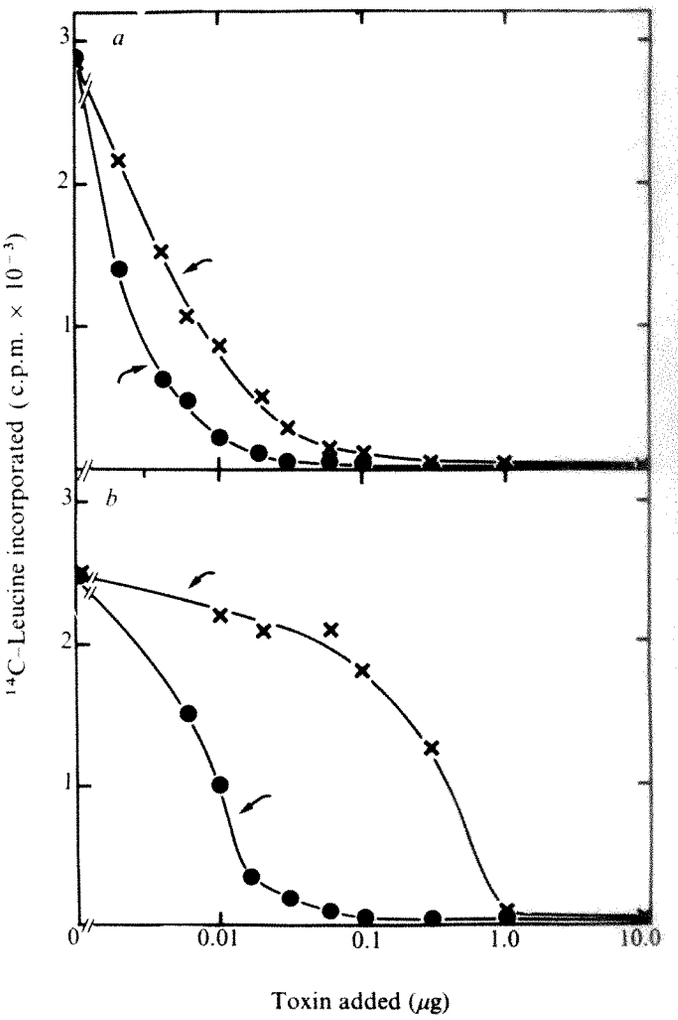

Fig. 4 Effect of lactose on the ability of abrin (*a*) and ricin (*b*) to inhibit protein synthesis in Erhlich ascites cells. To 1-ml samples of a solution of Ehrlich ascites cells were added increasing amounts of toxin as indicated in the absence (●), and presence (×) of 10 mM lactose. The samples were incubated as in Fig. 2*a* and after 1 h, 0.5 μCi of ^{14}C-leucine was added to each tube. The samples were further incubated for one more hour. Then aliquots were removed from each sample and the acid-precipitable radioactivity was measured.

Table 3 Protective effect of antitoxins added to Ehrlich ascites cells at different times after abrin and ricin

Time of toxin interaction with the cells before addition of antitoxin min	Inhibition of protein synthesis Abrin %*	Ricin %*
0	0	0
5	33	11
10	67	44
30	92	78
60	100	100

To 1 ml samples of a suspension of Ehrlich ascites cells prepared as in Fig. 2*a* was added 1.0 μg of abrin and ricin. After incubation at 20° C for the indicated periods of time, a neutralising amount of antiabrin and antiricin was added. The samples were incubated at 20° C for a total of 60 min, then the incubation was continued at 37° C for 2 h to enable the effect of the toxins to develop (see Fig. 2). ^{14}C-Leucine (0.5 μCi) was then added and the acid-precipitable radioactivity was measured as in Fig. 2*a*.

* Percentage reduction in radioactivity incorporated (control: 4,500 c.p.m.).

when the toxin concentration of the medium was as high as 100 μg ml^{-1} (ref. 19). This lag is greater at lower temperatures (being 6 h at 20° C). Since the binding of the toxins to the cell surface seems to be rapid, in seems that the transportation of the toxin (or the free A chain) into the cytoplasm accounts for most of the lag. Our finding (Table 3) that the toxic effect can be counteracted by antitoxins only during the first 30 min of the 6 h lag at 20° C, indicates that during the remaining 5.5h the toxins are not exposed on the outside of the cells.

They are possibly engulfed by endocytotic vesicles from which they are slowly liberated into the cytoplasm. It is generally believed that such vesicles merge with lysosomes. Our recent finding that the toxins are extremely resistant to proteolytic enzymes may be significant in this respect (S. O., K. R., and A. P., in preparation). The view that the cellular uptake of abrin and ricin involves endocytosis is supported by our finding that these toxins are unable to inhibit protein synthesis in reticulocytes which have little or no endocytotic activity[19], even though the toxins bind readily to the surface of these cells. It is interesting to note that many viruses are taken up by a similar mechanism in that they bind to specific receptors on the surface of susceptible cells (viropexis) and are then transported into the cytoplasm by endocytotic activity.

Mechanism of protein synthesis inhibition

The A chains of abrin and ricin have an immediate inhibitory effect on protein synthesis in a cell-free system from rabbit reticulocytes[5,6]. To see whether abrin and ricin act on the ribosomes or on some soluble factors, we fractionated the lysate into ribosomes and a postribosomal supernatant, which were incubated separately with and without A chains from abrin and ricin[20]. After incubation, the toxins were inactivated by addition of sufficient amounts of specific antitoxins. Subsequently, the ribosomes and the supernatants were recombined and a cell-free protein synthesising system was prepared. When the ribosomes had been pretreated with the toxins, virtually no incorporation of labelled amino acids into protein occurred, whereas pretreatment of the supernatant did not inhibit the amino acid incorporation. The fact that abrin and ricin inactivated isolated ribosomes indicate that a cofactor is not necessary. Our results indicate that only the eukaryotic type of ribosome is susceptible to the toxins, as protein synthesis in a cell-free system from *Escherichia coli*[20] was not reduced, whereas the incorporation of labelled amino acids into proteins in a cell-free system from rat liver[20] and wheat germ (our unpublished work) was strongly inhibited.

Not only protein synthesis directed by natural messengers, but also poly(U)-directed polymerisation of labelled phenylalanine, is inhibited[21]. The inhibition was strongest in the presence of a low concentration of Mg^{2+} ions (4 mM) and could be partly overcome by increasing the concentrati (our unpublished data).

In a cell-free system the toxins seem to inhibit the elongation of already initiated peptide ch sucrose gradient centrifugation we found that whe of new peptide chains was inhibited, the polysom preserved if the incubation was carried out in th the toxins and that the toxins prevented the runoff ordinarily observed under such conditions[21,22].

When the ability of isolated ribosomes to suppo tion of radioactive puromycin into acid-precipit was measured, no difference was found whether or ribosomes had been preincubated with the tox published results). Similar findings were made by *et al.*[23] and by L. Carasco (personal communi data obtained so far thus indicate that the toxins d formation of the peptide bond.

Recent findings of Montanaro *et al.*[23] indica inhibits the ribosome-linked GTP hydrolysis catal and Sperti *et al.*[24] have obtained evidence that the 6 subunit is the site of action of ricin. Data from our tory indicate that abrin also inactivates the 60S s likely therefore that the toxins act by modifying t somal subunits in some way, rendering them un with EF2.

Enzymatic activity of the effectomer

The minimum amount of abrin and ricin nece HeLa cells in culture was estimated to be less th molecules per cell (unpublished data). Since cells contain about 10^5 to 10^6 ribosomes and sinc that a substantial fraction of the ribosomes must b to kill the cells, we inferred that the toxins s catalytically[16]. This view is supported by our fin cell-free systems thousands of ribosomes were inact 30 min by one toxin molecule[5,6,16]. Our subsequent the inactivation of ribosomes by the toxins is a time ture-dependent process is also consistent with the toxins possess enzymatic activity[20]. The possibi A chains of the toxins activate an enzyme which the the ribosomes, is unlikely since the A chains inacti ribosomes in simple buffer solutions[20]. It is not kn the toxins are specific proteases or specific RNases eukaryotic ribosomes in a similar way as colicin E bacterial ribosomes (for review see ref. 1).

Implications

The finding that the toxic plant proteins abrin and of a haptomer moiety responsible for the binding to surface receptors of susceptible cells and an eff responsible for the specific toxic action, seem to be able interest. Thus, it has prevoiusly been shown tha toxin consists of an enzymatically active A chain wh protein synthesis by inactivating the elongation and a B chain which binds the toxin to specific surface of susceptible cells (for review see ref. 25 is now accumulating that cholera toxin[26], botul and tetanus toxin[28] may similarly consist of a hapto effectomer moiety. Also it seems possible that endocytosis after specific binding to the cell surf widespread in nature. It is an interesting possibilit and ricin pass the cell membrane by routes originall for the uptake of physiological proteins, like certai and growth factors.

Role of myosin light chains in calcium regulation

J. Kendrick-Jones

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK

The evidence that rabbit DTNB light chains bind to 'desensitised' scallop myosin and restore calcium sensitivity, that is, they functionally replace the scallop EDTA light chain, may suggest that these light chains are involved in some type of calcium regulatory mechanism in rabbit myosin in vivo.

In skeletal muscle, contraction is regulated by the interaction of calcium ions with the specific protein troponin, which is attached to the actin filaments[1]. In molluscan muscles[2] and in some primitive invertebrates[3], on the other hand, contraction is regulated by the interaction of calcium with myosin. Molluscan myosin preparations bind calcium and their ATPase activity in the presence of pure actin is calcium dependent[2]. The calcium dependence of the actin-activated ATPase activity of scallop myosin requires the presence of a specific light chain, called the EDTA light chain because it is released from myosin if the divalent cation concentration of the medium is lowered by the addition of EDTA[4]. The release of the light chain results in a loss of calcium sensitivity, that is, the myosin is 'desensitised' and the calcium requirement for the actin activated ATPase activity is abolished. Recombination of the EDTA light chain with the densensitised myosin in the presence of divalent cations restores calcium sensitivity, showing that the light chain functions as a regulatory subunit.

Comparative studies on the calcium regulatory systems of a wide variety of species[3] have revealed that the muscles of some invertebrate species contain both myosin-linked and actin-linked calcium regulation. These results prompted an investigation of a possible role in calcium regulation of the myosin light chains in other species, such as vertebrates, whose muscles seem only to show actin-linked calcium regulation.

The number, size and chemical characteristics of myosin light chains from a variety of vertebrate species and different muscle types are rather diverse[5–13] and, as yet, there is no unambiguous demonstration of the role of the subunits in the functions of the myosin molecule. Rabbit skeletal myosin, the most extensively studied, contains three light chain components and these may be divided, on the basis of chemical studies[14] into two distinct classes—(1) the so-called 'alkali' light chains[15] with molecular weights of 21,000 and 17,000 which have extensive sequence homology[16] and have been implicated in regulation of the enzymatic activity of the myosin[17,18] and (2) the DTNB light chain with a molecular weight of about 19,000, which is selectively released from myosin by treatment with 5,5′-dithiobis-(2-nitrobenzoic acid) (DTNB)[7,15]. In view of the evidence[14] that this DTNB light chain is not required for the hydrolytic activity of the myosin, since its selective removal by treatment with DTNB does not significantly alter the ATPase activity of the residual myosin, a possible role for this light chain in calcium regulation was investigated.

DTNB light chain and rabbit myosin

Treatment of rabbit skeletal myosin with 5,5′-dithiobis-(2-nitrobenzoic acid) (DTNB)[15], which blocks about 80% of the myosin thiol groups, leads to the selective release of 50–60%, (about 1 mol) of the DTNB light chains. Treatment with EDTA alone[4] does not remove the DTNB light chain. The loss of 1 mol of DTNB light chain does not significantly alter the properties of the residual myosin; it has little effect on the ATPase activity or on the ability of the myosin to interact with actin, and a calcium-sensitive complex is formed when this myosin is mixed with actin containing the calcium regulatory proteins troponin and tropomyosin. Similarly, if subfragment 1 is prepared from DTNB-treated myosin by papain cleavage[19], no intact DTNB light chains are detectable by polyacrylamide gel electrophoresis in the presence of SDS (Fig. 1). Double reciprocal plots of the actin-activated ATPase of this subfragment[20] yields a value for V_{max} (12 μmol ATP min^{-1} mg^{-1}) similar to that obtained with subfragment 1 prepared from untreated myosin. This subfragment also interacts with actin containing tropomyosin and troponin to form a calcium-sensitive complex. The functional significance of the DTNB light chain is therefore unclear and its presence is apparently not required for the normal biochemical functions of the

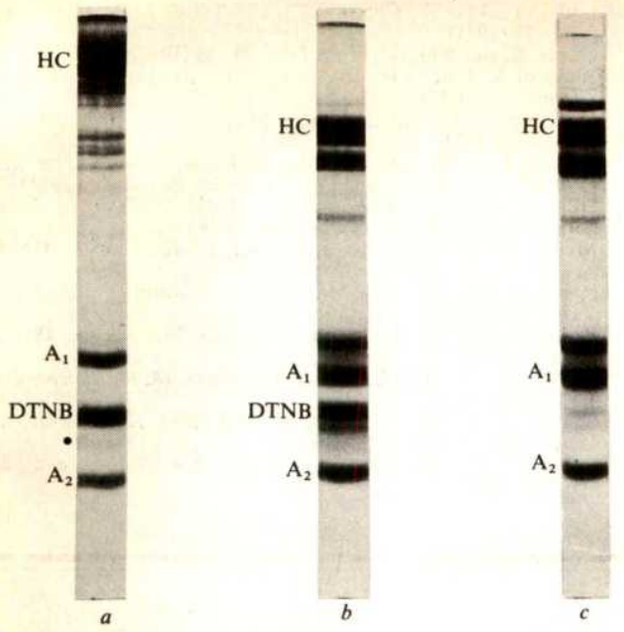

Fig. 1 10% SDS polyacrylamide gel electrophoresis[29] of: *a*, rabbit myosin; *b*, subfragment 1 prepared from untreated rabbit myosin; *c*, subfragment 1 prepared from DTNB-treated rabbit myosin. Buffer system used was 100 mM Tris bicine (*p*H 8.3), 0.1% SDS and the gels were stained with 0.5% Coomassie brilliant blue. myosin. It is difficult to accept that this light chain is a tightly bound contaminant of the myosin, especially in view of the stoichiometric amounts found in myosins from several species[10]. An alternative explanation is that the DTNB light chains in the intact muscle may have a function that has been lost during extraction and purification of the myosin; for example, it may, like the EDTA light chain in molluscan myosin, be involved in some type of calcium regulation. To explore this possibility, the interaction of the DTNB light chain with 'desensitised' molluscan myosin preparations was studied.

DTNB light chain and 'desensitised' molluscan myosin

Treatment of scallop myofibrils, actomyosin or myosin with 10 m M EDTA (ref. 4) leads to the release of 1 mol of the EDTA light chain and to a loss of calcium sensitivity, that is, the preparations are 'desensitised' and the calcium requirement for the actin-activated ATPase activity of the myosin is abolished. Rabbit DTNB light chains were added to preparations of desensitised scallop myofibrils, actomyosin and myosin and the mixtures were washed extensively to remove nonspecifically bound light chains. Polyacrylamide gel electrophoresis in the presence of SDS of these preparations (Fig. 2) shows that the DTNB light chain combined readily with these desensitised preparations. In the case of the desensitised myofibril and actomyosin preparations, the binding of the DTNB light chain always leads to a restoration of calcium sensitivity (Table 1) that is, the DTNB light chain can replace the scallop EDTA light chain. In the case of purified myosin preparations, however, the results are somewhat more complicated. Although the DTNB light chain always binds to the desensitised myosin preparations (Fig. 2), its ability to restore calcium sensitivity to these preparations is rather variable. The results in Table 2 illustrate that the DTNB light chain can in some cases, fully restore calcium sensitivity to the desensitised myosin. In certain other preparations, however, even though the DTNB light chain is bound, the myosin remains completely insensitive to calcium. These desensitised myosin preparations, however, become calcium sensitive when combined with the scallop EDTA light chain. This lack of calcium sensitivity when the DTNB light chain binds to certain desensitised myosin preparations must be due to rather subtle alterations in the structure of the myosin, and indicates that the DTNB light chain requires a rather more 'specific myosin configuration' than the EDTA light chain does, in order to bind in the correct position and restore calcium sensitivity. The reasons for the variability in resensitising myosin with the DTNB light chain are at present unclear. Since the desensitised myofibril and actomyosin preparations can always be resensitised by the addition of the DTNB light chain, the presence of actin in these preparations probably stabilises the structure of the desensitised myosin. We have no evidence to suggest that the DTNB light chain interacts with either the actin or tropomyosin in these preparations.

To measure directly the amount of DTNB light chain bound to the myosin in these desensitised preparations, the light chains were radioactively labelled by alkylating their thiol groups with ^{14}C-labelled iodoacetic acid. This treatment has no effect on the ability of the light chain to bind and to restore calcium sensitivity. Using these labelled DTNB light chains, it was found that calcium sensitivity was completely restored when about 1 mol of light chain is bound per myosin molecule, and the extent of restoration of calcium sensitivity correlates approximately with the amount of light chain bound (Tables 1 and 2). Only 1 mol of DTNB light chains is bound, even when a large excess of light chain is added. These values are consistent with our previous findings[21], that 1 mol of EDTA light chain is released when the myosin is desensitised by treatment with EDTA. These results and the fact that neither intact myofibrils nor myosin bind the DTNB light chain unless the EDTA light chain has been removed, further suggest that the DTNB light chain must bind at approximately the same position on the myosin heavy chains as the EDTA light chain.

Release of the EDTA light chain from scallop myofibril and myosin preparations decreases the amount of calcium bound by the myosin in these preparations by about 40%

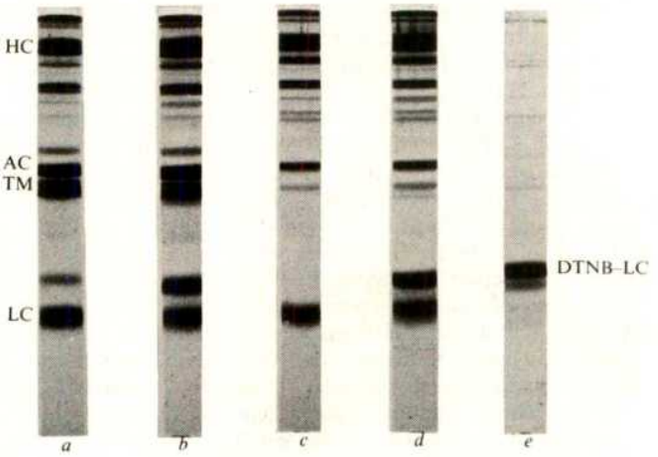

Fig. 2 10% SDS polyacrylamide gel electrophoresis demonstrating the binding of rabbit DTNB light chains to desensitised scallop myofibril and myosin preparations. *a*, Desensitised scallop myofibrils; *b*, desensitised myofibrils plus DTNB light chain; *c*, desensitised scallop myosin; *d*, desensitised scallop myosin plus DTNB light chain, *e*, DTNB light chain. The isolated rabbit DTNB light chain was added in large excess to the desensitised scallop preparations in 40 mM NaCl, 1 mM $MgCl_2$, 5 mM phosphate buffer (*p*H 7.0) and these preparations were washed extensively to remove the unbound light chains. *Assuming that the myosin content of desensitised myofibrils is 65%, the molecular weight of the myosin is 425,000 and that of the DTNB light chain is 19,000.

The desensitised myofibrils were incubated for 10 min with increasing amounts of the ^{14}C-labelled DTNB light chain in 40 mM NaCl, 1 mM $MgCl_2$, 5 mM phosphate (*p*H 7.0) and washed four times with 10 volumes of the same solution. Aliquots were taken for ATPase measurements[4] and for liquid scintillation counting to determine the amount of light chain bound.

(ref. 4). Full calcium binding is regained when the EDTA light chain and the desensitised myosin are recombined (Table 3). When the DTNB light chain is combined with desensitised myofibril and myosin preparations, however, the amount of calcium bound is increased by only 10–20%. This rather lower figure raises the question, especially in view of the results in Table 1 and 2 which indicate that the DTNB light chain can fully restore calcium sensitivity to these preparations, whether there is a correlation between the restoration of calcium sensitivity and the amount of calcium bound. To answer this question, the ATPase activities and the amount of light chain bound by desensitised myofibrils were assayed after the calcium binding measurements. The results in Table 3 indicate that during our calcium binding procedure[4] there was a slight decrease in the amount of DTNB light chain bound (0.89 mol light chain bound per mol myosin) and a decrease in calcium sensitivity (compare Table 1). Therefore, when the DTNB light chain combined with desensitised myofibrils, the restoration of calcium sensitivity seems to parallel the increase in the amount of calcium bound by these preparations.

The DTNB light chain is tightly associated with scallop myosin, since it is not released by repeated reprecipitation or under mild dissociation conditions. The binding of light chain to myosin heavy chain also seems to be specific for the DTNB light chain, since the other types of light chains, that is, the rabbit 'alkali' light chains isolated from DTNB-treated myosin by treatment with guanidine hydrochloride[9] and purified by chromatography on DEAE-cellulose[14] do not bind and do not confer calcium sensitivity to these desensitised preparations. To confirm this observation, rabbit myosin was treated with 5 M guanidine hydrochloride[22] which dissociates the 'alkali' and DTNB light chains, and both types of light chains were added to a desensitised scallop myofibril preparation, which selectively binds solely the DTNB light chain and restores calcium sensitivity. Preliminary evidence indicates that this type of 'regulatory' light chain may be a common feature of all myosins, for example, cardiac, gizzard smooth, lobster and frog striated muscle myosins all contain a light chain component that behaves, with respect to desensitised scallop muscle preparations, like the rabbit DTNB light chain. (J. K.-J., E. M. Szentkiralyi and A. G. Szent-Györgyi, manuscript in preparation).

Scallop EDTA light chain and rabbit myosin

Since the rabbit DTNB light chain combined with desensitised scallop myosin, it was natural to enquire whether the scallop EDTA light chain crossreacts with DTNB-treated rabbit myosin. To answer this question, EDTA light chains were radioactively labelled by iodinating their tyrosine residues with ^{125}I (ref. 24) under very mild oxidising conditions. These ^{125}I-labelled light chains function normally with desensitised scallop myosin and bind to DTNB-treated rabbit myosin (about 0.6 mol light chain bound per mol of myosin) but they have no effect on the actin-activated ATPase activity of rabbit myosin when mixed with actin in the presence and absence of calcium, that is, the myosin remains calcium insensitive. Native rabbit myosin binds less than 0.1 mol labelled EDTA light chain per mol myosin, which suggests that the DTNB light chain and EDTA light chain binding sites on this myosin are probably the same or in the same region of the myosin heavy chains. Since the EDTA and DTNB light chains are interchangeable in their respective myosins one might have supposed that these light

Excess EDTA light chains and DTNB light chains were mixed with desensitised myofibrils as described in Table 1. The myofibrillar preparations were subjected to our calcium binding procedure[4], then assayed for ATPase activity[4] and the amount of bound DTNB light chain measured.

chains may have considerable chemical similarity. However, a comparison of their chemical structures as revealed by amino acid analyses and tryptic peptide maps[4,14] indicates no obvious sequence homology. The question of whether these different light chains have highly conserved regions, which may be the heavy chain binding sites, will therefore require more extensive knowledge of their amino acid sequences, which is now under investigation.

Implications

Our knowledge about the role of the DTNB light chain in rabbit myosin is extremely limited. The evidence that rabbit DTNB light chains bind to desensitised scallop myosin and restore calcium sensitivity, that is, they functionally replace the scallop EDTA light chain, is the first indication of a possible functional role of these light chains in rabbit myosin. It may be that these light chains are involved in calcium regulation in rabbit muscle or they may be remnants of a myosin-linked regulatory system that has lost its ability to respond to calcium, due to alterations in the heavy chains. To decide definitely whether vertebrate muscles have a myosin-linked calcium regulatory system similar to that found in molluscan muscles, one must establish directly that these myosins are able to respond to calcium. The available biochemical evidence, however, indicates that purified vertebrate myosins bind rather small amounts of calcium (at 10^{-6} M free calcium) in the presence of physiological levels of free magnesium, and show a calcium insensitive ATPase activity when mixed with pure actin[1,24]. This does not however, exclude the possibility that the myosin binds calcium *in vivo*, since it can be argued that during extraction and purification, this ability has been irreversibly lost. Some support for such a speculation may be provided by recent X-ray diffraction studies[25,26] on stretched frog muscles, which indicate but do not prove, that the myosin cross bridges may be able to respond to changes in the level of free calcium in the muscle. The evidence for and against some type of calcium control by the myosin in vertebrate muscles has been extensively discussed in a recent review of Weber and Murray[27], who conclude that the question of whether there is some type of control mechanism on the myosin in these muscles remains unresolved.

The evidence presented here indicates that the DTNB light chain and EDTA light chain seem to be interchangeable. Even if their overall functions are similar, that is, switching the myosin 'on' in response to the release of calcium during activation, we cannot exclude the possibility that the exact mechanisms involved maybe rather different. For example, in molluscan muscles, calcium released upon activation acts directly on the myosin[2], whereas in rabbit muscle, calcium may act indirectly on the myosin by activating a specific calcium requiring protein kinase[28], known to be able to phosphorylate selectively the DTNB light chain, and thus under *in vivo* conditions this light chain may be phosphorylated which may result in the myosin being switched 'on'[28].

To answer the questions of whether vertebrate myosins contain a regulatory control mechanism and what is the nature of such a mechanism, and to establish the role played by the DTNB light chains, therefore, requires further work specifically with the intact muscle.

I thank H. E. Huxley and A. G. Szent-Györgyi for helpful discussions, and Susan Watt and Neil Smith for technical assistance.

PHYSICAL SCIENCES

Structure of the visible Jovian clouds

DURING the 1972 apparition of Jupiter we studied hydrogen quadrupole line intensities at the centre of the planetary disk, by observing the S(1) lines of the H_2 (3–0) and (4–0) quadrupole bands which are respectively centred at 12268.8 and 15704.01 cm^{-1}. These observations show that the abundance of hydrogen detected at these frequencies is extremely variable because of rapid changes in the structure of the visible clouds, which are confirmed by photographs of the planet.

We observed with the Coudé spectrograph of the 61-cm (24-inch) telescope at the Table Mountain Observatory. Spectra were obtained at 1.6 Å mm^{-1} reciprocal dispersion in the (4–0) band and 2 Å mm^{-1} in the (3–0) band, and were recorded on photographic plates using a single stage S–25 image intensifier tube. The plates were traced with a digital microphotometer and the digital data were reduced to intensity tracings by a computer routine using conventional techniques of photometry. The photometric calibration was checked by measuring, on each tracing, the equivalent widths of several Fraunhofer lines selected to match approximately the intensities and frequencies of the Jovian H_2 lines. The measured intensities of the Fraunhofer lines were systematically low on the tracings and linear least-squares fits were used to correct the measured H_2 lines. The error estimates of one standard deviation (σ) computed from these correction processes are given with the individual measurements.

In Figs 1 and 2 we show the measured equivalent widths of the (3–0)S(1) and (4–0)S(1) hydrogen quadrupole lines as a function of the SYSTEM I longitude. The magnitude of the (4–0)S(1) equivalent widths (EW) varies from 4.2 ± 0.7 to 14.9 ± 2.4 mÅ. This is in contrast to the previously published observations[1,2] which had all centred at about 10 mÅ for the EW and seemed to be independent of both the observer and the terrestrial conditions. The (3–0)S(1) equivalent widths show a similar variation at 34.5 ± 11.3 to 56.9 ± 6 mÅ.

The measurements have been interpreted by constructing a realistic model of the Jovian atmosphere in which all the processes of radiative transfer have been accurately considered[1]. Hydrogen quadrupole lines exhibit the phenomenon of collision narrowing before the more usual pressure broadening occurs, and so it is important that the correct line shape is used in an analysis[3]. We have used the Galatry profile which accurately represents the quadrupole line shape. The nominal model of the Jovian atmosphere proposed by Divine[4], and an H/H_e ratio of 6:1 (ref. 5), which are both consistent with present knowledge, are used as a basis for this analysis.

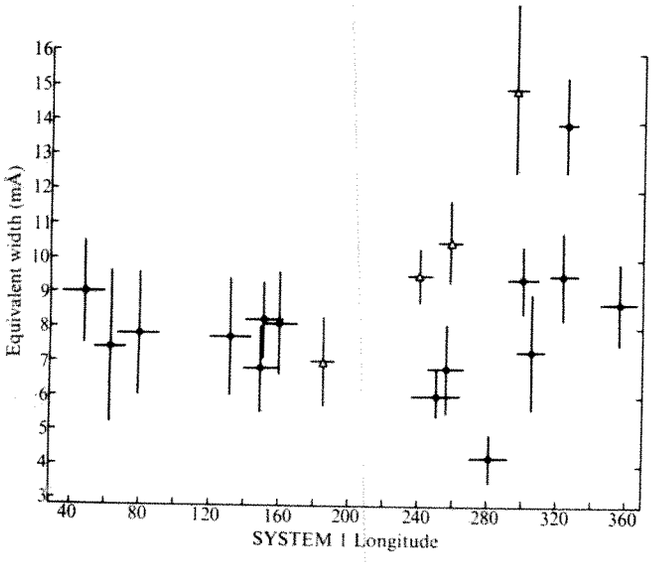

Fig. 1 The variation of the equivalent width of the (4–0)S(1) quadrupole line in the Jupiter spectrum with the SYSTEM I longitude. Solid circles, observations made June 14–30, 1972; triangles, August 17–19, 1972.

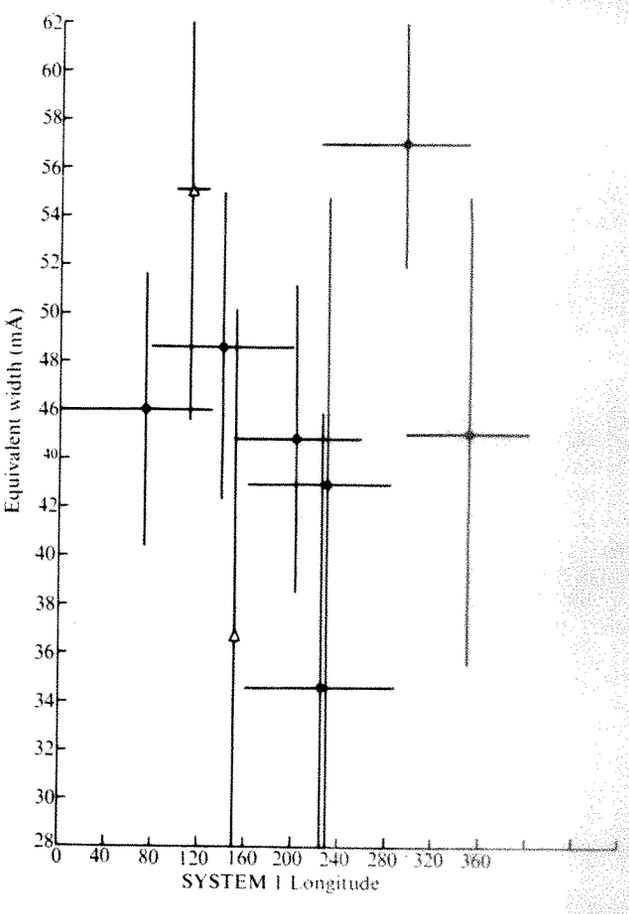

Fig. 2 As Fig. 1 but for the (3–0)S(1) line. Solid circles, June 6–28, 1972; triangles, August 16–18, 1972.

In the equatorial region of Jupiter a structure of two distinct cloud layers is consistent with all observations[5]. The upper cloud may be composed of ammonia crystals, but the composition of the lower layers is unknown[1]. The upper cloud layer is optically thin[1] and we found that it has a negligible effect on the equivalent widths which we observed at the centre of the disk. The lower cloud is optically thick and behaves like a reflecting surface. Consequently, the changes in the derived effective pressure at the level of formation of weak lines, such as the (4–0)S(1) line, will indicate the variability of the top of this dense, lower cloud.

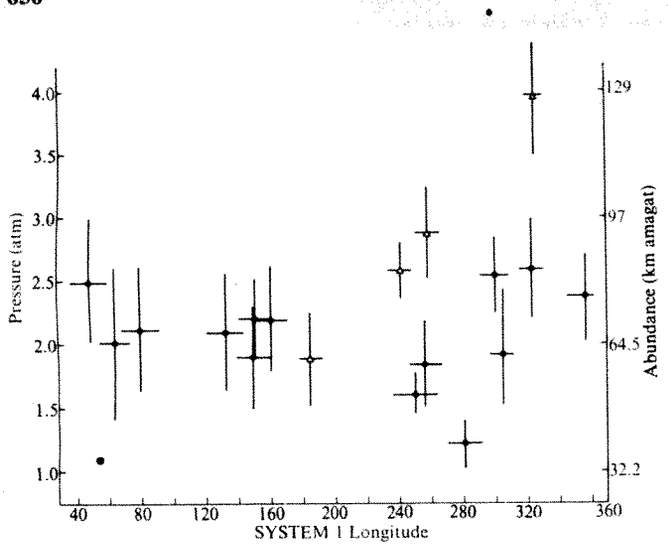

Fig. 3 The variation of the effective pressure at the level of the formation, and the relative abundance of hydrogen, as a function of the SYSTEM I longitude derived from observations of the (4–0)S(1) quadrupole line (Fig. 1).

From the (4–0)S(1) observations we have derived a possible variation of 1.22 ± 0.18 to 4.03 ± 0.93 atm in the effective pressure with a corresponding relative abundance of 39.4 ± 5.9 to 145 ± 30 km amagat (Fig. 3). (1 amagat is the unit of density or volume referring to a gas at 0° C and 1 atm pressure). The analysis of the (3–0)S(1) indicated similar variations of 1.045 ± 0.41 to 2.29 ± 0.51 atmospheres for the effective pressure with the relative abundance varying between 33.85 ± 3.15 and 74.5 ± 16.5 km amagat (Fig. 4). This is a stronger, saturated line which is less sensitive to changes of cloud structure, than the weak (4–0)S(1). These results indicate the futility of quoting a single value for either the effective pressure or the relative abundance derived from spectroscopic observations of a dynamically active planet such as Jupiter.

There are two significant features in the observations illustrated in Figs 1 and 2. First, for the SYSTEM I longitude in the range $160° \leqslant \lambda \leqslant 280°$ the observations carried out during June 1972 show a significant decrease in all of the measured line strengths. For the (4–0)S(1) line this requires the effective pressure at the level of line formation (and therefore at the position of the cloud top) to decrease from $\sim 2 \pm 0.5$ to $\sim 1.25 \pm 0.2$ atm and the hydrogen abundance varies between 68 ± 15–39 ± 13 km amagat. For the (3–0)S(1) line the pressure varies between $\sim 1.6 \pm 0.5 - \sim 1 \pm 0.4$ atm and the abundance

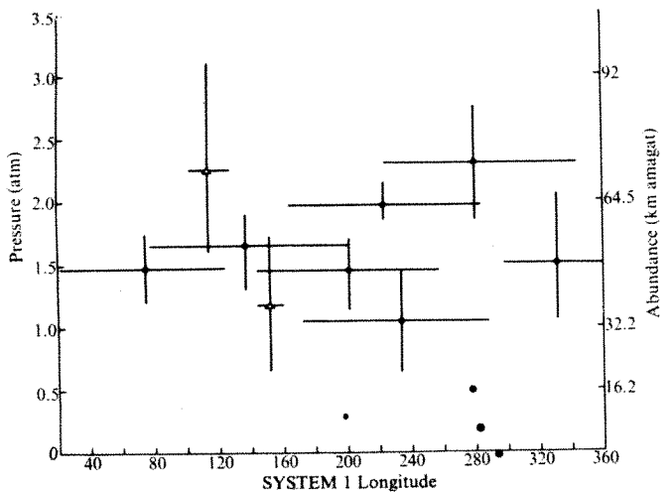

Fig. 4 As Fig. 3 but for the observations of the (3–0)S(1) quadrupole lines (Fig. 2).

varies between $\sim 54 \pm 16 - \sim 33 \pm 13$ km amagat. If these variations are interpreted in terms of changes in the position of the top of the dense, lower cloud, the effective pressure derived from the (4–0)S(1) observations requires this cloud to rise by ~ 25 km from the 2 atm level, during the observational period.

Photographs from the Lowell Observatory International Planetary Patrol, taken at times corresponding to our spectroscopic observations, show significant changes with SYSTEM I longitude of the detailed appearance of the broad equatorial zone. Keay *et al.*[7] have detected temperature variations greater than 40 K in the equatorial zone and have found a strong correlation between temperature and the colours of cloud features in the zones. This increases our confidence in both the detection of fluctuations in the apparent molecular hydrogen abundance and in the interpretations of variations, through a large range of temperature and pressure, in the position of the top of the lower cloud.

With this information we can estimate an upper limit to the vertical velocity of the atmosphere in the neighbourhood of the cloud tops during the observation period. We are assuming that our observations refer to some portion of the planet as it rotates. Hide[6] suggests an upper limit on the vertical velocity W (m s^{-1}) of a fluid element may be derived from the equation

$$W \leqslant U^2 d / f L^2 \qquad (1)$$

where f is the vertical component of rotation (W 10^{-4}s $^{-1}$). As our observations refer to the equational zone we used values of $L \sim 6 \times 10^6$ m for its width and $U \sim 100$ m s^{-1} for a typical horizontal velocity[5]. Inserting a value of $d \sim 25$ km for the height through which the cloud top has moved, equation (1) gives a reasonable estimate of the upward velocity necessary to account for this change in cloud structure:

$$\sim \leqslant 7.5 \text{ cm s}^{-1} \qquad (2)$$

Hide[6] has suggested a value of $\sim \leqslant 10$ cm s^{-1} by observing the changes in colour brought about by the supposed vertical mixing in the atmosphere.

The second significant feature of the observations occurred during August 1972 when an increase in line strength was measured for all lines over the SYSTEM I longitude range of 180–320°. For the (4–0)S(1) line this means that the effective pressure must increase (the level of the lower cloud must decrease) from 1.38 ± 0.77 to 4.43 ± 0.93 atm and the abundance must increase from 61.25 ± 11.75 to 145 ± 30 km amagat. The corresponding changes for the less sensitive (3–0)S(1) line are from approximately 1.18 ± 0.52 to 2.26 ± 0.89 atm and 38.25 ± 16.75 to 73.75 ± 29.25 km amagat. Assuming that we are referring to a single portion of the disk this variation requires the lower cloud to decrease in height by 25 km from ~ 1.38–4.43 atm level during the observational period of two Earth days. From equation (1), the downward velocity, W, will be $\leqslant 7.5$ cm s^{-1}.

This patrol of H_2 quadrupole lines has shown that the abundance of hydrogen and the level of formation of these quadrupole lines is extremely variable. The observations of Keay *et al.*[7] support our conclusions.

Model for the binary X-ray source 2U1700-37

Six X-ray sources have been found which show a periodic variability in their X-ray flux which may indicate orbital motion of a binary system[1].

Two of these sources, Her X-1 and Cen X-3, have pulsed emission with periods respectively of 1.24 s and 4.8 s. From the variation of the pulsed emission period due to the Doppler effect during the orbital motion it is possible to deduce some parameters of the orbit and some physical properties of the system.

A possible model for these X-ray sources is the following: a binary system is made up of a neutron star (perhaps a black hole in the case of Cyg X-1), which is the X-ray source and a star which fills its Roche lobe. The X-ray luminosity is provided by the mass transfer from the star through the internal Lagrangian point and that is accreted by the neutron star.

In the case of Her X-1 and Cen X-3, if the neutron star is rotating and has a strong magnetic field, then the matter is accreted chiefly by the magnetic poles producing hot spots that emit X rays and consequently a pulsed emission. This has been studied in some detail by Davidson and Ostriker[2] and Gnedin and Sunyaev[3].

The evolutionary picture of such a system, with special emphasis on Cen X-3, has been given by Van den Heuvel[4], who has studied the evolution of a close binary system in which a large mass transfer occurs.

The matter transferred from the primary star to the neutron star (X-ray source) is likely to have angular momentum. Therefore a rotating disk will be formed, which gradually spirals inwards as turbulent viscosity transports its angular momentum outward. The spectrum of the radiation emitted by the disk was calculated by Pringle and Rees[5] and Shakura[6].

The model explains reasonably well the properties of Her X-1, Cen X-3, Cyg X-1 and 2U0900–40 (ref. 7) but it fails in the case of 2U1700–37 (see ref. 1).

Here I suggest that in the case of the source 2U1700–37, the primary star, an 07f type star (HD153919, refs 1, 7 and 8) is not filling its Roche lobe and that the matter which is accreted by the neutron star is due to a strong stellar wind from the primary star.

If the primary star fills the Roche lobe, we have a relation between ψ, which is the half angle in the orbital plane subtended by the critical lobe as seen from the X-ray source and the ratio M_s/M_x, where M_s is the mass of the primary star and M_x that of the X-ray source.

I first assume that the orbital inclination angle i is 90°. Then, $\psi/180°$ is the fraction of the period during which the X-ray source is eclipsed. From the data given by Jones *et al.*[1], $\psi \sim 58°$. I note that 2U1700–37 is the source which shows the greatest occultation time, almost one-third of the period.

If $\psi \sim 58°$ the mass ratio is $M_s/M_x \sim 240$.

On the other hand, recent measurements of radial velocity of HD153919 by Van den Heuvel[9] show a nearly sinusoidal variation with an amplitude of 23 km s^{-1}. Since the period is 3.41 d (ref. 1), the mass function is:

$$\frac{M_x \sin^3 i}{(1+M_s/M_x)^2} = 4.3\times10^{-3} M_\odot \qquad (1)$$

With the mass ratio calculated above and $i = 90°$, and using equation (1): $M_x \sim 250 M_\odot$ and $M_s \sim 6\times10^4 M_\odot$, which are very implausible values. The results are even worse when $i < 90°$. I conclude that the primary star does not fill the Roche lobe.

I now assume that the primary star has a strong stellar wind. The primary star is an 07f type and thus has enough ultraviolet radiation to ionise the wind well beyond the neutron star orbit and therefore the accreted material consists mainly of protons and electrons.

I suggest that the occultation of the X-ray source is not only due to the eclipse but also due to the Thompson scattering of the X rays in the extended envelope of the primary star. This seems to be supported by the gradual transition from the visibility to the occulted phase and by the variability on time scales of minutes[1] which can reflect irregularities in the wind, that is partially driven by the X-ray source (J. Aarons, unpublished).

A similar analysis was made by Pringle[10] in the case of Her X-1. In this case, since the primary star is likely to be a FO type, ionisation of the envelope is negligible. There is only a kind of 'Stromgren surface' produced by the soft X rays emitted by the neutron star.

To make some crude calculations of the stellar wind parameters, I assume a constant wind velocity V. In this case, matter conservation requires a wind density $n(r)$, which falls as the inverse square of the distance r from the star, namely,

$$n(r) = \frac{K}{r^2} \qquad (2)$$

where K is a constant to be calculated. I further assume that $i = 90°$.

Then, the optical depth in a given direction θ is

$$\tau(\theta) = \int_0^\infty n(x,\theta)\sigma_T \, dx \qquad (3)$$

where θ is the angle between the vectors from the X-ray source to the observer and from the X-ray source to the centre of the primary star. σ_T is the Thompson cross section (6.65×10^{-25} cm^2) and x is related to r by the equation

$$r^2 = a^2 + x^2 - 2ax\cos\theta \qquad (4)$$

where a is the distance between the X-ray source and the primary star.

From equations (2), (3) and (4)

$$\tau(\theta) = (K\sigma_T/a\sin\theta)(\pi - \theta) \qquad (5)$$

Since the occultation of the X-ray source starts at $\theta \sim 58°$ I assume that $\tau(58°) > 1$. I assume further that at phase 0.5, $\tau \lesssim 1$. Then, from equation (5)

$$1 \gtrsim \frac{K\sigma_T}{a} > 0.4 \qquad (6)$$

Now if $M_x \sim 0.8 M_\odot$ for the neutron star mass, from equation (1) $M_s \sim 12.6\ M_\odot$.

Then, from Kepler's third law

$$G(M_s + M_x)/a^3 = 4\pi^2/P^2 \qquad (7)$$

and with the values obtained above:

$$a \sim 1.6\times10^{12} \text{ cm}. \qquad (8)$$

Therefore, from equations (6) and (8)

$$2.4\times10^{36} \gtrsim K > 9.6\times10^{35} \text{ cm}^{-1} \qquad (9)$$

Since the limits above do not differ by more than a factor three I assume

$$K \sim 2\times10^{36} \text{ cm}^{-1} \qquad (10)$$

to obtain order of magnitude estimates.

From equation (2) the density of the wind at the neutron star orbit, $n(a)$ can be derived. Using the figures given by equations (8) and (10)

$$n(a) \sim 8\times10^{11} \text{ cm}^{-3} \qquad (11)$$

To obtain an X-ray luminosity L_x of about 5×10^{36} erg s^{-1} requires an accretion rate of about $7\times10^{-10} M_\odot$ yr^{-1}. This figure is obtained from the relation

$$L_x \approx (GM_x/R_x)(dM_x/dt) \qquad (12)$$

where I have assumed $R_x \approx 10^6$ cm.

Since the neutron star moves supersonically with respect the wind, the accretion rate is given by

$$dM_x/dt = (4\pi(GM_x)^2/V_R^3)\, n(a)\, m_H \qquad (13)$$

where V_R is the relative velocity between the neutron star and the wind and m_H is the proton mass. From equation (13) and the values calculated before

$$V_R \sim 1{,}640 \text{ km s}^{-1} \qquad (14)$$

Since

$$V_R^2 = V_0^2 + V^2 \quad (15)$$

where $V^2 \sim GM_s/a$ is the neutron star orbital velocity, the wind velocity V is

$$V \sim 1{,}610 \text{ km s}^{-1} \quad (16)$$

On the other hand, the rate of loss of mass dM_s/dt from the primary star due to the wind is

$$dM_s/dt = 4\pi KVm_H \quad (17)$$

and, with the parameters derived above,

$$dM_s/dt \sim 10^{-4} M_\odot \text{ yr}^{-1} \quad (18)$$

The calculated wind velocity and mass loss rate are in good agreement with observational measurements carried out by Morton[11] and Carruthers[12] from the spectra of hot stars, which give a certain credibility to the model.

The data seem to indicate the presence of a secondary minimum at phase 0.5. This can be explained, in principle, in the framework of my model, since the matter is accreted mainly after passing the tail shock[13], increasing locally the optical depth and reducing the X-ray intensity observations are made through the accretion cone near phase 0.5.

If the total angular momentum carried out by the wind is zero, then there should be an increase in the orbital period of the order of 5 s yr^{-1} because of the mass loss calculated above, a result which is very important from the observational point of view. (Aldo Treves called my attention to this point.)

Optical observations (*UBV* photometry) of this system have been made since March 1973 in São Jose dos Campos (São Paulo). The results, with a more detailed analysis of this system, will be presented soon.

Astronomical demonstration of an infrared upconverter

AN upconverter based on a laboratory system[1] developed at the Optical Sciences Center (OSC), University of Arizona, has been used to convert infrared photons from astronomical sources to higher frequency quanta that were detected with a pulse-counting photomultiplier photometer. These observations, made at the Coudé focus of the Steward Observatory 90-inch (229-cm) reflector on Kitt Peak, represent the first successful astronomical demonstration of infrared upconversion, although infrared laser heterodyne radiometry has recently been used to detect the Sun[2] and α Boo[3].

Upconversion is accomplished in an optically nonlinear medium, which in our upconverter is a lithium iodate crystal 5 cm long. Essentially 100% quantum conversion efficiency (QE) was achieved using a 0.6943-μm high peak power ruby laser pump developed at the OSC. This laser seems to be unique among published systems for its efficient generation of TEM_{00}-mode radiation. Details of its design can be found in ref. 4. A 1.064-μm Nd:YAG pumped version of the upconverter yielded a QE of 0.1% (ref. 5). The Nd-YAG pumped upconverter was selected for the astronomical test because it has an infrared spectral bandwidth greater by a factor of 700 and because the effective duty cycle of the Nd-YAG laser is 65 times greater than that of the ruby laser. Therefore, in spite of its lower QE, the Nd-YAG-pumped upconverter is more efficient by a factor of 45 for the detection of thermal astronomical sources.

The astronomical infrared signal at frequency ν_s is phase matched with the pump radiation at frequency ν_p by adjusting the angle of the crystal. The upconverted signal, $\nu_u = \nu_p + \nu_s$, is detected by a pulse counting photometer using a cooled gallium arsenide photomultiplier (RCA C31034). The astronomical source is acquired at the Coudé focus of the 90-inch reflector and directed into the upconverter entrance aperture. The infrared radiation is focused at the appropriate position within the nonlinear crystal. Guiding is accomplished by viewing the image of the source reflected by a dichroic beam splitter to a reticle eyepiece.

Because of the extreme sensitivity of phase matching to angular perturbations, the alignment of the telescope optical axis with the laser pump beam in the nonlinear crystal is extremely critical. We have found it necessary to devote considerable time to this task, and to install auxiliary HeNe alignment lasers to monitor the orientation of optical elements in the system.

The instrument simultaneously upconverts radiation between 3.2 μm and 5.0 μm. This spectral bandwidth of 1.8 μm is the largest ever reported for an upconverter operating in this spectral region[5]. The central wavelength of the operating bandwidth was selected by rotating the lithium iodate crystal about a perpendicular to its optical axis.

During the observations, the laser was pulsed at rates ranging from 0.5 to 4 s^{-1} with a stable pulse width of 2.0 ms and a typical pulse energy of 0.3 J. The Nd:YAG laser is capable of operating at 30 s^{-1}. But we usually operated at 0.5 s^{-1} to permit real-time statistical analysis of the data using an HP-45 portable calculator. Raw data also were printed on paper tape.

The observations were made on the nights of September 8 to September 14, 1973. We attempted to detect the Moon, Mars, α Aur, α Tau, α Ori, Venus, α CMa, ρ Per, NGC1068, α Her, and β Peg. Integrations taken on each object were followed by integrations on the adjacent blank sky. This less-than-optimum detection procedure was used because the telescope was not equipped with a wobbling secondary mirror. The statistical detections are relative to the adjacent sky. An ice dark slide and a glowbar resistor source were also observed. The glowbar data were used to monitor system stability. The ice dark slide data indicated that in practice the thermal background of the detector was definitely less than that due to the telescope and sky.

Multiple statistically significant detections of the Moon, α Tau, α Ori, Venus and α Her were accomplished. Typical data from individual observations with integration times of 0.1 and 0.2 s on September 10, 1973 are summarised in Table 1. These integration times were adequate to yield 2σ (standard deviation) detections of the first four listed sources. Combining data from multiple observations of this type, higher confidence results are obtained.

Table 1 Typical observational data

Object	Signal-to-noise ratio	Integration time* (s)
Moon	2.4	0.10
α Ori	2.2	0.20
α Tau	1.6	0.20
Venus	2.8	0.10
α CMa	0.4	0.20

*Laser pulse of duration 2.0 ms at 0.5 pulse s^{-1}.

Tests showed that a system quantum efficiency (SQE) of approximately 0.001% was attained. This value includes quantum efficiency losses in filters and in the photomultiplier tube. To increase SQE, improvement in the quality of lithium iodate crystals is required, because the currently available material suffers from an absorption which is 0.5 μm wide and centred at 4.3 μm. This absorption results in excess thermal noise from the upconverter when operated at room temperature. We used dielectric interference filters to remove stray flashlamp light from the laser pump beam. The present state of the art should allow better filters, with high transmissivity at 1.064 μm and very low transmissivity at wavelengths below 0.95 μm, to be made. With improvements in the crystal and filter quality, a theoretical SQE of approximately 1.0% could be attained by an upconverter of this type.

We plan to test the upconverter as a device for infrared spectroscopy. This is possible because the upconversion process preserves the frequency coding of the input infrared signal. It will be possible to detect the entire upconverted spectrum simultaneously with a photoemissive image tube because the infrared spectrum is shifted to the 0.83-μm region.

T. R. G. thanks Professor B. O. Seraphin and Dr S. E. Strom for support. We also thank Professor R. J. Weymann, Director of the Steward Observatory, for provision of telescope time. The research was sponsored in part by the Department of the Air Force, Space and Missile Systems Organisation, Los Angeles.

Is the zodiacal light intensity steady?

CONTINUED refinement of data on zodiacal light from OSO–5 (ref. 1) confirms our conclusion[2,3] that the absolute value of both the surface brightness and polarisation of the zodiacal cloud varied by less than 10% over the 4-yr period from January 1969 to January 1973. These results are in stark contrast with the recently published satellite measurements of Levasseur and Blamont[4].

The blue photometer, one of six, which recorded the bulk of the zodiacal light measurements comprised a broadband system with an effective wavelength of 4,180 Å, an 11° circular field of view and a fixed polaroid. The photometer viewed along the anti-sail spin axis of the satellite which rotated once every 2 s. The spin axis was held in a plane whose normal was directed at the Sun. Its movement within this plane varied from 0.1° to 1.0° d^{-1}.

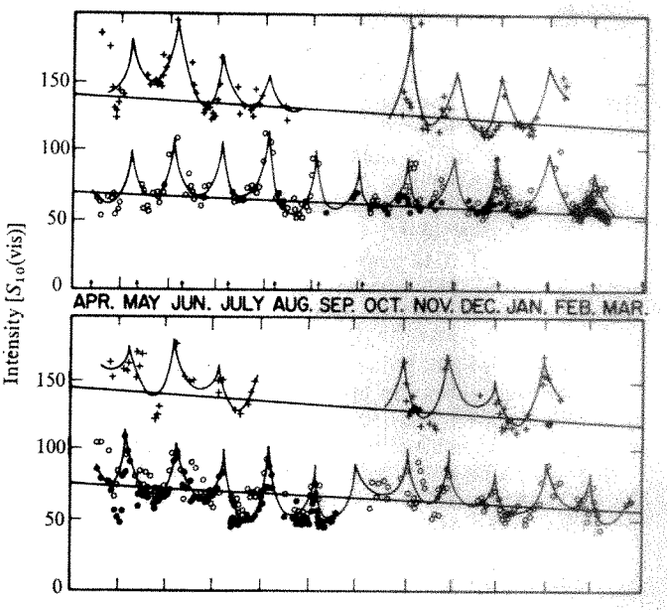

Fig. 1 Zodiacal light data of Levasseur and Blamont (Fig. 4 of ref. 4).Mean value of the intensity for eight directions: top graph $\epsilon<0$; +, ecliptic plane; ○, $+45°\beta$; ●, south pole. Bottom graph $\epsilon>0$; +, ecliptic plane; ○, $\pm45°\beta$; ●, north pole.

Measurements were then made at $\varepsilon=90°$ and varying ecliptic latitudes, usually with $\beta=\pm35°$. Readings were taken at the rate of three a second for 15 min of each 96-min orbit with a night-time look height of 400 km or higher. There were 15 orbits a day for most of four years. Usually, 1,880 readings or 5 min of data were reduced to determine the brightness and polarisation for that night. So detection of changes down to a time scale of hours was possible through the four year period with the following exceptions.

The previously published results[2,3] did not include readings when: (1) the Moon was within 50° of the field of view (one week out of four); (2) a first magnitude object was on the edge of the field of view (seldom); (3) the galactic latitude was less than 30° (four out of 12 New Moon periods). Given these exclusions an absolute calibration of 10% over four years was made. The relative calibration precision over any New Moon period was found to be 5% or less.

The effect on the Moon on telescope 3 was most evident during either first or third quarter depending on the orientation of the spin axis. At these times the Moon could be within 50° of the spin axis. The airglow telescopes in the opposite sail direction were severely hampered any time the Moon was above the satellite horizon. This was because protruding parts of the spacecraft at times allowed reflected moonlight to fall within 50° of the spin axis. (Nightglow measurements were not made with the Moon up.)

The six-parameter least-squares fit made in reducing a 5-min data interval proved of great value in detecting contamination light scattering into the optics from the Moon, moonlight reflected from the Earth, and bright stars and planets near the field. In such cases a considerable variation of intensity at the spin rate as well as at the polaroid frequency, which was twice the spin rate, was seen. Without such a check it would have been more difficult to avoid periodic variations with a lunar period in the data.

So the effects of the Moon may be appreciable any time it is above satellite horizon. The time of maximum effect depends on the particular geometry involved. We have

placed a periodic variation typical of reflections, with lunar frequency, over the data of Levasseur and Blamont (Fig. 1). No attempt at an exact fit to the data has been made, and much of the Full Moon data had already been removed. Nevertheless the chief peaks in the data of Levasseur and Blamont fall between first quarter and Full Moon, except for the initial peak which comes within a few days of launch. Further the New Moon data are quite free of the fluctuations otherwise seen, and a straight line drawn through their New Moon data has a consistent slope in all four sets of data indicating photometer degradation of some $20 s_{10}$[vis] per year in excess of the calibrations that were used to reduce the data.

Data with galactic latitude less than $\pm 30°$ have also now been studied. For data closer to the galactic plane, the absolute calibration errors increased from 10% to 30% due to increased problems of star background and diffuse galactic light subtraction. The relative calibration precision over any New Moon period increased from 5% to 10%. Within these limits again no variations were found in either the brightness or polarisation of the zodiacal light.

A relative variation of 10% or less was observed during the periods April 15 to 29, 1971, and November 2 to 16, 1971. These results are in direct conflict with the satellite measurements of Levasseur and Blamont[4] who have recently reported enhancements of 50% on April 21, 1971, with a half enhancement lasting 4 d, and a 100% enhancement on November 7, 1971, with a half enhancement of 6 d. The enhancements were attributed to debris of comets 1961-I and Biela.

Figure 2 shows our results for surface brightness and polarisation during these times. The absolute intensities during the April period are higher than the November period because the ecliptic latitude is lower. The scatter in the data is caused by the difficulties in subtracting out the star background near the galactic plane. It is typical of our relative calibration precision of 10% at low galactic latitudes. From April 15 to 29, 1971, our measurements were taken at $\varepsilon = E90°$, $\beta = 10° \pm 2°$. For comparison, the results of Levasseur and Blamont report an increase of 50% at $\varepsilon = E90°$, $\beta = 0°$, a 50% increase at $\varepsilon = W90°$, $\beta = N90°$, and a 50% increase at $\varepsilon = W90°$, $\beta = N45°$. From November 2 to 16, 1971, our measurements were taken at $\varepsilon = 90°$, $\beta = N30° \pm 2°$. During this period Levasseur and Blamont report an increase of 100% at $\varepsilon = E90°$, $\beta = N0° - 30°$, and no increase in the $\varepsilon = W90°$, directions. In addition, none of the other sizable variations prevalent in the data of Levasseur and Blamont from April 1971 until March 1972 have been found in our data covering this period.

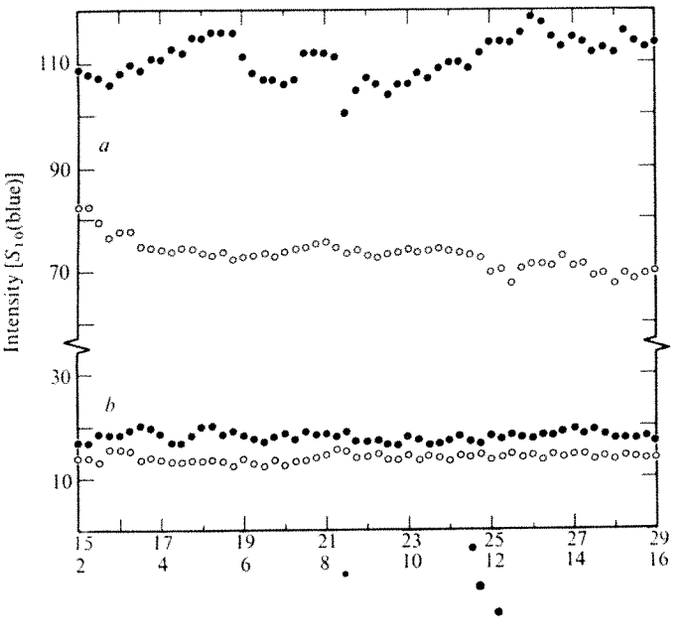

Fig. 2 The brightness (*a*) and polarised intensity (*b*) of the zodiacal light as measured by OSO-V; ●, April 15 to 29, 1971; $\varepsilon = 90°$; $\beta = S10° \pm 2$. ○, November 2 to 16, 1971; $\varepsilon = 90°$; $\beta = N30° \pm 2$. Absolute calibration precision = 30%, relative calibration precision = 10%.

On two occasions, the Lagrangian points L4 and L5 of the Earth–Moon system passed within 2° of the centre of the field of view of our blue zodiacal light telescope. These events took place on January 29, February 7, 1971, and June 25, July 6, 1971. No change in either the intensity or polarisation to the limiting accuracy of the experiment (10%) were observed. This sets a full field upper limit of $10 s_{10}$ (blue) for any change in surface brightness and $2 s_{10}$ (blue) for any change in polarisation due to scattering from dust accrued at these points.

We believe the zodiacal cloud to be a smooth, regular feature of the Solar System as one might expect from a steady influx of particles from the continual breakup taking place in the asteroid belt. There is no evidence for a cloud, with intensity fluctuations of a factor of two, composed of an interwoven maze of comet trails. No variations in intensity or polarisation greater than the limit of accuracy of the experiment—usually 10% arising from comets, solar activity, lunar phase or other events in the Solar System—were observed.

f Gravity and gravitational singularities

Trautman has postulated[1] that the usual space–time singularity occurring in classical cosmological models and in the gravitational collapse of massive objects could be averted if intrinsic spin effects are incorporated into general relativity by adding torsion terms to the usual Einstein field equations, that is through the Einstein–Cartan theory. Invoking a primordial magnetic field for aligning all the individual nuclear spins he shows that his universe consisting of 10^{80} aligned neutrons collapses to a minimum radius of the order of 1 cm with a corresponding matter density of 10^{55} g cm^{-3}.

Salam *et al.*[2] have investigated the effect of taking *f* gravity into account in Trautman's model. They consequently obtain profound changes in the numerical values of the parameters, the minimum radius of the Trautman universe now being of the order of 10^{13} cm rather than 1 cm, implying that spin-aligned hadronic matter will not collapse to densities higher than 10^{17} g cm^{-3} — only two or three orders of magnitude higher than that of nuclear matter. But the perfect spin alignment necessary for these results still remains difficult to realise. We now suggest a possible way to avoid this difficulty and still retain all the results.

Two of us have shown[3] that perhaps the easiest and most natural way to include the short range of *f* gravity (mediated by massive spin 2^+ *f* mesons) into Einstein's field equations was to reinterpret the so-called 'cosmological' constant

terms of the inverse Compton length of the f meson

$$\Lambda \simeq \left(\frac{m_f c}{\hbar}\right)^2 \quad (1)$$

m_f being the mass of the f meson.

In the massless (infinitive range) gravity field of conventional general relativity mediated by massless gravitons, $\Lambda = 0$.

Now the usual Friedmann equation with Λ, for a zero pressure Einstein–de Sitter universe is

$$\dot{R}^2 = \left(\frac{8}{3}\right)\pi G\rho R^2 - \left(\frac{2}{3}\right)\Lambda c^2 R^2 \quad (2)$$

with $M = \left(\frac{4}{3}\right)\pi R^3\rho$, being the total mass of the 10^{80} baryons in the Universe. Using $\dot{R} = 0$ at $t = 0$, gives

$$R(0) = \left(\frac{3GM}{\Lambda c^2}\right)^{1/3} \quad (3)$$

Λ is defined as in equation (1), where $m_f \simeq 1{,}500$ MeV. Substitution in equation (3) yields $R(0) \simeq 1$ cm and the corresponding density of matter is $\rho = \left(\frac{\Lambda c^2}{4G}\right) \simeq 10^{55}$ g cm^{-3}. These values are the same as in Trautman's model. It turns out that the Λ term in equation (2) is of the same order of magnitude as the torsion term in Trautman's model. In both cases these additional terms (torsion term in Trautman's, Λ term in ours) in the Friedmann equation are the ones which avert the singularity. For $\Lambda = 0$ (the massless gravity field of infinite range), we recover the old singularity. If we invoke f gravity (and especially as matter in a superdense collapsed state is predominantly composed of hadrons it is reasonable to consider the gravitational interaction between them at short range to be due to exchange of massive f mesons), we must necessarily use the corresponding constant G_f. Therefore, replacing the Newtonian constant G by G_f, the value of which has been estimated[8] to be of the order of $10^{39}G$, we obtain $R(0) \simeq 10^{13}$ cm and the corresponding matter density as $\simeq 10^{17}$ g cm^{-3}. These results are the same as obtained by Salam *et al.* We note in particular that in our formulation the difficult hurdle of finding a suitable mechanism for the alignment of all hadron spins is not encountered. We can understand this result by noting that the Hawking–Penrose[4] singularity theorems for the Einstein field equations $G_{\mu\nu} + \Lambda g_{\mu\nu} = \kappa T_{\mu\nu}$, do not necessarily hold if the cosmological constant Λ is positive, which is implied by our definition in equation (1). Indeed it is remarked in ref. 2 that for all spins aligned in the same direction, the effective spin–spin interaction term in the Lagrangian for the Einstein–Cartan theory which forms the essence of Trautman's torsion term, can be regarded as being of the form $L = -(-g)^{\frac{1}{2}}\,\Lambda_{eff}(x)$, where $\Lambda_{eff}(x)$ is a positive effective cosmological contribution to the Lagrangian. Moreover, as we pointed out earlier, the Λ term we have used in the Friedmann equation is of the same magnitude as Trautman's torsion term.

It is interesting to note that by using G_f instead of G, the absurdly large density $c^5/G^2\hbar \simeq 10^{94}$ g cm^{-3} at which quantum effects of the gravitational field are expected to become important is scaled down to $\simeq 10^{17}$ g cm^{-3}. The corresponding Planck length $(\hbar G/c^3)^{\frac{1}{2}} \simeq 10^{-33}$ cm, at which quantum fluctuations in the space-time curvature are supposed to become significant[5–7], is then scaled up to $\simeq 10^{-14}$ cm. This probably indicates that the quantum effects in f gravity become important during much earlier stages in the collapse, when the density is $\simeq 10^{17}$ g cm^{-3}.

Trends in the vertical distribution of ozone over Australia

Komhyr *et al.*[1] reported predominantly positive trends in total ozone content over several stations in the 1960s (see also refs 2–4). Here I report the first detailed estimates of trends in the vertical distribution of ozone and discuss some possible causes.

Soundings of the vertical distribution of ozone have been made on a regular weekly basis at Aspendale, Australia (38.0°S, 145.1°E) since June 1965 (ref. 5). Some 432 soundings reached above the 18.1 mbar (27 km) level during the first 8 yr of the programme. Data from these soundings have been corrected to agree with the total amount in a vertical column measured with a Dobson spectrophotometer, by the method[6] in which the ozone concentration above balloon burst is extrapolated along a line of constant mixing ratio for burst heights above the 18.1 mbar level. Extrapolated data are used to calculate the correction factors, but are excluded from the mean data used in trend analysis.

Estimated trends are based on a least squares linear regression against time of 48 successive deviations of 2-month mean ozone partial pressures (from the 8-yr means for the corresponding months) for each of 36 standard levels from 1,000 mbar to 10 mbar. The results are shown in Fig. 1.

Outstanding features are the statistically significant decreases in ozone content—of the free troposphere (chance probability $P < 1\%$ between the 700 and 450 mbar levels), and around the level of the primary ozone maximum ($P << 0.1\%$ at 35 mbar)—and significant increases in ozone content above the 17 mbar level ($P < 0.1\%$ at 12 mbar).

Over the same period of 8 yr the total ozone content as measured by the Dobson spectrophotometer at Aspendale shows an estimated trend of (-3.1 ± 1.1) % per decade.

Table 1 shows these estimated trends in the total ozone content, in the integrated ozone amounts in 10 km thick layers up to 30 km, and in the integrated amount above 30 km (the difference in the trends in the total amount and in the amount below 30 km), all in units of thickness of ozone (reduced to STP) per decade.

Table 1 Ozone trend estimates in various layers of the atmosphere in units of reduced thickness of ozone per decade (data June 1965 to May 1973 inclusive)

Layer (km)	Trend (10^{-3} atm cm per decade)
0 – ∞	−9.9
0 – 10	−2.7
10 – 20	−6.7
20 – 30	−11.2
Above 30	+10.7

The mean total ozone content during the 8-yr period is 0.318 atm cm, and the integrated amount above 30 km is 0.058 atm cm. Thus the mean increase above the 30 km

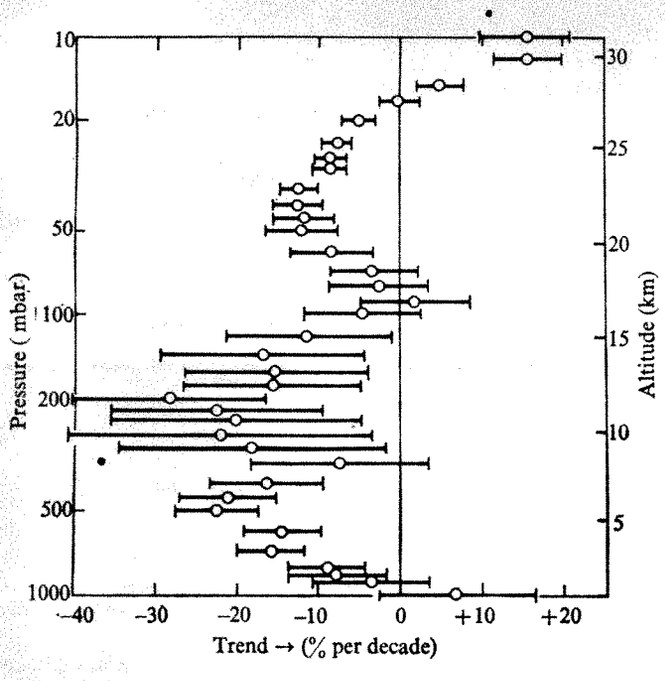

Fig. 1 Estimated trend (% per decade) of ozone partial pressures at 36 standard levels over Aspendale (38°S, 145°E) for 1965–73. Standard errors of the estimates are indicated.

level is 18.5% per decade, in good agreement with the direct trend estimate of $(+15.3 \pm 5.6)\%$ per decade at the 10 mbar (31.1 km) level (Fig. 1).

Trends in the vertical distribution of ozone of such magnitude and statistical significance are of interest in relation to questions of climatic change, global monitoring and pollution, and ozone photochemistry and interacting circulation processes.

Mean annual cycles of ozone partial pressure (nbar) at the 10 mbar and 40 mbar levels are shown in Fig. 2 for Aspendale, with comparable data for Thalwil, Switzerland[6] (47°N) and Boulder/Albuquerque[6,7] (37½°N). As well as the interhemispheric comparison (which will be discussed elsewhere), these curves confirm that the ozone concentration at the 10 mbar level is dominated by photochemistry (maxima in summer) whereas that at 40 mbar is dominated by transport processes (maxima in the late winter and spring).

One might reasonably suggest that the trends at and above the 10 mbar level are due to some process affecting the ozone photochemistry, such as some solar influence or a circulation-induced change in the photochemical process such as a change in the upward flux of NO_x. The trends below the 17 mbar level are most plausibly related to a change in circulation which either reduces the downward flux of ozone from the region of photochemical production or else increases the concentration or flux of some chemical species which destroys ozone in the lower layers. Perhaps the simplest hypothesis is to postulate increased static or dynamic stability at about the 17 mbar level.

Trend analyses of the deviations of 96 consecutive monthly mean temperatures from the 8-yr means for the corresponding months at Laverton, Victoria (the nearest aerological station, some 35 km north-west from Aspendale) show no statistically significant trends at the 10, 15, 50, 100 or 200 mbar levels. Similarly there are no significant trends in the temperature gradients between the 10 and 15, 15 and 50, 50 and 100 or 100 and 200 mbar levels which might have indicated a change in static stability. Estimation of possible trends in the dynamic stability is beyond the scope of the present work, but I note that the available wind data became increasingly inadequate above the 50 mbar level. Any such trend has not resulted in a significant change in the mean temperature or temperature gradient at any of the levels listed above.

Trend analyses of two parameters of the general circulation, the mean latitude of the high pressure belt[8] and the abbreviated southern oscillation index[9], indicate such small trends that they are clearly not related to the observed trends in ozone.

Long term trends in the ozone content above the 30 km level have been tentatively reported[10] and related to the solar cycle. Paetzold *et al.*[11] reported a significant positive correlation between ozone content in the region 20–30 km and sunspot number. They suggest a direct causal link with variations in solar radiation at about 210 μm with no significant phase lag. But the Aspendale data, which span the sunspot maximum of 1968–69, show no evidence of a change in the sign of the trend.

The observed decrease in ozone content below the 17 mbar level could be due to *in situ* destruction by contaminants such as volcanic dust or NO produced by nuclear bomb tests[12]. There is, however, little to support this from the ozone record following the Mt Agung eruption in 1963 (refs 3 and 13) or the resumption of atmospheric bomb testing in 1962–63 (ref. 3), unless the time scale for such effects is so long that no statistically significant departures from normal were to be expected in 1963 or 1964 (ref. 14).

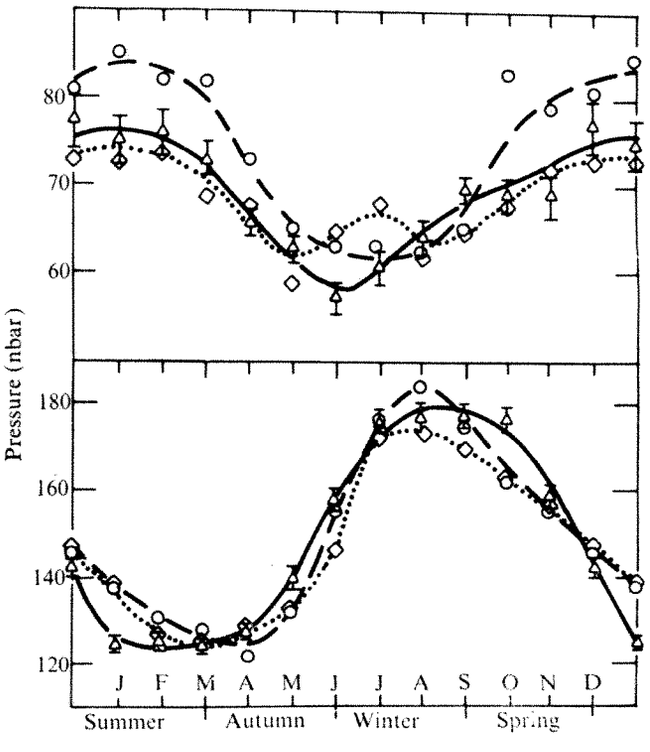

Fig. 2 Mean annual cycle of ozone partial pressures (nbar) at the 10 mbar level (upper diagram) and at the 40 mbar level (lower diagram) for: △, Aspendale (38°S); ○, Boulder/Albuquerque (37½°N); ◇, Thalwil (47°N). Standard errors are shown for the Aspendale results.

I conclude that the cause of the observed ozone trends is at present an open question. These trends are large enough to warrant careful attention in relation to questions of climatic change, global monitoring and ozone photochemistry. More data are needed from more stations and over longer time intervals, and the various possible explanations must be exhaustively tested by all available means.

Radiocarbon and tritium evidence for direct rain recharge to ground waters in the northern Kalahari

THE Kalahari, a flat and sand-covered region of more than 600,000 km² (Fig. 1), has long been classified as a desert because of the virtual absence of surface waters in the form of springs or perennial rivers. The only exception is the inland drainage system in the north, the Okavango delta and Makgadigadi salt pan, which are fed successively by rainwater which drains from the remote highlands of Angola through the Okavango river.

Many investigators[1-6] have subscribed to the view that a sand over-burden exceeding an estimated 6 m would effectively prevent infiltrating rainwater from reaching phreatic water tables. All rainwater retained in the sand would thus be lost by capillary rise and evapotranspiration, chiefly during the dry season. In the area under study, with varying sand cover thickness, the possibility of direct rain recharge was consequently ignored in economic surveys and the ground waters considered to be fossil relics from earlier, much wetter periods.

Table 1 ^{14}C and tritium in phreatic ground water of the northern sand-covered Kalahari

No.	Well	^{14}C (% m.c.)	Tritium (TU)

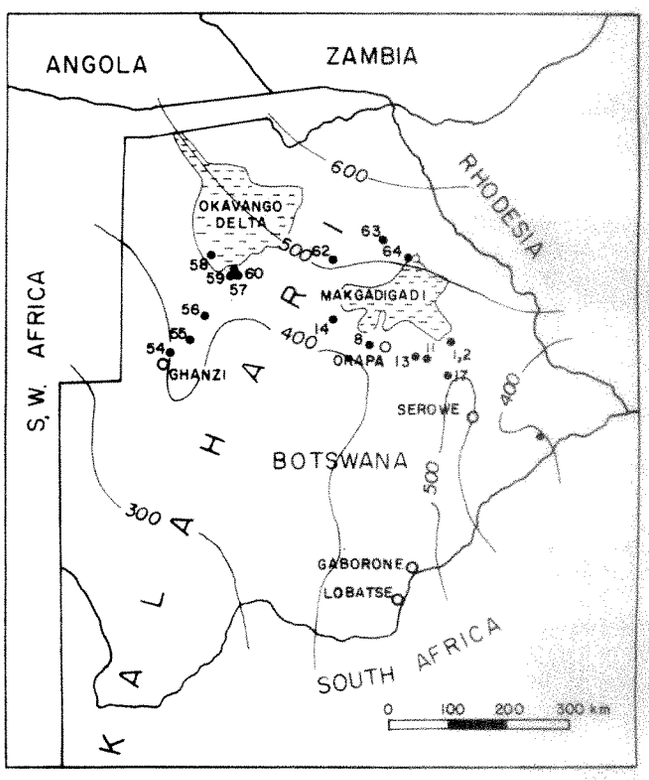

Fig. 1. Sample locations referred to in Table 1.

Recent investigations we have carried out in collaboration with the Geological Survey of Botswana have shown that rain recharge does occur in areas covered with sand. A controlling factor is the annual amount of precipitation, which averages 450 mm in the north, gradually decreasing to 250 mm in the south. In addition, the seasonal variability of annual rainfall with the occasional high rainfall outliers (such as the seasons of 1966–67 and 1973–74) is of extreme importance for recharge.

We sampled several phreatic wells in the northern Kalahari and the environmental ^{14}C ($t_{1/2}$=5,730 yr) and tritium ($t_{1/2}$=

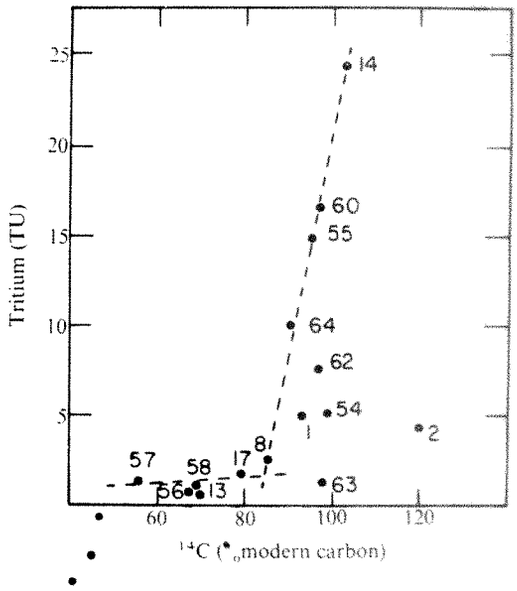

Fig. 2. Radiocarbon-tritium correlation. Samples with values greater than 85% modern carbon radiocarbon and greater than 2 TU of tritium contain a post-nuclear bomb component. Dashed lines, theoretical trends for pre-bomb and post-bomb waters.

12.3 yr) data are reported here (Table 1 and Fig. 1).

Since 1952 nuclear bomb tests have increased the radiocarbon content of atmospheric carbon dioxide above the pre-bomb level of 100% modern carbon (m.c.). Levels in the Southern Hemisphere reached a peak of 165% m.c. in 1963 and decreased to 145% m.c. in 1972 (ref. 7). Biogenic carbon dioxide is dissolved in infiltrating ground water and then reacts with lime free of ^{14}C to produce dissolved bicarbonate. Carbon dioxide at 100% m.c. will produce bicarbonate containing 60 to 90% m.c. through this dilution, with an average of about 85% m.c. (ref. 8). All values above 85% m.c. in Table 1 can therefore be regarded as containing post-bomb recharge, most clearly indicated in the first two cases at 106 and 120% m.c.

The average annual value of tritium in continental rains before the inception of bomb tests in 1952 is estimated at around 5 TU (tritium units). Southern African values reached 60 TU in 1963 and have decreased to about 25 TU at present (ref. 9 and unpublished data). Undiluted recharge at 5 TU in 1952 has decayed to less than 2 TU at present. Therefore, all waters with more than 2 TU must contain a component of recharge from the last 20 yr.

The observations (Table 1 and Fig. 2) corroborate the basic assumptions in the analysis of the tritium and ^{14}C results. The two lines, which tend to define the limits of the results in the pre-bomb and post-bomb eras, intersect at about 2 TU and 85% m.c. The low tritium concentration values to the right of the limit line may indicate different responses to atmospheric bomb tritium and ^{14}C increases. The shallow (1 m) sample no. 2 might present a special case in that roots tapping the water enhance downward transport of ^{14}C.

Ages greater than 20 yr are therefore indicated by values below 85% m.c. The lack of secure theoretical foundations does not permit accurate ^{14}C age calculations. But with an initial value of 85% m.c. waters with 50% m.c. would still be more recent than one ^{14}C half life. Waters in the range of 50 to 85% m.c. may therefore be regarded as having ages from a few hundred to a few thousand years at most, which implies that they are hydrologically active.

Both the radiocarbon and tritium data lead to the unambiguous conclusion that ground waters in the northern Kalahari are directly, and in some cases rapidly, recharged by rain.

Balanced exploitation could make room for additional recharge which is partly lost to evapotranspiration from the often shallow water tables. Even at values of rainwater infiltration as low as 5%, this could still constitute a significant managed ground water supply.

Geomorphology of Siluro-Devonian alluvial plains

The Anglo–Welsh outcrop of the Lower Old Red Sandstone (Siluro–Devonian) reaches approximately 2,000 m in thickness and is largely alluvial[1], consisting of long sequences of fining upwards cyclothems[2]. The fine grade (floodplain) members of the cyclothems commonly include one or more pedogenic carbonate units which are evident in the vertical profile[3–6]. The carbonates seem to represent episodes of soil formation, each of which lasted for about 10^4 yr. Well horizonated palaeosols indicate periods of prolonged weathering, which implies that the alluvial plains on which they were formed remained unflooded for long periods. This could have arisen either because rivers shifted about on the plains, or because of a cyclical river dissection–aggradation coupled with lateral movements. The distribution of Quaternary calcretes[7] suggests that the climate was hot (mean annual temperature 16–20° C) with a low seasonal rainfall (mean annual precipitation 100–500 mm). This is supported by palaeomagnetic results, which indicate a low (southerly) latitude for the Anglo–Welsh area[8].

Four plausible models are considered, which give sequences consistent with known river behaviour and which are applicable to alluvial sequences in the Lower Old Red Sandstone and similar formations.

Model A. Each river, by step-like channel movements combs systematically from side to side of an alluvial cone, in the manner of the Kosi[9] and Indus[10,11]. Soil formation near one side is most intense when the river is active at the opposite side. The resulting palaeosols are discrete, laterally extensive, but non-uniform sheets, each equivalent in time to numerous channel sand-bodies (coarse grade cyclothem members). Provided that the distance moved by the active channel at each step exceeds the width of the channel belt (if braided) or meander belt (if sinuous), vertical profiles show cyclothems with a range of numbers of palaeosols. Fine grade members with no palaeosols result from the erosional emplacement of channel deposits. Control in this model is autocyclic[12], that is, intrinsic to the fluvial regime, and external factors such as climatic change, eustasy and tectonism need not be involved.

Model B. Rivers periodically shift major lengths of their channels by large, almost random distances. This is described as avulsion. It also has an autocyclic control and is well known from modern streams[13,14]. Because the effective zone of the river is laterally restricted, soils can form at sites more distant from the stream. The repeated avulsion gives an alluvial sequence in which palaeosols repeatedly split around bodies of floodplain sediment. The pedogenic carbonates in this model are partly interconnected, either fusing with other palaeosols or having erosional or feather-edge margins. Provided that the lateral distance moved by a river at each avulsion substantially exceeds the width of the channel belt or meander belt, vertical profiles through the alluvium will show cyclothems with contrasted numbers of palaeosols. Each palaeosol is the time equivalent of a number of coarse grade members formed elsewhere. Erosional emplacement of coarse grade members partly explains cyclothems which have no palaeosols. Some floodplain sequences, however, may never have undergone pedogenesis.

Model C. Cyclical river dissection–aggradation occurs because of climatic fluctuations between more and less arid conditions. Following inferred events in the Australian Riverine Plain[15,16], the Lake Torrens Piedmont[17], the Algerian Aurès Mountains[18], and the valley of the Rio Grande[19–22], a shift into relative aridity causes a reduction in the discharge of the river, which leads to channel dissection. The diminished stream lies entrenched in a shallow, possibly terraced, valley, and pedogenesis begins on the terraces and the interfluvial plains, which are no longer flooded by the river. With a climatic amelioration, river discharge again increases and valley filling begins. Soil formation is halted, first on the terraces, and then on the interfluvial plains, as floods become more frequent and widespread.

As soon as the valleys are fully aggraded, the rivers can move laterally by avulsion until the next climatic reversal, by which time they will be in new positions. The alluvial piles thus created have discrete pedogenic carbonates of fairly uniform lateral development, largely embedded in floodplain deposits. Provided that the rivers shift laterally by substantial amounts during each climatic amelioration, the cyclothems show a range of numbers of palaeosols in vertical profile. Fine grade members without palaeosols are largely a result of the erosional emplacement of channel deposits. The main control in this model is allocyclic[12], that is, external to the river regime, though autocyclic avulsion is at times prominent.

Model D. This model is similar to model C but uses a change of base level as the allocyclic control, in combination with avulsion. A fall of the base level causes river entrenchment and promotes soil formation on the exposed interfluvial plains, whereas a rise leads to valley aggradation and river avulsion, and stops pedogenesis in interfluvial areas. For example, rivers crossing the Gulf Coastal Plain to the Gulf of Mexico became entrenched during the Pleistocene glaciations, so that soils formed on the interfluvial plains, but during interglacial periods they aggraded their valleys[23]. The cyclothems and alluvial structure of model D are similar to those of model C. In vertical profile the cyclothems may again contain more than one palaeosol. The erosive emplacement of coarse grade members explains the absence of palaeosols from some cyclothems. model D remains plausible, however, only if the change of base level is less than approximately the channel depth. With bigger ranges, the theoretical coarse grade members are inconsistent with field data, to judge from modern rivers[14]: they are much thicker than the 2–3 m typical of lateral deposits and coarse grade members in the Lower Old Red Sandstone[5], and they are multistorey, with evidence of a change from a braided to a meandering channel pattern during aggradation.

With models A and B, the Siluro–Devonian alluvial plains comprise, at any instant, constructionally active and inactive zones in juxtaposition, with relief arising from alluvial ridges either occupied or recently abandoned by streams. Models C and D provide a more complex picture, though again of juxtaposed active and inactive zones. At one extreme of the controlling cycle, the plains comprise shallow valleys with active rivers and broad interfluvial areas devoid of major drainage. Relief arises from alluvial ridges, active and abandoned, and from valley sides and perhaps river terraces. At the other extreme, the plains are less diverse geomorphologically, with relief provided as in models A and B.

These models provide three alternative possible gross structures for the alluvial sequence. They differ in the three-dimensional fit of the cyclothems, and in the shape, development, and degree of interconnection of the included palaeosols. The structures are all plausible in terms of the essentially one-dimensional vertical profiles observed in the Lower Old Red Sandstone. Finer distinctions demand that an adequate number of cyclothems can be confidently traced laterally over distances of the order of kilometres. This will be possible in the Anglo–Welsh area only through extensive, and expensive, shallow borings. Nonetheless, model D may perhaps be preferred. Recent work shows that the Temeside Shales (?late Silurian), near the base of the Lower Old Red Sandstone, possess palaeosols. As these beds resemble intertidal deposits[24], base level fluctuations could explain the episodes of pedogenesis.

Orogenic zones in central Australia: intraplate tectonics?

THE plate tectonics model[1,2] has been successful in explaining the orogenic features of the ocean basins and continents associated with the dispersal of Pangaea in post-Triassic time. Dewey and Bird[3] extended these concepts, suggesting that there is a unique relationship between orogenesis and plate-margin tectonism, and various authors have, accordingly, interpreted certain Precambrian and Palaeozoic orogenic zones or 'mobile belts' as plate sutures[4,5]. We argue here that plate-margin tectonism is only one of several possible conditions for the development of an orogenic belt. We suggest that the plate tectonic model of orogenesis needs to be extended and modified, and this suggestion is discussed for Gondwanide Australia. Recent attempts to impose a rift (aulacogene)[6] or subduction[7] model for orogenesis in central Australia are confounded by the observed geological and geophysical facts pertinent to this region.

Three zones of major thrust faulting in crystalline basement rocks have been recognised in central Australia. They bound the Ngalia and Amadeus Basins (Fig. 1) and are characterised by steep gravity gradients[8]. The Amadeus and Ngalia Basins are intracratonic depressions containing latitudinally folded and thrusted Proterozoic and Palaeozoic sedimentary cover rocks[9,10]. The Musgrave Block, south of the Amadeus Basin, was deformed about 600 million years (Myr) ago during the 'Petermann Ranges Orogeny'[11] when the Woodroffe Thrust developed in the basement south of the basin. The Arunta basement complex was deformed during the 'Alice Springs Orogeny'[11] in late Devonian or early Carboniferous time[12]. While the basement rocks of the northern margins of the Amadeus and Ngalia Basins underwent major thrusting and retrograde metamorphism, the overlying Proterozoic cover rocks deformed independently above a decollement horizon[9].

Thick syntectonic molasse-type sediments are associated with the Alice Springs and Petermann Ranges events. Unconformities in the cover sediments, and the thickening and coarsening of facies against the northern margin of the Amadeus Basin[13] indicate that the crystalline basement was

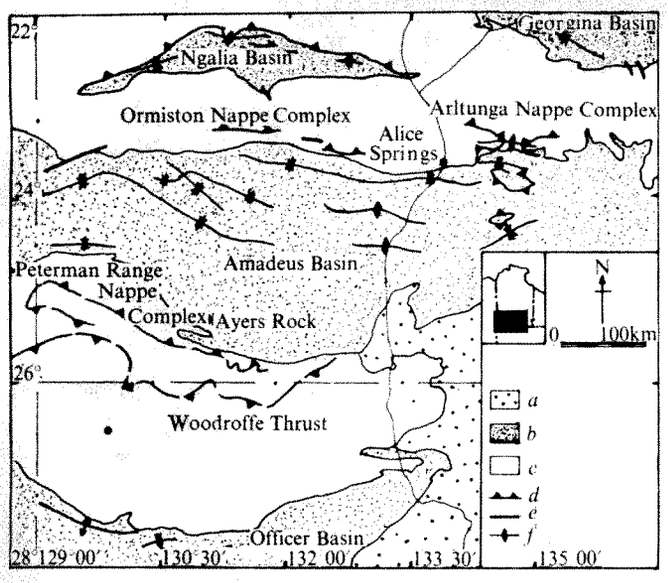

Fig. 1 The location and major structural features of the intracratonic basins and deformed basement zones of central Australia. *a*, Mesozoic strata; *b*, Proterozoic and Palaeozoic cover; *c*, older Precambrian basement rocks; *d*, thrust fault, indicating upper plate; *e*, fault; *f*, major fold.

uplifted at various times between the thrusting episodes.

Features indicating plate-margin tectonism, such as the presence of volcanics, acid intrusives, ophiolites and high pressure, low temperature metamorphics[14], are absent in central Australia; only retrograde metamorphism of the amphibolites and granulites of the basement occurred during the thrusting and folding. The Giles Complex, which contains the only ultramafics in central Australia, is made up of isolated intrusions[15]. The distribution of the various deformed zones and the widespread, relatively undeformed nature of the late Proterozoic and Palaeozoic platform sediments preclude any association of orogenesis with subduction, as does the continuity of contemporaneous structural features across major dislocations. The style of basement thrusting and gravity modelling[16], suggest that deformation was intracratonic and compressive. It was probably confined to the crust.

Palaeozoic deformation of the central Australian shield affected an area that was remote from the nearest continental margin. Lower Palaeozoic palaeomagnetic results from northern[17], central[18], and southern and western Australia[19] suggest that these regions have not experienced large lateral displacements with respect to one another since Cambrian time. Furthermore, the northern and central Australian results indicate that these regions have acted as a single unit at least since the late Proterozoic. The orogenic events should be interpreted in terms of a single central Australian craton that underwent meridional compression while participating in the drift of Gondwanaland[20]. The intermittent, north–south drift of Gondwanaland during the Palaeozoic is now well established[21,20]. We suggest that rapid, intermittent drift of the large Gondwanide plate had intraplate orogenic repercussions, which are manifested in the prominent east-trending basement and cover structures in central Australia. Ancient zones of weakness in the crust imparted a mechanical anisotropy which provided loci for later thrusting; these may have coincided with old east-trending mobile belts now represented by deformed granulite zones. Recurrent thickening and warping of the crust[13] produced the observed unconformities in the Proterozoic and Palaeozoic basins. When Australia drifted from Antarctica, it probably did so along one of the approximately east-trending ancient zones of weakness–perhaps an old mobile belt, as has been suggested for the rifting of South America from Africa[22].

There is clearly a need for a broader plate tectonic theory of orogenesis. Results from the Precambrian cratons of Africa and North America[23,24] are consistent with the concept of intraplate orogeny. It seems that, within the limits of palaeomagnetic resolution, little relative motion has occurred between cratons and the intervening mobile belts have been interpreted as manifestations of ensialic tectonic phenomena. Accordingly, Piper *et al.*[24] suggested that a 'supplement' to the plate theory of Precambrian orogenesis is required. Glikson and Lambert[25] invoked a rift valley (aulacogene) mechanism to explain the development of certain West Australian mobile belts. We have further extended the plate theory of orogenesis to provide a viable basis for understanding the Palaeozoic deformed zones of central Australia.

Finally, it has been shown[26,27] that continental plates, in particular those carrying North America and Australia, are in a state of compression under horizontal maximum principal stresses. Within such continents, earthquake shocks are generally caused by thrust faulting[27,28]. Without invoking a driving mechanism, it is reasonable to expect that large deviatoric stresses existed in Palaeozoic continents and thus accounted for the deformed zones of central Australia.

We thank Drs L. P. Black, B. J. J. Embleton, I. B. Lambert, and A. J. Stewart, and W. B. Dallwitz, R. D. Shaw, A. T. Wells for critically reading the manuscript.

Diamond growth by sulphide reduction of CO_2

MARX[1] proposed that natural diamonds were formed by a reduction of CO_2 and other theories have been proposed to explain their formation[2–6]. Carbon dioxide is a common constituent[7,8] and has been found as a gas in natural diamonds[9]. Marx proposed that pyrrhotite is active in the reduction process because it has been found as an inclusion in diamonds[10]. Furthermore, thermodynamic calculations showed such a reduction reaction to be energetically possible:

$$2FeS(solid)+CO_2(gas)=2FeO(solution)+S_2(gas)+C(diamond) \quad (1)$$

Diamond formation by this reaction probably would result in inclusions containing either free sulphur or sulphur compounds, or both. To test this theory experimentally, natural diamond was oxidised by pure oxygen at a high temperature. Any included sulphur would be converted to gaseous SO and SO_2 which could be detected by analysing the products with a research mass spectrometer. The instrument is about 10^5 times more sensitive than any other spectroscopic method[11] and lends itself well to a study of minute quantities of a gaseous substance.

The mass spectrometer used was a 15.25-cm radius 90° sector type magnetic scanning instrument. The instrument, calibration and experimental procedures have been described[12].

Diamond fragments (16 g) were used[9]. The diamond was placed in a quartz tube which was evacuated by an oil diffusion pump to 10^{-7} torr. An oxygen atmosphere of 1 torr was then admitted to the sample tube. The sample was heated to a temperature of 1,050° C and maintained at that temperature for 45 min. The sample container was then placed in a dry ice–acetone bath and noncondensed components were removed by evacuation. Condensable substances were retained in the container. The remaining sample was analysed at room temperature using mass spectromatic techniques. Each experiment was duplicated three times. The weight of diamonds oxidised in each experiment was about 5.3 g.

No evidence for SO and SO_2 in the oxidation products was found in any of the three samples. The 16 g of oxidised diamond fragments comprised several hundred individual diamond crystals, some with visible inclusions, from Africa, Brazil and Arkanas. The detection sensitivity for sulphur was approximately 1 part in 10^9 with respect to other oxidation products. Thus, there was no evidence for the presence of pyrrhotite. This suggests that the reduction of CO_2 by pyrrhotite is not responsible for the formation of all natural diamonds. These limited data do not, however, rule out the possibility of some diamond formation by the reduction of CO_2 by pyrrhotite.

BIOLOGICAL SCIENCES

E. coli lactose operon ribosome binding site

IN *Escherichia coli*, protein synthesis is initiated with formylmethionine, coded by the triplet AUG. As the first step in translation, ribosomes bind to the AUG initiator codon in the presence of initiation factors, charged fMet-tRNA and GTP. The sequence or structure of a messenger RNA molecule must signal that a particular AUG triplet is an initiation codon, and the cell's ribosomes must recognise this region as containing a signal for initiation of translation. In a reaction suitable for *in vitro* protein synthesis, except that it contains only one species of charged tRNA, fMet-tRNA, ribosomes bind to and protect initiation regions from nuclease digestion. The ribosomes bind at the AUG initiator codon and cannot proceed any further due to the lack of charged tRNA species other than fMet-tRNA. In the hope of determining the characteristics peculiar to an initiation region in a mRNA molecule, a number of ribosome binding sites have been sequenced[1–8].

I have previously reported the sequence of the first 63 bases of the lactose operon mRNA transcribed from the (CAP-independent) UV5 promoter mutant[9]. Figure 1 shows this sequence. The first AUG triplet occurs at positions 39–41, and the succeeding bases, read in triplets, code for the first seven amino acids of β-galactosidase[10]. This was highly suggestive that translation might initiate at position 39 of the UV5 *lac* message, and that ribosomes should bind to and protect the surrounding region of RNA from nuclease digestion.

To verify that the region around the AUG codon at position 39 is a ribosome binding site, I have isolated the portion of the UV5 *lac* mRNA which ribosomes protect from digestion by RNase A (which cuts after C and U) and RNase T_1 (which cuts after G). Table 1 lists the

Table 1 RNase T_1 oligonucleotides recovered after protection of a protein synthesis initiation complex from RNase A or T_1 digestion

Oligonucleotide	Molar yield after digestion with RNase A	RNase T_1
G(A)	2-3	2-3
AUAACAAUUUCACACAG(G)	1/4–1/2	1
AAACAG(C)	1	1
CUAUG(A)	1	1
ACCAUG(A)	1	1
AUUACG(G)	1	1
AUUCACUG(G)	1/4	1/3–1/2

RNA was synthesised *in vitro* from UV5 *lac* DNA fragment template as previously described[9]. Synthesis was for 13 min at 25° C. After phenol extraction and two ethanol precipitations to remove unincorporated triphosphates, the ^{32}P-labelled RNA was taken up in 20 μl of 0.5 mM EDTA and incubated at 37° C for 15 min. Initiation complexes were formed in a 40 μl reaction mix similar to that described by Steitz[1] containing: 0.1 M Tris, *p*H 7.4, 0.05 M NH_4Cl, 5 mM $MgOAc_2$, 0.2 mM GTP, 2.5 mM β-mercaptoethanol, 6.6 A_{260} units ribosomes, about 100 μg crude initiation factors, and 1.0 A_{260} unit mixed tRNA charged with ^{35}S-formylmethionine. Ribosomes and initiation factors were prepared from *E. coli* B/r as described by Anderson *et al.*[15], except that: the preparative buffer contained 1 mM dithiothreitol instead of 6 mM β-mercaptoethanol; ribosomes were made up to 0.05 M Tris, *p*H 7.4 before the 2 M NH_4Cl wash; and initiation factors were dialysed into preparative buffer containing 5% glycerol, and made up to approximately 10% glycerol before storage at −70° C in plastic tubes. *E. coli* K12 mixed stripped tRNA (General Biochemicals) was charged with ^{35}S-methionine and formylated. Charging was assayed by precipitation in cold and hot TCA. After 12 min incubation at 37° C the reaction was cooled to 25° C, 75 μg ml^{-1} RNase A or T_1 was added and incubation was continued at 25° C for 15 min. The reactions were layered on to linear 3.8 ml 5-20% sucrose gradients in the buffer described by Kondo *et al.*[16], except that the $MgOAc_2$ concentration was raised from 5 to 10 mM. After centrifugation for 1 h at 55 K in the IEC SB405 rotor, about 20 fractions were collected directly into 3.5 ml scintillation vial inserts and the peaks of radioactivity determined by Cherenkoff counts. Typically about 1–3% of the counts sedimented with the ribosomes after RNase digestion. These fractions were pooled, precipitated with 2.5 volumes ethanol and 1/10 volumes 20% NaAc at −20° C overnight, extracted with phenol, and precipitated with ethanol twice. The protected fragment was digested with RNase T_1 and fingerprinted by standard procedures described by Barrell *et al.*[17]. The data above are compiled from three separate experiments with A, C and U-labelled RNA.

oligonucleotides found in RNase T_1 fingerprints of this protected region. These oligonucleotides fit into the portion of the UV5 *lac* message surrounding the presumed initiator codon.

Table 2 compares the sequence of protected regions isolated after digestion with RNase A or RNase T_1. Ribosome protection does not preserve a unique sequence from nuclease attack: the size of the protected fragment depends on which nuclease accomplished the digestion, and on its concentration and activity. At the 3′ end of the *lac* ribosome binding site, the T_1 fragment AUUCACUG is sometimes protected and sometimes clipped during digestion with either RNase A or RNase T_1. At the 5′ end the long T_1 fragment, AUAACAAUUUCACACAG, is always protected from RNase T_1 digestion, so its 3′-terminal G must be well shielded in the protected region. RNase A usually cleaves within this fragment, so some C and U residues at its 5′ end must be exposed. It seems to have no preferred cleavage site in this region.

Sequences of nine other ribosome binding sites have been published[1–7], as well as that of an anomalous site on Qβ RNA which *B. stearothermophilus* ribosomes bind and protect[8]. A long stretch at the 5′ end of MS2 RNA has also been sequenced, and this includes a region which probably contains the MS2 A protein initiation site; its sequence is very similar to that of the initiation region for R17 A protein, although the initiation codon is GUG[11,12].

Common features of initiation or ribosome binding regions are an AUG initiator codon, the sequence AGGA, the sequence PuPuUUUPuPu (Pu stands for purine), and one or more nonsense codons near the initiation site. Table 3 lists the sequences of the 11 known initiation regions, drawn so that similar sequences can be easily compared. All the initiation regions (or presumed initiation regions) which have been sequenced, except that for the MS2 A protein, include an AUG initiator codon. The *lac* ribosome binding site shares the sequence AGGA (positions 28 to 31 of the mRNA) with seven other ribosome binding sites[1–4,8,11] and the *lac* site has the sequence AAUUUCA (positions 18 to 24) which, with C substituted for a purine, resembles the sequence PuPuUUUPuPu found in six other initiation regions[1,4–6,11]. All but the *lac* site have a nonsense codon (UAA, UGA or UAG) within 15 bases of the initiator AUG; in *lac* the nearest nonsense codon (UAA) is 22 bases away. In some regions a stable conformation can be drawn with the AUG protruding at the 'ear' of a loop of RNA, but no such stable secondary structure is apparent in that of the *lac* operon. Table 3 also shows the site which *B. stearothermophilus* ribosomes protect on Qβ RNA[8]. This site probably contains the sequence AGGA, but it shares no other features with known initiation sites.

Though all these regions have a certain resemblance to one another, none of these common features alone, not even the AUG initiator codon, is an absolute requirement for ribosome binding. There is a GUG codon in the initiator region of the MS2 A protein[12]. Reinitiations occur *in vivo* in mutants of the *lac i* gene (which codes for *lac* repressor) which carry early amber mutations. Three different mutant

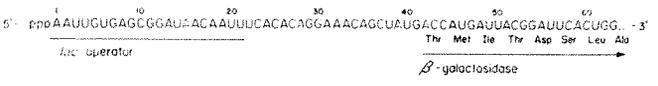

Fig. 1 The first 63 bases of the m RNA transcribed from the UV5 *lac* promoter[9]. The *lac* operator sequence is copied into bases 1 to 21. β-galactosidase initiates at the AUG codon at position 39, and the amino-terminal sequence of β-galactosidase[10] is matched to the triplets on the message which code for those amino acids.

Table 2 Ribosome binding region of the *lac* message

Maximum RNase T_1-protected fragment:
5′-AUAACAAUUUCACACAGGAAACAGCUAUGACCAUGAUUACGGAUUCACUG
Minimum RNase T_1-protected fragment:
5′-AUAACAAUUUCACACAGGAAACAGCUAUGACCAUGAUUACG
Minimum RNase A-protected fragment:
5′-AGGAAACAGCUAUGACCAUGAUUACGGAU

Oligonucleotides recovered from ribosome-protected fragments of the UV5 *lac* message were fitted into the sequence of the first 63 bases of this messenger (shown in Fig. 1). This table compares the minimum site protected by RNases A and T_1 with the maximum protected region. Gel electrophoresis of protected fragments cleaved by RNase T_1 reveals two main species. Sequence analysis of these species show that they differ by a single oligonucleotide, AUUCACUG, which is reflected in the low recovery of this oligonucleotide after protection and digestion with RNase T_1 (Table 1). But gel electrophoresis of fragments protected from RNase A digestion reveals a range of species between 30 and 40 bases long, and no preferred cutting sites are evident in fingerprints of protected RNA.

proteins all have fMet as their amino-terminal amino acid, but these restarts occur at amino acid residues which are normally translated as formylmethionine (AUG), valine (GUX) or leucine (CUX, UUA or UUG), so ribosomes seem to bind to codons which resemble the normal AUG initiation site, and then mistranslate[13,14]. Steitz has reported that *B. stearothermophilus* ribosomes bind *in vitro* to the RNA genome of the coliphage Qβ and protect a region

Table 3 Sequences of ribosome binding sites

Sequences of ribosome binding sites, from indicated sources, aligned with respect to their AUG or GUG initiator codons. Nonsense codons *UAA*, *UGA* and *UAG* are in italics. The popular sequence PuPuUUUPuPu is underlined, and AGGA is boxed. Parentheses and commas mark uncertainties in fragment order.

which has no initiator codon, although it probably does include the sequence AGGA[8].

The *lac* operon ribosome binding site is the first to be sequenced from an *E. coli* operon. It is pleasing to find a close resemblance between phage and host protein synthesis initiation regions. But while there are similarities of sequence between many of the known ribosome-binding sites, the resemblance among all these sites is too casual to allow any conclusions about how ribosomes recognise initiation regions.

I thank W. Gilbert, E. Lazarides and J. Steitz for advice. A Biophysics Training grant from the National Institute of General Medical Sciences suported the work; ^{35}S-methionine was a gift from D. Ratner.

Incorporation of exogenous DNA into mammalian chromosomes

MANY reports[1–4] have shown that exogenous DNA can be taken up and incorporated into the nuclei of cells in culture as well as *in vivo;* but no morphological evidence has been presented to suggest that such foreign DNA actually becomes associated with the chromosomes of inoculated cells. The Indian barking deer, *Muntiacus muntjak*, has the lowest number of chromosomes yet reported for mammals, ♀ = 6; ♂ = 7 (ref. 5). The combination of such a low chromosome number and the unique morphology of each pair of chromosomes in the diploid set make this animal particularly attractive for comparative cytogenetic studies. The C- and G-banding patterns[6–8] have also been established for this animal which allow even more detailed comparisons to be made than those based solely on gross chromosome morphology.

The purpose of this study was to determine if sequences of highly repetitive exogenous DNA could be incorporated into the muntjak chromosomes and demonstrated cytologically. Cells were inoculated with the synthetic polynucleotide poly (dA)·poly(dT) and then chromosome preparations were carried through the C-banding procedure which demonstrates repetitive DNA sequences[9]. The results suggest that, on the basis of new C bands, poly (dA) · poly (dT) can be incorporated into the muntjak genome (Table 1). The normal C-banding pattern is contrasted in Fig. 1 with a representative example of a cell showing extra C bands which presumably are due to new areas of highly repetitious DNA in the chromosome. Control cells (inoculation conditions 1 and 2) consistently showed a pattern of staining confined to the centromere regions of the autosomes, the centromere and neck of the X chromosome, and the entire Y chromosome. The new C bands were usually observed at the terminal portion of chromosome pair 1.

Seventy-two per cent of metaphases from cells inoculated with only Earle's balanced salt solution (EBSS) had the diploid set of chromosomes. The deviation from diploidy was due primarily to the loss of the small Y chromosome in many metaphases. This was also true for cells inoculated with DEAE · dextran poly(dA) · poly(dT), or the combination of the two. Extra C bands were observed only in the cells treated with poly (dA) · poly (dT) alone or in combination with DEAE · dextran and they occurred with approximately equal frequency in the two conditions.

a *b*

Fig. 1 C-banding patterns of *Muntiacus muntjak*. Cells were treated as described in Table 1. Chromosome spread (*a*) represents control cells inoculated with EBSS only (condition 1), and (*b*) was taken from cells inoculated with poly (dA) · poly (dT) (condition 3). Arrows point to extra C-bands as compared with controls.

Various studies[1,3,4] have shown that exogenous DNA is taken up by mammalian cells and becomes intranuclear to the extent of from 0.5 to 5% of the host cell DNA, but breakdown of the exogenous DNA followed by resynthesis in the nucleus would lead to an apparent nuclear incorporation of the foreign DNA. It has been estimated that the amount of donor DNA that actually becomes incorporated into the chromosomal material of the inoculated cells is less than 0.3% of the host cell DNA[3].

Our study avoids many of the inherent technical problems associated with previous biochemical and biophysical approaches to studying the incorporation of exogenous DNA into mammalian cells. Breakdown and reutilisation of the added poly (dA) · poly (dT) would not be expected to alter the C-banding pattern of the chromosomes, and only the portion of poly (dA) · poly (dT) that becomes associated with the chromosome would be detected by the C-banding technique. Since synthetic homoribopolynucleotides can be taken up by intact mammalian cells[11] without the addition of DEAE·dextran, it is not surprising that there was no difference in the frequency of extra C bands between cells treated with poly (dA) · poly (dT) alone or in combination with DEAE · dextran. The appearance of the extra C bands only at the terminal portion of the chromatids of specific chromosomes is of particular interest in that it suggests new DNA is added at specific sites and that certain chromosomes are more likely to be involved than others.

Table 1 Effect of synthetic DNA on chromosomes of *Muntiacus muntjak*

Inoculation	No. of cells examined	No. diploid (%)	No. with extra C bands (%)
1. EBSS	132	95(72)	0
2. DEAE·dextran	104	60(58)	0
3. poly(dA)·poly(dT)	263	162(62)	30(11·4)
4. DEAE·dextran+ +poly(dA)·poly(dT)	190	150(79)	19(10·0)

Fibroblast cells of the male muntjak were grown in medium MAB 87/3 (ref. 10) with 5% foetal bovine serum screened for coliphages. Slide culture chambers (Bio-Tek) were inoculated with cells and allowed to incubate at 37° C for 2 d to reach log phase of growth and about 1/2 confluency. Inoculation conditions included: (1) EBSS only; (2) DEAE-dextran (DEAE·D) (Pharmacia) (100 μg ml^{-1}) in EBSS; (3) poly (dA) · poly (dT) (PL Biochemicals) (2 μg ml^{-1}) in EBSS; and (4) DEAE·D (100 μg ml^{-1}) and poly (dA) · poly (dT) (2 μg ml^{-1}) in EBSS. Each culture was incubated with one of the above solutions for 15 min at room temperature, then rinsed once with Tris-buffered saline, and fed with 2.5 ml of complete growth medium. After about 36 h at 37° C, colcemide was added to a final concentration of 0.025 μg ml^{-1} and cultures incubated an additional 16 h. Medium was then replaced by a hypotonic solution consisting of medium without serum:H_2O (1:2) for 20 min. Subsequent fixation was in acetic:methanol (1:3), and C-band staining was according to the procedure of Arrighi and Hsu[9]. C-band differentiation was enhanced by a rapid rinse in 50% methanol or a 5 min rinse in 10% methanol followed by a distilled H_2O rinse and air-drying. Metaphase spreads from each culture were then examined at 1,000× for exact count and C-banding patterns. The poly (dA) · poly (dT) used in these studies had a buoyant density of 1.644 in neutral CsCl, $S_{20,w} = 7.9$, and molecular weight = 5×10^5.

The observations reported here are consistent with the hypothesis that under certain conditions exogenous DNA can be taken up by cells and incorporated into the cell genome. An alternative explanation for the extra C bands is that poly (dA) · poly(dT) has indirectly induced the changes in banding patterns. Direct evidence for the incorporation of poly (dA) · poly (dT) into the chromosomes will require *in situ* hybridisation studies. If the new C bands prove to be of poly (dA) · poly (dT) origin and if they are heritable, it should be possible to use synthetic nucleic acids in gene therapy rather than viruses which carry unnecessary and often unwanted genetic information in addition to that which may be therapeutically useful.

R.M.P. was a post-doctoral fellow supported by a National Institutes of Health fellowship from the Public Health Service. Dr T. C. Hsu, University of Texas, gave us muntjak fibroblast cells.

Site of attachment of J chain to human immunoglobulin M

In spite of a remarkable similarity of the general polypeptide chain structure of immunoglobulins, their molecular weights vary from 150,000 to 950,000 because some occur in monomeric (IgG, IgD and IgE) and others in monomeric or polymeric forms (IgA and IgM) (ref. 1). The largest immunoglobulin, IgM, appears in a stellate configuration of five disulphide-linked subunits (IgM_5), each consisting of two pairs of covalently linked heavy (μ) and light (κ or λ) chains[2]. Recent evidence shows that polymeric immunoglobulins, whether composed of dimers, tetramers or pentamers, contain one molecule of an additional polypeptide, termed J chain[3-5]. Produced within the same cells as immunoglobulins, J chain becomes attached to polymeric IgM and IgA during the final stages of intracellular assembly[6-8]. Available results indicate that this polypeptide is essential for polymerisation of monomeric immunoglobulins[9,10], has a molecular weight of about 15,000 (refs 11–13), and is covalently attached by disulphide bonds to the Fc region of IgM (refs 14–16). Although the covalent structure of μ chain has been determined[17], the exact location of the disulphide bond(s) connecting J chain to μ chain has not been known. To investigate this question, we used available information concerning fragmentation of IgM and of μ and J chains by cleavage with cyanogen bromide (CNBr) (refs 17–20). Because

ECONOMIC ENTOMOLOGY IN THE TROPICS

K. P. LAMB

April 1974, viii+196pp., £4.00/$11.00
0.12.434650.2

This book systematically reviews the main insect pests of tropical crops and introduces the reader to the ecology of pest control, host resistance and insecticides and their application. While it is orientated towards the needs of developing countries in the humid tropics with special reference to the Oriental and tropical Australian regions, major pests of crops from other parts of the tropics are also considered as are some insects of medical and veterinary importance.

OPTICAL ASPECTS OF OCEANOGRAPHY

edited by N. G. JERLOV and E. STEEMANN NIELSEN

April 1974, xvi+494pp., £10.50/$29.50
0.12.384950.0

In this volume are collected 19 invited papers presented at the Symposium on Optical Aspects of Oceanography held in Copenhagen during June 1972. The purpose and the spirit of the meeting was to describe recent developments in ocean optics, laying emphasis on applications in physical oceanography and marine biology and providing a forum for workers in optical oceanography.

GERIATRIC MEDICINE

edited by W. FERGUSON ANDERSON and T. G. JUDGE

March 1974, x+328pp., £4.80/$12.50
0.12.057250.8

This book is based on papers presented at an International Conference on Recent Advances in Geriatric Medicine held in Glasgow in September 1972.
The carefully edited papers cover the five fields of geriatric medicine — teaching, research techniques, medicine of old age, nutrition and sociology. The resultant text represents a very up-to-date account of current thinking in geriatric medicine.

MICROWAVE SPECTROSCOPY OF FREE RADICALS

ALAN CARRINGTON FRS

April 1974, x+264pp., £4.80/$12.50
0.12.160750.X

Over the past decade much research has taken place on molecules in open shell electronic states, and, in his book, Professor Carrington draws together the threads of this diverse and sometimes difficult subject. One of his main aims is to show that although the experimental approaches differ considerably, the major problems being tackled are very similar. The principles of these many and varied experimental techniques are described—at a fairly elementary level and with a clarity which even undergraduates will appreciate—and the important aspects of the underlying theory are outlined, so that the work's basic approach is problem-orientated rather than method-orientated.

THE CELL IN MEDICAL SCIENCE
VOLUME 1

edited by FELIX BECK and JOHN B. LLOYD

July 1974, xiv+366pp., £7.80/$20.25
0.12.084201.7

The Cell in Medical Science is intended to provide the basis of a cell science course for students reading for Honours B.Sc. and similar degrees, who already have an elementary knowledge of the subject. They will be particularly useful to medical students specializing in cell biology during an elective period or during an intercalated year of study leading to an Honours degree. They are, however, equally suitable for advanced students in any of the biological sciences that carry a substantial cell biology component. Volume I deals with the generalized cell unit and chapters are devoted to its principal organelles.

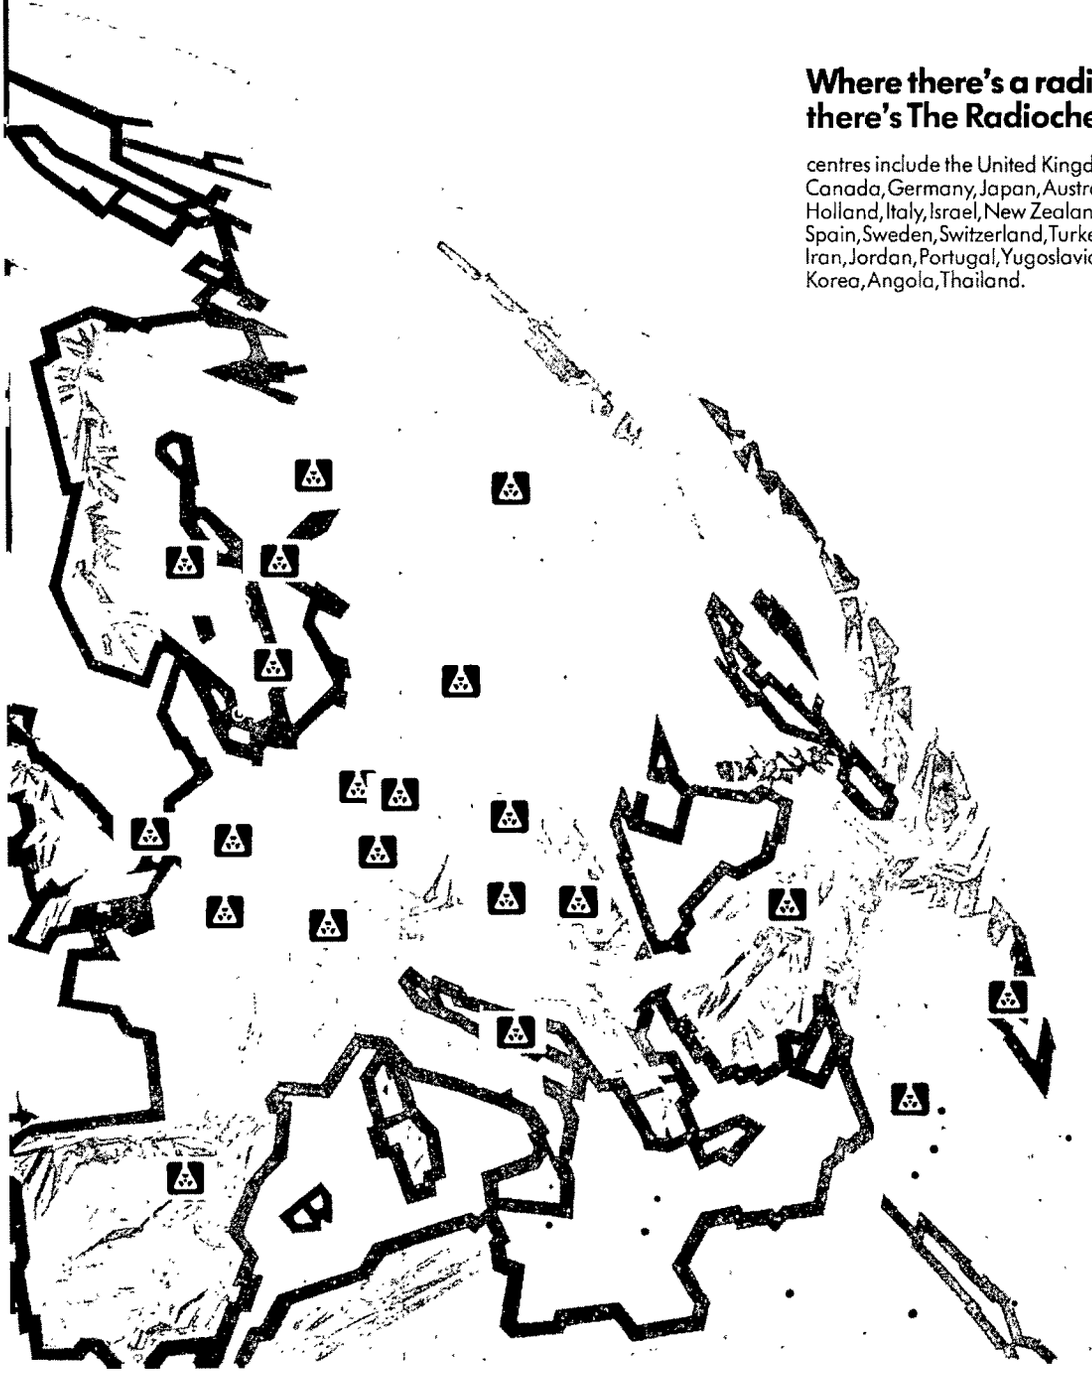
The Radia

chemical Centres

We concentrate on being a truly international operation; our two associate companies and 30 distributors form the largest and most widespread radiochemical network in the world. Both associates, and some of the regional agencies, carry their own stocks, and all are fully geared to provide first class delivery, servicing and on-the-spot technical advice.

Our technical customer liaison rests firmly in the hands of highly qualified scientists who are as familiar with the applications of our products as with their capabilities, and are as conversant with new research techniques as with established procedures.

Our customer service teams always provide prompt technical advice, and our most experienced scientists will often visit your laboratories to discuss particular problems in the use of radiochemicals.



Further information on our research radiochemicals service is available from your local distributor–please write to us for his name and address.

Plenum proudly announces the publication of a major work covering the etiology, biology, and therapy of the disease. This multi-volume treatise, guided by a highly-respected group of eminent scholars, offers specialists a reference sourcebook of unparalleled quality and breadth. It is destined to become the basic scientific guide for research workers in this critical field.

The first volumes on etiology are scheduled to be published this winter and subsequent volumes on the basic biology of the disease and the scientific basis of therapy will be published in the near future.

A **SPECIAL CHARTER SUBSCRIBER'S DISCOUNT** is available for this landmark work if a **Continuation Order** is placed now for all volumes in this treatise. **CHARTER SUBSCRIBERS** will receive a 15% discount off the list price of each volume in the treatise.

forthcoming

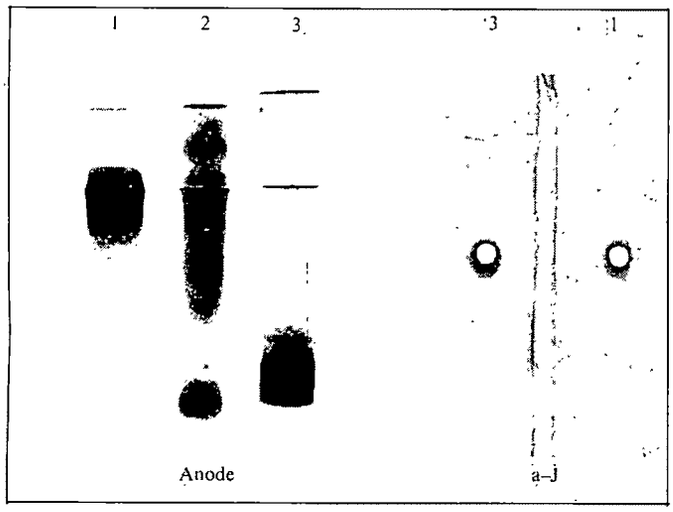

Fig. 1 Disc electrophoresis[22] and immunoelectrophoresis with an anti-J chain serum (a-J) (ref. 23) of CNBr cleaved IgM (1), fraction A Fig. 2 (2), and fraction A purified by DEAE-ion exchange chromatography[23] (3). Lyophilised IgM was dissolved in 70% formic acid at 2% protein concentration and cleaved with CNBr for 4 h at room temperature. The amount of CNBr was double that of the protein. After dilution with ten volumes of distilled water, the material was lyophilised.

this procedure leaves disulphide bridges intact we reasoned that the portion of μ chain(s) linked by these bridges to J chain would be obtainable as a CNBr fragment.

IgM isolated from serum of a patient with Waldenström's macroglobulinaemia[21] was cleaved with CNBr (ref. 20), and the products were examined by disc electrophoresis at *p*H 9.4 (ref. 22) and by immunoelectrophoresis with an antiserum to S-sulphonated J chain[23]. CNBr treatment released a fragment with the electrophoretic mobility and antigenic determinants of J chain (Fig. 1). Purification of this fragment was achieved by extracting CNBr-cleaved IgM with a 1% ammonium bicarbonate buffer brought to neutrality by bubbling with CO_2. Whereas most large fragments are insoluble in this buffer and are removable by centrifugation, fragments containing J chain are soluble and can be further purified by gel filtration through Sephadex G-200 (Fig. 2) and subsequent DEAE-ion exchange chromatography[23]. Disc electrophoresis at *p*H 9.4 and polyacrylamide electrophoresis in the presence of sodium dodecylsulphate[24] showed the purity of this fragment, which reacted with an anti-J chain serum but not with antisera to IgM, or κ and λ chains (Meloy Laboratories).

The molecular weight of a purified J chain-containing fragment was established by sedimentation equilibrium ultracentrifugation in 5 M guanidine-HCl[12]. The average molecular weight of three samples (A_{280nm} = 0.4–0.7) was 15,700 (range 15,400–15,900). Peptide maps and amino acid analyses[20] strongly resembled those of isolated J chain. This fragment, extensively reduced and alkylated, was applied on a column of Sephadex G-25, to separate individual components that were connected by disulphide bonds (Fig. 3). Resulting fractions were desalted, lyophilised, and their amino acids were analysed (Table 1). The first and largest fraction (B1) contained amino acids in proportions resembling those of J chain and its large N-terminal fragment[20]. The second fraction (B2) contained amino acids found in a fragment obtained by CNBr cleavage of isolated J chain[19,20]. The presence of a homoserine residue in B1 and its absence from B2 indicated that the former corresponded to the N-terminal and the latter to the C-terminal parts of J chain. The third fraction (B3) lacked homoserine, was eluted in the same position on Sephadex G-25 as the C-terminal octapeptide of α chain[20], and had an electrophoretic mobility and amino acid composition like that of the C-terminal octapeptide of μ chain[18,25]. These results indicate that the peptide in fraction B3 originated from the C-terminal end of the μ chain and that J and μ chains are connected by a disulphide bridge between the penultimate cysteine residue of μ chain and a cysteine residue in the J chain. The molecular weight of the J chain-containing fragment implies the presence of one, perhaps two, octapeptides.

Cysteine residues involved in inter-IgM_s disulphide bonds are located at position 414 from the N-terminal end of the μ chain[17,26,27]. Attachment of J chain to the penultimate cysteine residue (position 575) of only one or two C-terminal octapeptides indicates that J chain does not join individual IgM_s to form a pentameric molecule of IgM. If J chain, as well as previously described inter-IgM_s disulphide bridges, were to join five IgM_s to form a pentameric molecule, at least five of the ten C-terminal octapeptides would appear in association with J chain. In such a case a considerably increased molecular weight would be evident. Moreover, since at least two cysteine residues of J chain are involved in an intra-chain disulphide bridge[20], only four cysteine residues would be available to interact with IgM_s.

Of five known classes of human immunoglobulins, partial or complete amino acid sequences of the C-terminal parts of heavy chains have been determined for two monomeric immunoglobulins, IgG (ref. 28) and IgE (ref. 29), and for the two polymeric

Amino acid analyses were performed on a Beckman 120 C amino acid analyser modified for single column, high speed analyses. Samples were hydrolysed in constant boiling HCl at 108° C for 24 h. All values represent the average of two or more analyses.

* Compiled from previously reported values[4,13].

† Obtained by CNBr cleavage of isolated J chain; small fragment separated on Sephadex G-25 (ref. 20).

‡ Corrected for losses due to acid hydrolysis.

§ Determined as cysteic acid[35].

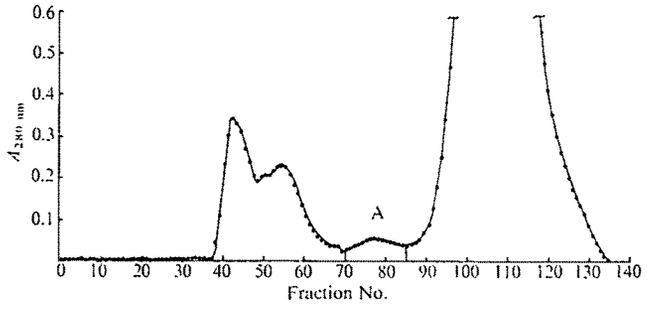

Fig. 2 Gel filtration of material obtained by extraction of CNBr-cleaved IgM with 1% ammonium bicarbonate solution saturated with CO_2 to neutrality. Extracted material was lyophilised, dissolved in 5 M guanidine-HCl, and applied on a column (2.6 × 100 cm) of Sephadex G-200 in 5 M guanidine-HCl. Material with electrophoretic mobility and antigenic determinants of J chain was present in fraction A (Fig. 1). Further purification was performed on DEAE Sephadex column[23].

immunoglobulins, IgM (ref. 17) and IgA (refs 30, 31). A comparison of the C-terminal portions of the heavy chains of these four classes revealed that α and μ chains extend beyond the C-terminal ends of the γ and ε chains by an additional 19 amino acids. The C-terminal octapeptides released by CNBr cleavage of μ and α chains are at the end of this extension[17,30,31]. In polymeric IgA, J chain is also disulphide-linked to the penultimate cysteine residue of the α chain[20,32]. The correspondence in sites of J chain attachment to μ and α chains and the pronounced homology of the two latter chains indicate that this region of both heavy chains is associated with the tendency of IgA and IgM molecules to polymerise.

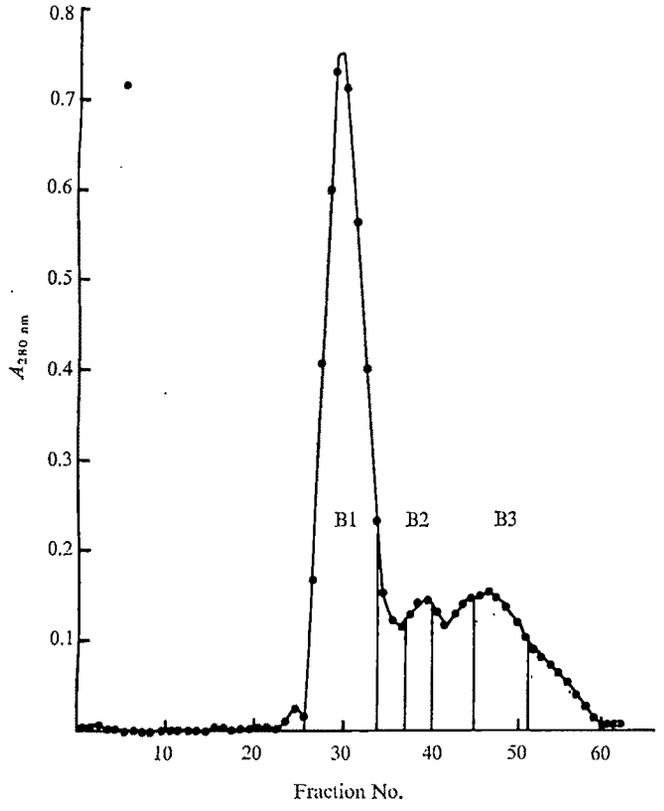

Fig. 3 Gel filtration of purified fraction A, reduced with 0.2 M 2-mercaptoethanol and alkylated with iodoacetamide[20]. A column (1.5 × 35 cm) of Sephadex G-25 fine was equilibrated in 5 M guanidine-HCl. Fraction B2 was further purified by rechromatography on the same column. Desalting was performed on a Sephadex G-10 column in 1% ammonium bicarbonate buffer.

Nevertheless, the mechanism of polymerisation remains speculative. A successive disulphide bond interchange reaction initiated by J chain has been suggested[5,13,33,34]. The incongruity between the necessity of J chain for polymerisation[9,10] and the variant positions of the cysteine residues involved in the inter-IgM$_s$ disulphide bonds (residue 414) and that of J chain attachment (residue 575) may be resolved by postulating a labile disulphide bond between these residues in a monomeric molecule as suggested for IgA (ref. 30). CNBr cleavage failed to release two disulphide-linked C-terminal octapeptides that were released only after subsequent disulphide bond cleavage. This finding led to the conclusion that, rather than being mutually connected by a disulphide bond, the penultimate cysteine residues of the two α chains of monomeric IgA apparently form an intra-α or inter-α chain disulphide bond with the cysteine residue located elsewhere on the α chain. Possibly the penultimate cysteine residues of intracellular monomeric IgM are a part of an analogous labile disulphide bond that, if cleaved in the presence of J chain, might initiate the release of -SH groups that particpate in inter-IgM$_s$ disulphide bonding. With the polymerisation completed, J chain remains attached to the penultimate cysteine.

Proportional increase of bursa-derived cells in chickens of the Obese strain

CHICKENS of the Obese strain (OS) spontaneously develop severe autoimmune thyroiditis during the first weeks of life, with clinical signs of hypothyroidism[1,2]. Serological tests reveal both circulating and bound thyroglobulin autoantibodies[3]. The lymphoid infiltration of the thyroid gland is characterised by a predominance of plasma cells and the formation of a large number of germinal centres[4]. In view of the histological and serological features, the spontaneous autoimmune thyroiditis of OS chickens can be considered as an appropriate animal model for human Hashimoto thyroiditis[2].

The major issue in research on autoimmune diseases is the question whether a primary autoantigenic stimulation (for example, by antigenically altered autologous material) of an essentially normal immune system leads to the development of disease, or if an abnormal immune system is incapable of maintaining the state of self tolerance. A combination of both mechanisms may also be involved in pathogenesis.

Investigations in the OS have provided data which support both a primary alteration of the thyroid glands before any signs of lymphoid infiltration do occur[5], and a disturbed function of the immune system as well[6,7]. With regard to the latter, it is noteworthy that the development of spontaneous autoimmune thyroiditis can be suppressed by neonatal or, even better, *in ovo* bursectomy[8], whereas neonatal thymectomy leads to an increase of frequency and severity[9] and also entails a significant augmentation of non-thyroid autoantibodies[6,7,9]. In contrast to experimentally induced autoimmune diseases, the spontaneous autoimmune thyroiditis is therefore considered to be 'B dependent'. From these and other studies[10], a new functional concept for the classification of autoimmune disease into B and T dependent extremes with intermediate forms has been proposed[11], and the diagnostic and therapeutic implications of this concept were discussed.

Table 1 Immunofluorescence tests on 10 NWL and 12 OS chickens at 19 d of embryonic life

Organ	Strain	% of lymphocytes reacting with: ABS	ATS	aIg
Bursa	OS	70	0	70
	NWL	71	0	57
Thymus	OS	2	92	0
	NWL	6	91	0
Spleen	OS	58	43	4
	NWL	29	64	1
Blood	OS	3	12	2
	NWL	ND	7	3

aIg, Anti-whole-chicken immunoglobulin antiserum raised in rabbits. Figures indicate mean % of cells reactive with respective antisera. The lymphoid cells of each organ were pooled from all OS or NWL chickens. ND, not done

Here we describe studies on the distribution of B and T cells in various lymphoid organs of OS chickens by means of immunofluorescence tests with specific turkey anti-chicken bursa cell (ABS) and anti-thymus cell (ATS) sera[12]. Antisera to chicken immunoglobulin have also been employed for the demonstration of immunoglobulin surface determinants as a further B-cell marker[13]. We thought that a postulated hyper-reactivity of the B-dependent portion of the immune system in the OS may be reflected in an altered distribution of B and T cells in the chickens' lymphoid tissues.

Table 2 Immunofluorescence tests on 5 NWL and 4 OS chickens 1.5 weeks after hatching

aIgM, Anti-chicken-IgM-serum raised in rabbits; aIgG, anti-chicken-IgG-serum raised in rabbits. Cell suspensions were not pooled. Figures indicate mean and s.d. ND, not done.

Lymphoid cells from the bursa of Fabricius, thymus and spleen were prepared by consecutively passing tissue fragments through 80 and 200 mesh screens and washing the cell suspensions in phosphate buffered saline (*p*H 7.2). Blood lymphocytes were obtained by sedimentation in polyvinylpyrrolidone (PVP) (refs 12, 13). The viability of the cells was always >90%. The reaction of cells with ABS or ATS was visualised in an immunofluorescent staining procedure on living cells[14]. The FITC-labelled antiserum to turkey immunoglobulin used in the indirect immunofluorescence tests was produced in our laboratories and characterised as described earlier[12]. Appropriate control experiments to exclude nonspecific staining were also carried out[12,13]. The conjugate was absorbed with chicken immunoglobulins. All readings were done on coded slides and with epi-illumination on a Reichert Zetopan microscope equipped with a HBO-200 mercury vapour lamp and suitable exciter and barrier filters[12]. After the immunofluorescent staining procedure the cells were counterstained with Evans blue to facilitate counting. IgM and IgG determinants on the surface of lymphocytes were detected in an indirect immunofluorescent test using specific rabbit antisera prepared as described elsewhere (B.A. and G.W., unpublished).

Table 1 gives the results obtained with cell suspensions of 19-d-old embryos. At this age there is a greater percentage of B cells in the spleen of OS chickens than in the spleen of NWL controls. No such feature was found in the other lymphoid populations tested. Using an anti-whole-immunoglobulin serum, there seems to be an increase of cells with immunoglobulin surface determinants (ISD) in the OS chicken bursa as compared with NWL birds.

Table 2 summarises the data from chickens 1.5 weeks after hatching. At this age an increase of B cells is not only found in the spleen but also in the thymus of OS as compared to NWL birds. Analysis of the cell populations

Table 3 Immunofluorescence tests on three NWL and three OS chickens 4 weeks after hatching

See legend for Tables 1 and 2

with chain specific anti-immunoglobulin sera revealed a preponderance of IgM over IgG-carrying B cells in the spleen of OS chickens. The additive values obtained with anti-IgM and anti-IgG were in good agreement with the figures obtained by incubating the cells with ABS. Four weeks after hatching a similar pattern was obtained (Table 3), but now the ratio of IgM to IgG carrying cells was also higher in the bursa of the OS as compared to NWL controls.

Table 4 shows that in 9-week-old OS chickens the proportion of B cells is increased in spleen, thymus and blood, and that here again most of these cells bear IgM on their surface. From the data obtained with chain-specific anti-immunoglobulin sera it seems reasonable to assume that the increment in B cells in lymphoid organs of the OS chickens is made up of IgM–ISD carrying cells. As in the 4-week-old animals, this IgM shift is also reflected in the bursal cell population.

A crucial observation in these studies was the altered splenic proportion of B and T cells already in OS embryos, that is, well before any signs of thyroiditis can be found. Thus, this increase of B cells in OS birds as compared with NWL chickens seems to be independent of the thyroiditis-induced metabolic or endocrine status. The occurrence of nearly 30% of B cells in the thymus of 1.5-week-old OS birds again emphasises this point. In NWL chickens such high numbers of B-cells in the thymus are only rarely attained, and if they do occur at all in healthy, unimmunised birds, they are found much later in life[15].

It may be hypothesised that the abnormal invasion of the OS thymus by B cells may impair normal maturation and regulatory processes in it, or that some primary derangement of the thymus function is a prerequisite for such an abnormal immigration of B cells. The late appearance of an increase in B cells in OS chicken blood may be explained either by the fast migration of 'pathological' B cells from blood to the tissues and thus the maintenance of normal levels of B cells in the blood for a longer period until the capacity of the peripheral lymphoid tissues for B cells is saturated, or by a selective microenvironment specifically attracting B cells into the prospective lymphoid organs early in the animals development.

Table 4 Immunofluorescence tests of four NWL and four OS chickens at 9 weeks of age

Organ	Strain	% of lymphocytes reacting with: ABS	ATS	aIgM	aIgG

See legend for Tables 1 and 2

Attempts to delineate B and T cells in NZB mice, the other well established model of spontaneous autoimmune disease, gave ambiguous results[16,17]. An alteration of the proportion of T cells to B cells has only been observed very late in the animals life, after the onset of clinical symptoms of the disease.

Our results are the first step towards a diagnostic application of the concept of B and T dependent autoimmune diseases[10,11]. As stated above, this concept is only concerned with the effector cells, and, in the case of OS chickens, the postulated hyper-reactivity of the B cell system does not exclude the posssibility that the initial aetiological factor in this strain may be a deficient T-cell depressor compartment[2]. In addition, the present approach may not only provide information about diagnostic aspects of autoimmune disease but also entail the use of appropriate T or B-cell specific immunosuppressive procedures. In the case of the OS, this point has already been substantiated by suppressing the spontaneous autoimmune thyroiditis with anti-bursa cell[18] or anti-immunoglobulin sera (G.W., B.A. and W. Johnson, unpublished). That this concept may also be true for human autoimmune diseases was confirmed in recent studies by Chused *et al.*[19] who demonstrated a significant increase of B cells in Sjögrens syndrome.

Reversal of immunological tolerance by cyclophosphamide through inhibition of suppressor cell activity

IT has been shown in mice that specific immunological unresponsiveness to contact sensitisation with picryl chloride induced by pretreatment with picryl sulphonic acid is a positive phenomenon rather than an absence of specific immunocompetent cells[1]. In this system it was shown that transfer of lymph node cells from unresponsive to normal mice would limit the recipients' contact sensitivity response to picryl chloride and that these cells had characteristics suggesting that they were T as opposed to B cells[2]. We should like to report that a similar state of unresponsiveness to the dinitrophenyl group in guinea pigs can be broken by treatment with cyclophosphamide (CY) just before sensitisation and this is associated with the return of the ability of T cells to proliferate in the draining lymph node as part of the immune response.

The guinea pigs used were of the outbred white spotted Himalayan strain (400–450 g). Tolerance was induced by two intravenous injections of 500 mg kg^{-1} dinitrobenzene-

Table 1 Reversal of tolerance to dinitrophenyl hapten by cyclophosphamide

Experimental protocol		Mean skin reactivity				PCA titre*
	Time after sensitisation (d)	14	28	56	70	
1 SO_3–SO_3	DNFB (CFA)	0 (6)	0 (6)		0 (6)	0 (6)
2 SO_3–SO_3 CY (3 d)	DNFB (CFA)	1.25 (6)	1.0 (5)		1.0 (5)	1:22 (6)
3 SO_3–SO_3 CY (14 d)	DNFB (CFA)	0 (6)		0 (6)		1:7 (6)
4	DNFB (CFA)	1.9 (6)				1:30 (7)

6 SO_3–SO_3 CY (3 d)	DNCB (contact)	1.1 (5)	0.5 (5)		0.75 (4)	
7	DNCB (contact)	1.3 (8)				

* 21 d after sensitisation.

SO_3–SO_3 indicates $DNBSO_3$ given at intervals of 14 d. In experiments 1, 2, 5 and 6 sensitisation was with DNFB in CFA or contact with DNCB 14 d after the last dose of $DNBSO_3$. In experiments 2 and 6 sensitisation was preceded by CY, 3 d previously. In experiment 3 sensitisation was with DNFB in CFA 28 d after the last dose of $DNBSO_3$ and was preceded by CY, 14 d previously. The figures in parentheses refer to the number of animals in each experiment.

sulphonic acid sodium salt ($DNBSO_3$) with an interval of 14 d, the last dose being 14 or 28 d before an attempt at sensitisation with 500 μg of 2, 4-dinitrofluorobenzene (DNFB) in complete Freund's adjuvant (Difco) (CFA) or contact with 50% 2, 4-dinitrochlorobenzene (DNCB) in acetone on the ear. Sensitivity was tested by contact with 0.09, 0.05 and 0.03% DNCB in acetone on the flank. The intensity of skin reactions was assessed 24 h later as described previously[3]. Animals were injected intraperitoneally with 250 mg kg^{-1} CY either 3 or 14 d before sensitisation. Antidinitrophenyl antibodies were detected three weeks after sensitisation by passive cutaneous anaphylaxis[4]. Auricular lymph nodes draining the site of application of a sensitising dose of DNCB 4 d previously were examined for immunoblast (large pyroninophilic cell) proliferation in paracortical areas by counting the number of these cells in a microscopic field of diameter 450 μm. At least 10 lymph nodes were examined in each group.

Table 1 shows that CY given 3 d before sensitisation, 14 d after the last dose of $DNBSO_3$ effectively reverses the unresponsiveness of guinea pigs to DNFB or DNCB. Reversal of unresponsiveness was found both with contact sensitivity (a cell-mediated immune phenomenon) and in the production of humoral antibodies detectable by PCA. Reversal of unresponsiveness in contact sensitivity persisted beyond 70 d after immunisation and therefore was not a temporary phenomenon. But if sensitisation was not attempted until 14 d after CY, no reversal of tolerance could be detected in contact sensitisation although low titres of PCA antibody were produced. This would indicate that sensitisation had to be within a limited period after CY to be fully effective.

A comparison of the effect of these various measures on T-cell proliferation in the lymph node draining the site of sensitisation is shown in Table 2. It can be seen that the development of unresponsiveness by treatment with $DNBSO_3$ is associated with an eight-fold reduction in the number of immunoblasts seen 4 d after sensitisation with DNCB. Treatment of these DNCB unresponsive animals with CY 3 d before sensitisation was associated with a four-fold rise in the number of immunoblasts to the level found in control animals given CY 3 d before sensitisation. But if sensitisation was delayed to 14 d after CY, the level of immunoblasts in the draining node did not return to even half the level found in control animals sensitised 14 d after CY, which had not been previously made unresponsive with $DNBSO_3$. These findings seem to parallel the peripheral manifestations of the immune response. The return of ability of unresponsive animals to react is associated with a reversal of the depression of the ability of T cells to proliferate in the draining lymph nodes following sensitisation. The failure to show reversal of unresponsiveness if sensitisation is delayed 14 d after CY corresponds with an inability to obtain a level of immunoblast proliferation nearer to that found in control sensitised animals.

The increased proliferation of T cells in tolerant animals treated with CY just before sensitisation cannot be simply a rebound phenomenon, since in normally sensitised animals pretreatment with CY results in a significant decrease in immunoblasts in the draining node.

The preferential inhibition of suppressor cell activity by CY has been demonstrated previously in normal immune responses. These include contact sensitivity and the Jones–Mote type of delayed hypersensitivity in the guinea pig[5–7]. Cyclophosphamide seems to act on immunological mechanisms by depressing B lymphocytes in preference to T lymphocytes and is selectively cytotoxic to those cells which are short lived and have a more rapid rate of turnover in peripheral lymphoid tissues[8–10]. These changes have been demonstrated both histologically and by the use of techniques to detect the θ antigen on lymphocytes on the mouse as well as by labelling studies using ^{125}IUDR and ^{51}Cr. As it can be reversed by treatment with CY, specific immunological tolerance might be considered to be the result of active suppression of the ability of T cells to proliferate in lymphoid tissue. These observations also indicate that, in this model, active suppression of T-cell function is on the afferent rather than the efferent side of the immune arc. Moreover we have observed that tolerance to DNCB can be reversed in syngeneic animals by transfusion of cells from actively sensitised donors. This is a further indication that suppression does not occur on the efferent side of the arc[11]. The finding that CY reverses tolerance if animals are sensitised 3 d later effectively excludes the role of enhancing antibody or circulating immune complexes in this system, as antibody levels would not be significantly reduced such a short time after treatment.

It seems therefore that CY has a preferential action on clones of suppressor cells, releasing effector cells for proliferation in cell-mediated immunity and in antibody production. Our results also show that suppressor cells can regenerate within 2 weeks of CY treatment, so that sensitisation by DNFB at this time fails. In spite of previous observations that CY acts preferentially on B rather than

• Notation of experimental protocol is as in Table 1.

T cells, our present observations do not exclude a role for short lived rapidly proliferating suppressor T cells that might be affected by CY in the same way as B cells and differently from effector T cells. At present one cannot say whether in this system the suppressor cells belong to a T or a B cell population.

A similar reversal of homograft tolerance has been described following irradiation in mice[12]. But in this and other reports the effect can only be obtained in weak or already terminating states of tolerance[13].

In conclusion we suggest that CY can break immunological tolerance by inhibition of a population of suppressor cells that effectively prevent T-cell proliferation in the draining lymphoid tissue and thus prevent the release of specifically sensitised cells into the periphery. Whether these suppressor cells act by preventing antigenic recognition or by direct inhibition of the proliferative phase of the immune response has not as yet been determined.

Augmentation of lymphocyte reactivity in guinea pigs, mice, monkeys and humans sensitised to BCG, dinitrochlorobenzene or nitrogen mustard

NONSPECIFIC augmentation of tumour immunity has been achieved through the use of Bacillus Calmette-Guérin (BCG), *Corynebacterium parvum*, *Toxoplasma gondii*, *Besnoitia jellisoni* and other intracellular parasites[1-4]. Nonliving preparations, such as cell walls from BCG, also cause nonspecific augmentation of tumour immunity[5]. The mechanisms underlying these effects are not clear. It has been postulated that amplification of macrophage or reticuloendothelial function is responsible for the enhancement of tumour immunity by these agents. In the mouse, BCG causes a change in the rate of activation of macrophages, as well as a change in their lysosomal content and bacteriolytic power[6,7]. In the guinea pig, there is an initial granulomatous reaction at the BCG inoculation site, followed by a peripheral histocyte-mediated destruction of tumour cells[8]. We have now examined the effect of intradermal BCG on the 'specific' and 'nonspecific' responsiveness of circulating lymphocytes. We also investigated the ability of two chemical agents to produce similar or additive effects.

Strain 2 guinea pigs were inoculated intradermally with either BCG or dinitrochlorobenzene (DNCB), or nitrogen mustard, or all three of these agents. Each agent produced a local delayed hypersensitivity reaction. BCG was given as an 0.1 ml inoculation of *Mycobacterium bovis* vaccine (Research Foundation, Chicago, Illinois). DNCB was given as an 0.1 ml intradermal inoculation containing 2,000 μg dissolved in acetone. Nitrogen mustard was administered as an 0.1 ml intradermal inoculation of 100 μg of Mustargen (Merck, Sharpe and Dohme) in physiological saline. Animals that received all three agents received three separate intradermal inoculations.

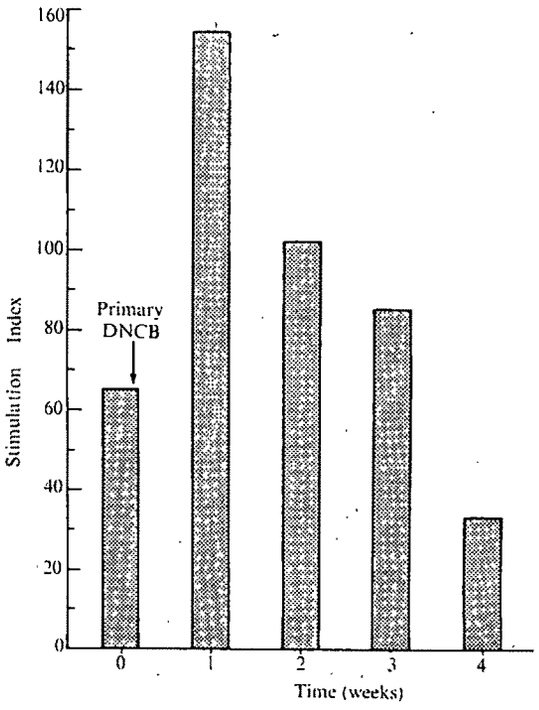

Fig. 1 Effect of primary DNCB exposure on lymphocyte responsiveness to PHA in 13 patients

Six weeks later, blood was drawn by cardiac puncture and lymphocytes were separated on Ficoll-Hypaque gradients and tested for reactivity against phytohaemagglutinin (PHA) and tuberculin purified protein derivative (PPD) using a microtechnique[9]. Two hundred thousand lymphocytes per well were incubated in a Falcon Microtest plate for 48 h with 10 μg of PHA or PPD, followed by a 24 h incubation with 2 μCi of ^{3}H-thymidine, and then liquid scintillation counting of the d.p.m. of the ^{3}H-thymidine taken up by cellular DNA. The same assay was used to test guinea pig, monkey and human circulating lymphocytes. Slightly different conditions were used to test mice, since lymphocytes were of splenic origin, and were incubated with PHA for shorter periods[10].

Table 1 shows a typical experiment in which guinea pigs treated with BCG had a higher responsiveness to PHA than did guinea pigs not treated with BCG. The same is true for reactivity against PPD. Pigs treated with a combination of BCG, DNCB and nitrogen mustard had the highest reactivities to PHA and PPD. Other studies showed that intradermal DNCB or nitrogen mustard alone also increased PHA responsiveness. Similarly, in mice, increased PHA reactivity of lymphocytes was observed in animals inoculated subcutaneously 10 d previously with 1,000–2,000 μg of DNCB.

Table 1 Effect of intradermal BCG, DNCB and nitrogen mustard on guinea pig lymphocyte stimulation by PHA and PPD

Sensitisation	^{3}H-Thymidine (d.p.m.) Media	PHA	PPD	Stimulation index of circulating lymphocytes PHA	PPD
Nothing	3,478 ± 428	4,869 ± 308	2,670 ± 74	1.4	0.8
BCG	3,769 ± 726	11,852 ± 1,845	6,834 ± 1,300	3.1	1.8
BCG, DNCB and nitrogen mustard	4,774 ± 1,282	17,023 ± 832	11,385 ± 3,797	3.6	2.4

The possibility of enhancement by DNCB and nitrogen mustard of BCG induced-lymphocyte responsiveness was then examined in seven rhesus monkeys. Two monkeys had received no previous BCG and were PPD negative. Five monkeys had been inoculated intradermally with 10^7 viable BCG organisms every 2 to 3 weeks for 4 months. On repeated skin testing with second strength PPD, two of the latter five had developed a positive PPD reaction, and two were negative to intradermal PPD in spite of repeated BCG administration. Blood lymphocytes from all these animals were tested for PHA and PPD reactivity (Table 2).

Table 2 Effect of BCG treatment on monkey lymphocyte stimulation by PHA and PPD

Monkey no.	BCG treatment every 2-3 weeks × 4 months	Skin reactivity to PPD	Stimulation index of circulating lymphocytes PHA	PPD
50	No	Neg.	6.0	0.86
605	No	Neg.	8.2	1.6
248	Yes	Neg.	21.3	6.0
922	Yes	Neg.	33.0	4.0
676	Yes	±	18.0	7.3
730	Yes	Pos.	8.5	4.3
708	Yes	Pos.	14.1	19.0

As expected, the PPD stimulation index was lowest in monkeys receiving no BCG (0.86–1.6), and considerably higher in treated monkeys (4.0–19.0). As was true in other species, the PHA reactivity was also enhanced by BCG, varying from 8.5 to 33.0, compared with 6.0 and 8.2 in the two control monkeys.

Four of the monkeys were then randomly chosen for intradermal inoculation with 0.2 ml of DNCB and 0.2 ml of nitrogen mustard. The preparations were the same as described above for the guinea pigs. When blood lymphocytes were tested 1 week later, there was an average increase of 106% in the PHA stimulation index and 221% in the PPD stimulation index. In two animals not treated with DNCB and nitrogen mustard, the average PHA and PPD stimulation indices fell 11% and 24% respectively. These data are summarised in Table 3.

Table 3 Effect of DNCB and nitrogen mustard on BCG-induced enhancement of lymphocyte responsiveness

Monkey no.	DNCB and nitrogen mustard	Stimulation index PHA	PPD	% Change in stimulation index PHA	PPD
730	No	3.4	2.5	− 60%	− 42%
605	No	11.4	1.5	+ 39%	− 6%
248	Yes	84.0	41.3	+ 300%	+ 583%
708	Yes	27.3	10.0	+ 93%	− 47%
922	Yes	26.7	9.8	− 19%	+ 145%
676	Yes	27.1	22.1	+ 51%	+ 203%

In the final monkey experiment, three monkeys (Nos 708, 922 and 676) which had previously received BCG, DNCB and nitrogen mustard were given all three agents again. Their average PHA stimulation index 1 week later was 63, representing average increases of 133% over the immediately previous values and 190% over the initial values. The largest increase of the three was in monkey 708, which was the only PPD positive animal in that subgroup.

In patients with or without previous BCG treatment, we have observed that topical application of 2,000 μg of DNCB increases PHA reactivity of circulating lymphocytes. The data from 13 patients with melanoma, sarcoma and adenocarcinoma are presented in Fig. 1. Although no patient was tested at every point, the composite of all the values shows a doubling of PHA responsiveness after the first exposure to DNCB. The average stimulation index 4 weeks after primary sensitisation was less than the average value before sensitisation. This may be due to an undershoot following the peak stimulation, or may reflect a lack of stability in this population of cancer patients, several of whom underwent surgery, radioisotopic scans or other diagnostic procedures during the interval of study. These factors are being evaluated. Patients exposed a second time to DNCB also showed enhancement of PHA responsiveness.

Our studies support the conclusion that agents that produce a delayed hypersensitivity reaction increase PHA responsiveness of the host's circulating lymphocytes. This enhancement of peripheral lymphocyte reactivity may be a primary pathway by which BCG is effective in tumour immunotherapy. As in some forms of chemotherapy, the combination of agents seems more effective than either agent alone. The application of this observation to immunotherapy and tumour-specific immunity is being examined.

During immunological monitoring the effect of one test on the results of another should be considered, as well as the effect of the test on the patient's immune status. Reactivity to DNCB has been found to be a favourable prognostic sign in patients undergoing surgery for malignancy[11]. It is also conceivable that the nonspecific stimulation of circulating lymphocytes produced by DNCB sensitisation has some adjunctive therapeutic value

Transplantation of allogeneic lymphoid cells specifically depleted of graft *versus* host reactive cells

GRAFT *versus* host (GvH) disease has been a major problem in the transplantation of allogeneic haematopoietic or immunocompetent lymphoid cells. In man, attempts to reduce the GvH effect of transplanted allogeneic cells, including HL-A matching[1,2], cell separation techniques[3], anti-lymphocyte globulin[4], and injection of small doses of bone marrow cells[5], have aided successful bone marrow transplantation. Various techniques have been used in animal systems[6-14] to reduce the GvH reaction by removing reactive cells from populations of lymphoid cells. So far, however, there has been no attempt to assess the potential value of such specifically depleted cells in transplantation.

Recently we have shown that one of these techniques, adsorption of immune cytotoxic thymus-derived (T) cells onto monolayers of target cells bearing the sensitising antigens, is greatly improved by centrifugation[15], thus giving 70–90% depletion of cytotoxic cells. These results encouraged us to apply this fractionation technique to deplete nonimmune lymphoid precursor cells carrying surface receptors for mouse alloantigens. We have now found that normal BALB/c ($H\text{-}2^d$) spleen cells can be depleted specifically of GvH reactive cells (against histoincompatible C57BL/6 ($H\text{-}2^b$) alloantigens), and that lethally irradiated C57BL/6 mice transplanted with the fractionated BALB/c allogeneic cells survive with no apparent signs of GvH disease.

Fractionation of normal BALB/c spleen cells on C57BL/6 spleen cell monolayers abolished their capacity to become sensitised *in vivo* against C57BL/6 alloantigens as measured *in vitro* by the ^{51}Cr release assay using EL-4 ($H\text{-}2^b$) labelled target cells (Table 1). The specificity of the adsorption was investigated using monolayers prepared with antigenically unrelated cells. BALB/c spleen cells which had been adsorbed on either BALB/c or SJL/J ($H\text{-}2^s$) monolayers or on empty dishes (not shown) retain the ability to become sensitised against C57BL/6 and elicit cell-mediated cytotoxicity (CMC) *in vitro* (Table 1, experiment 2). These results are consistent with the concept that precursor cells for CMC, known to be T cells[15,17,18], possess receptors on their surface which can recognise and bind specifically to the corresponding cell surface antigens.

We next investigated whether the fractionated spleen cells can reconstitute lethally irradiated allogeneic recipients in the absence of developing fatal GvH disease. C57BL/6 mice injected with: (1) unfractionated BALB/c spleen cells; (2) BALB/c spleen cells adsorbed either on BALB/c or on SJL/J spleen cell BALB/c monolayers, and (3) spleen cells adsorbed on empty plastic dishes, all developed GvH disease characterised by runting, and died within 2–4 weeks of inoculation. On the other hand, about 70% of the C57BL/6 mice that received 4–6 $\times$ 10^7 BALB/c spleen cells adsorbed on C57BL/6 monolayers survived more than 6 months with no signs of disease (Table 2). Control lethally irradiated SJL/J mice injected with 4 $\times$ 10^7 BALB/c splenocytes either unfractionated or depleted on C57BL/6 monolayer all died within 3 weeks (not shown).

Table 1 Failure of *in vivo* sensitisation of BALB/c spleen cells adsorbed onto C57BL/6 spleen cell monolayer

Experiment	No. of BALB/c donor cells	Spleen cell monolayer used for adsorption	Cell-mediated cytotoxicity at effector target ratio of 100:1	25:1
1	6×10^7	None	45.8 ± 0.9	39.5 ± 1.6
		C57BL/6	−0.2 ± 0.4	−0.06 ± 0.01
2	5×10^7	None	30.0 ± 0.04	23.2 ± 1.8
		C57BL/6 ($H\text{-}2^b$)	1.4 ± 0.04	0.02 ± 0.6
		BALB/c ($H\text{-}2^d$)	29.2 ± 0.8	15.2 ± 1.4
		SJL/J ($H\text{-}2^s$)	25.2 ± 0.4	21.9 ± 2.4
	None	——	−0.8 ± 0.27	−1.63 ± 0.4

Donor cells from 10–12-week-old male BALB/c mice were teased and a cell suspension was prepared in Eagle's minimal essential medium (MEM). Various numbers of fractionated or unfractionated lymphoid cells were injected intravenously into lethally irradiated (750–800 r., using a ^{60}Co source, 35 r. min^{-1}) male C57BL/6 mice of the same age. The mice were irradiated 2 h before inoculation and injected intraperitoneally with heparin (50 U) 15 min before cell administration. Antibiotics were included in the drinking water for the first 3 weeks after inoculation. Six (experiment 1) or 7 d (experiment 2) after inoculation mice were killed and their spleens were tested *in vitro* for cell-mediated cytotoxicity against ^{51}Cr-labelled EL-4 ($H\text{-}2^b$) target cells as described before[18]. Spleen cell monolayers used for adsorption were prepared by the technique described by Stulting and Berke[16], using poly-L-lysine (Sigma)-coated polystyrene Petri dishes (60 $\times$ 15 mm, Falcon No. 3002). Briefly, 8 $\times$ 10^7 to 10 $\times$ 10^7 (2 ml) spleen cell leukocytes suspended either in Dulbecco's phosphate-buffered saline (PBS) or in RPMI 1640 medium were added to each plate. The plates were incubated at room temperature for 45 min and then washed thoroughly with PBS. Adsorption was performed as described before[17]. 2 $\times$ 10^7 (2 ml) BALB/c spleen cells were added to each monolayer and incubated at 37° C for 45 min in a humidified atmosphere of 5% CO_2 and 95% air. The plates were then centrifuged at 80*g* for 5 min at 24° C in a PR-J (IEC) centrifuge using rotor No. 259 (IEC) and cups No. 384 (IEC). The nonadherent cells were collected after a brief agitation, washed once in MEM, counted, and used for inoculation. Cell-mediated cytotoxicity was measured essentially as described before[18]: 0.1 ml containing 2.5 $\times$ 10^4 ^{51}Cr-EL-4 cells in MEM + 10% foetal calf serum was mixed with 0.2 ml containing the appropriate number of spleen lymphocytes to yield the desired effector to target cell ratio. The cell mixtures were incubated at 37° C in a humidified atmosphere of 5% CO_2 and 95% air for 3 h on a rocking platform. After incubation, 1 ml of medium was added, the cells were centrifuged at 400*g* for 10 min, and the supernatant was counted for radioactivity. The results are expressed in specific percentage lysis ± s.e. and represent the mean of tests run in triplicate. The percentage specific lysis was calculated as follows:

$$\frac{\text{Test counts—background counts}}{\text{Total releasable counts—background counts}} \times 100$$

where background counts were released in the presence of normal spleen and total releasable counts represent approximately 80% of total counts.

At first, we thought that the fractionated BALB/c spleen cells used to inoculate the irradiated C57BL/6 mice could have been contaminated with C57BL/6 cells eluted off the monolayers during the adsorption procedure, so that the syngeneic C57BL/6 cells were actually responsible for protection and survival of the irradiated mice. This was ruled out as follows. Elution of C57BL/6 cells from the monolayers was estimated not to exceed 1.5 $\times$ 10^6 cells, or roughly 10% of the BALB/c spleen cells recovered from each monolayer. Mice inoculated with a mixture of 5 $\times$ 10^7 unadsorbed BALB/c cells and 5 $\times$ 10^6 C57BL/6 spleen cells (Table 2, experiment 2) all died, as did control mice inoculated with 5 $\times$ 10^7 unadsorbed BALB/c spleen cells. Moreover, BALB/c spleen cells fractionated on mitomycin C-treated (40 μg ml^{-1} containing 5 $\times$ 10^7 lymphocytes for 30 min at 37°C) C57BL/6 spleen cell monolayers could also reconstitute irradiated C57BL/6 mice.

The mice that survived the allogeneic transplant of fractionated cells were examined 30 d later for lymphoid cell chimaerism by complement-dependent cytotoxic assays using specific allogeneic antisera. The spleens were composed predomi-

Table 2 Survival of lethally irradiated C57BL/6 mice inoculated with fractionated allogeneic BALB/c spleen cells

* These results were derived 120 d after inoculation. A few animals died 1–5 d after inoculation and were omitted from the group.

nantly of host lymphoid cells (Table 3). These results, however, were not unexpected, for spleen cells have been considered to be a poor source of stem cells. The exact mechanism by which the animals remain alive is not known. Donor allogeneic spleen cells, incapable of triggering a GvH reaction, may serve as transient cells and help the host to recover from the immediate effects of irradiation.

These experiments show that: first, fractionated allogeneic spleen cells inoculated into lethally irradiated recipients permit the host to recover from the combined fatal effects of irradiation and GvH disease; and second, a specific compartment of immunocompetent GvH reactive cells can be depleted from a normal spleen lymphoid cell preparation by adsorption on allogeneic cell monolayers. Previous failures to demonstrate

Table 3 Origin of spleen lymphoid cells obtained from irradiated C57BL/6 mice that survived allogeneic spleen cell transplants*

Treatment	% Dead cells† Normal C57BL/6 spleen	Normal BALB/c spleen	Reconstituted spleen
Complement alone	15	15	15
Anti-BALB/c serum (1:10)	15	15	15
Anti-BALB/c serum (1:10) + complement (1:5)	15	85	20
Anti-C57BL/6 serum (1:10)	15	15	15
Anti-C57BL/6 serum (1:10) + complement (1:5)	70	15	65

* This group of mice was killed 30 d after inoculation of BALB/c spleen cells fractionated on C57BL/6 spleen cell monolayers.

† The values represent the percentage of lymphoid cells killed in a complement-mediated cytotoxic assay as determined by the trypan blue (0.2%) dye exclusion technique. Fresh rabbit serum was the source of complement after being absorbed with normal BALB/c and C57BL/6 spleen cells (2 volumes of serum + 1 volume of cells at 4° C for 1 h). Anti-BALB/c and anti-C57BL/6 sera were prepared in C57BL/6 and BALB/c mice, respectively, by three biweekly injections of 2×10^7 spleen cells. The spleen cells used in the cytotoxic assays were treated first with ammonium chloride (0.14 M) in Tris buffer to remove red blood cells. Spleen cells (3×10^5, 0.1 ml) were incubated with 0.1 ml of antiserum for 30 min at 24° C, then 0.1 ml complement was added and the mixture was incubated for a further 30 min at 37° C.

depletion of T helper cell[19] or of GvH reactive cells from sensitised[20] or nonsensitised[21] cells may have been due to technical problems and not to the absence of antigen-binding receptors on the precursor cells. It seems likely that the centrifugation step used by us in the adsorption process allows firm binding of the receptor-bearing cells to the membrane antigens. Our results indicate that unsensitised precursor cells carry antigen-binding receptors on their surface, and agree with the findings of Lonai *et al.*[13] and Altman *et al.*[14]. We believe that the techniques used in our study could be applied in bone marrow transplantation, immunodeficiency diseases, and the immunotherapy of cancer.

Subunit complex III-IV as the nucleotide binding site of Q_β replicase

OF the four subunits of Q_β replicase, I, III and IV are bacterial proteins and II is coded for by the phage genome[1,2]. Among host-derived subunits, I is identified as factor i, a protein which controls cistron-specific translation in *Escherichia coli*[3,4], and III and IV are identified as protein synthesis elongation factors, EFTu and EFTs (ref. 5), respectively.

Several lines of evidence indicate that EFTu and EFTu–EFTs interact with GDP or GTP (refs 5–8) and that EFTs stimulates the exchange of GDP bound to EFTu with unbound GTP (refs 9–12), but does not interact with these nucleotides. It has not been known whether EFTu and EFTs in the Q_β replicase perform functions analogous to those in protein synthesis.

Recent work in our laboratories (ref. 13 and unpublished results) has shown that GTP binding to EFTu–EFTs from *E. coli* HAK 88, a mutant with altered EFTs (ref. 14), is thermolabile and that this is also the case for Q_β replicase formed in infected cells. These results support the suggestion that subunit complex III–IV is concerned with nucleotide binding, or at least GTP binding.

I report here results concerning the nucleotide-binding site of Q_β replicase, which indicate that subunit complex III–IV can account for the ability of the enzyme to bind all four nucleotides, whereas I–II cannot, and that there are two distinct nucleotide-binding sites on the enzyme and its subunit

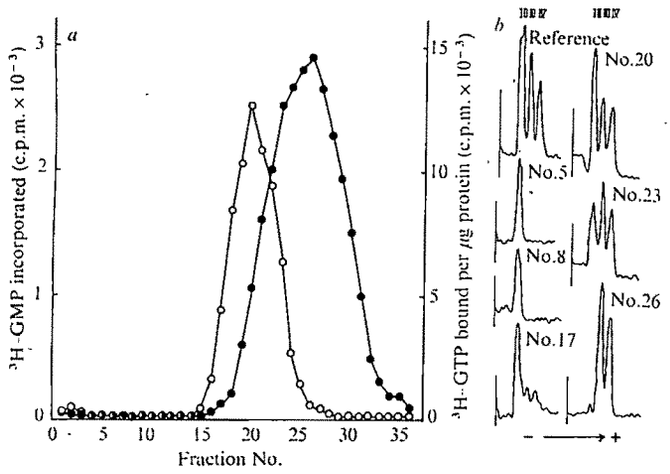

Fig. 1 Sedimentation pattern of Q_β replicase subunits carrying enzyme activity and GTP binding ability. Q_β replicase was purified as described previously[16]. The glycerol density gradient fraction with a specific activity of 5,500 U mg^{-1} protein was used and revealed only four bands corresponding to the enzyme subunits I, II, III and IV[1,2] using sodium dodecyl sulphate (SDS)-polyacrylamide gel electrophoresis[17]. Q_β replicase (200 U) was dissociated into its subunit complexes I-II and III-IV by dialysis for 4 h at 0° C against a buffer containing 0.01M Tris HCl (*p*H 7.6), 1 mM Mg acetate, 2×10^{-4} M EDTA, 1×10^{-4}M dithiothreitol and 5% glycerol. The dialysate was centrifuged on 5 ml of 10–30% glycerol density gradient made up in the same buffer for 17 h at 37,000 r.p.m. at 6° C in the RPS-40 rotor of Hitachi ultracentrifuge 55P-2. A fraction (0.15 ml) was collected from the bottom of the tube and aliquots were used for analysis of enzyme components by SDS-polyacrylamide gel electrophoresis[17], determination of protein concentration[18], Q_β replicase assay (○) with poly(C) as template[16] and ^{3}H–GTP-binding (●). The reaction mixtures for the GTP-binding assay contained in 0.25 ml: 25 μmol Tris HCl (*p*H 7.6), 2.5 μmol $MgCl_2$, 1 μmol 2-mercaptoethanol, 0.22 μCi ^{3}H–GTP (12 Ci mmol^{-1}) and enzyme components from the gradient. After incubation for 20 min at 30° C, the reaction mixture was passed with gentle suction through a nitrocellulose membrane filter (Sartorius MF 50, 0.45 μm, 12 mm) presoaked in a buffer containing 0.1M Tris HCl (*p*H 7.6), 0.01M $MgCl_2$, 0.025M NaCl and 4×10^{-4} M 2-mercaptoethanol and washed with 0.25 ml of the same buffer. The SDS-polyacrylamide gels (acrylamide 7.5% *bis*-acrylamide 0.2%, SDS 0.1%, sodium phosphate 0.1M, *p*H 7.5) were run for 3 h at 7.5 mA per gel, stained with Coomassie brilliant blue and destained[17]. The gels were scanned at 600 nm in a Toyo DMU-2 scanner. *a*, Q_β replicase and GTP-binding activities of fractions from the gradient; *b*, SDS-polyacrylamide gels of fractions from the gradient and the purified Q_β replicase as reference.

complex III–IV, one of which is GTP-specific and the other is probably common to nucleotides other than GTP or to all four.

To examine the binding of nucleotides to Q_β replicase and its subunit complexes I–II and III–IV, ^{3}H-nucleotide was incubated with protein, filtered through a nitrocellulose membrane filter and washed with a buffer as described in the legend to Fig. 1. ^{3}H-radioactivity bound to the membrane filter was then measured as described previously[15]. Q_β replicase was dissociated into subunit complexes I–II and III–IV as described by Kamen[2]. The two complexes were separated by centrifugation on a glycerol density gradient (Fig. 1). Subunit complex I–II sedimented in fractions 4 to 14 and subunit complex III–IV in fractions 25 and 26 of the gradient; replicase activity, assayed with poly(C) as template, appeared in fractions 17 to 24 with a main peak in fraction 20.

^{3}H-GTP binding was also determined in an aliquot of each fraction of the gradient. Essentially no ^{3}H binding was observed with fractions 2 to 14. Binding, which was first seen in fraction 16, reached a maximum in fraction 26 and declined in subsequent fractions. Fraction 26 contained the largest quantity of the III–IV complex. The amount of ^{3}H-GTP bound per μg of protein in fraction 20 was about 40% of that in fraction 26. The molecular weight of Q_β replicase and its subunit complex III–IV has been assumed to be 210,000 and 80,000 (refs 1, 2), respectively, and I found that the amount of ^{3}H-GTP bound per molecule of protein was about the same for these two components.

Binding of ^{3}H-GTP to Q_β replicase and its subunit complexes I–II and III–IV was also compared using various concentrations of protein and constant GTP (Fig. 2). The amount of ^{3}H-GTP bound increased linearly with increasing quantities of protein when the replicase or its subunit complex III–IV was used. The amount of ^{3}H-GTP bound per mole of subunit compex III–IV was about 85% of the amount bound per mole of enzyme. On the contrary, there was no detectable binding of ^{3}H-GTP when up to 5 pmol of subunit complex I–II was added.

Since no detectable protein, including replicase and its subunit complexes I–II and III–IV, pass through a membrane filter even in the presence of nucleoside triphosphates, it seems unlikely that they form a nucleotide-protein complex which could pass through the membrane. Further, since Q_β replicase activity was reconstituted from subunit complexes I–II and III–IV and from I–II and EFTu–EFTs of *E. coli* when incubated as described by Kamen[2], subunit complex I–II does not seem to be inactivated during preparation and storage. Thus it is concluded that, unlike Q_β replicase and its subunit complex III–IV, subunit complex I–II cannot bind ^{3}H-GTP under the conditions used.

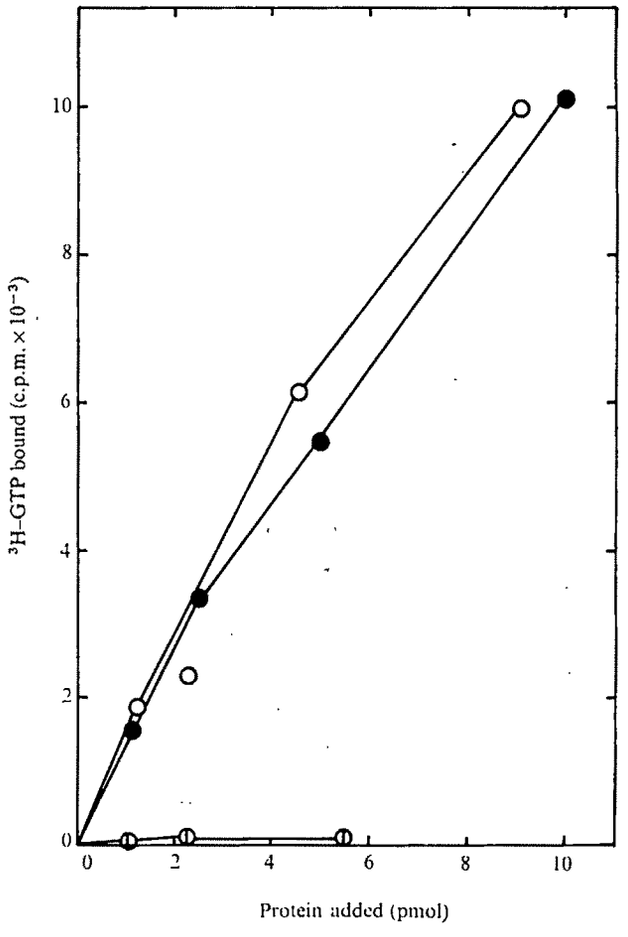

Fig. 2 Comparison of ^{3}H–GTP-binding ability of Q_β replicase and its subunit complexes I-II and III-IV. The complexes were prepared as described in Fig. 1. ^{3}H–GTP-binding was carried out as described in Fig. 1 with various quantities of the replicase (○), subunit complex I-II (Φ) or subunit complex III-IV (●) and 0.22 μCi of ^{3}H–GTP (12 Ci mmol^{-1}). The amount of protein added was calculated by assuming that the molecular weight of enzyme subunits I, II, III and IV are 70,000, 65,000, 45,000 and 35,000 (ref. 2), respectively, and that one molecule of enzyme, subunit complexes I-II and III-IV consist of one molecule each of their respective components.

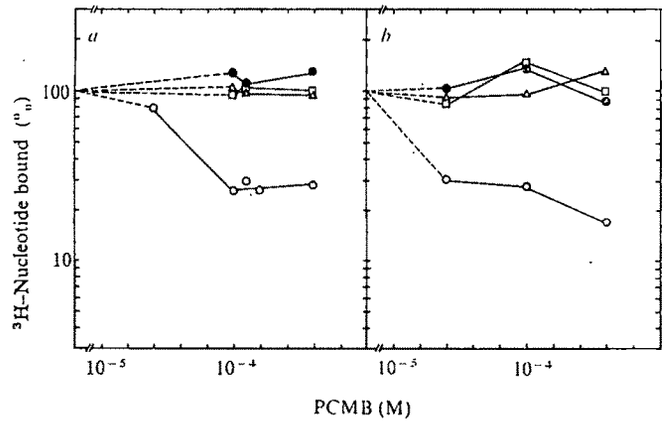

Fig. 3 The effect of PCMB on the binding of ^{3}H-nucleotides to Q_β replicase and its subunit complex III-IV. Q_β replicase and subunit complex III-IV, previously dialysed against 0.05M Tris HCl (*p*H 7.6) containing 0.01M $MgCl_2$ and 20% glycerol were used. The nucleotide-binding assay was carried out for 20 min at 25° C after preincubation of 4.5 pmol of the enzyme (*a*) or 2.5 pmol of subunit complex III-IV (*b*) with the indicated concentrations of PCMB for 10 min at 30° C. In these assays, 0.46 μCi of ^{3}H-ATP (33 Ci mmol^{-1}), 0.35 μCi of ^{3}H-CTP (30 Ci mmol^{-1}), 0.15 μCi of ^{3}H-GTP (12 Ci mmol^{-1}) or 0.49 μCi of ^{3}H-UTP (27 Ci mmol^{-1}) was added to each tube. The amount of ^{3}H-nucleotide bound was measured as described in Fig. 1 and is given as the percentage of the nucleotide bound to enzyme or subunit complex in the absence of PCMB. The amounts of ^{3}H-labelled ATP, CTP, GTP and UTP bound to the control enzyme were 2,558, 2,449, 5,404 and 2,388 c.p.m., respectively, and to the control subunit complex III-IV, 2,612, 1,643, 2,821 and 2,825 c.p.m., respectively. ●, ^{3}H-ATP; △, ^{3}H-CTP; ○, ^{3}H-GTP; □, ^{3}H-UTP.

To localise sites for other nucleotides, I have examined the binding of ^{3}H-ATP, CTP and UTP to these protein components. Each nucleotide reacted with subunit complex III–IV as well as with Q_β replicase (Table 1), although, in either case, bindings of ATP, CTP and UTP were about one order of magnitude weaker than that of GTP. By contrast, significant binding with subunit complex I–II was not observed by either nucleotide-binding assay. These results support the idea that all four nucleotide-binding sites of Q_β replicase are located in subunit complex III–IV rather than I–II. The nucleotide-binding of complex III–IV seems to be somewhat low compared with those of Q_β replicase (Table 1), but can account for about 70% of those of the enzyme. Thus, it seems that subunit complex III–IV needs to interact with other subunit(s) in order to function normally.

Table 1 Binding of ^{3}H-nucleotides to Q_β replicase and its subunit complexes I-II and III-IV

^{3}H-nucleotide added	pmol	^{3}H-nucleotides bound, pmol per pmol protein I-II-III-IV	I-II	III-IV
	2.6	0.05	<0.001	0.03
^{3}H-GTP	5.2	0.09	<0.001	0.06
	13.2	0.18	0.001	0.16
	26.4	0.33	0.002	0.21
	13.2	0.04	<0.001	0.03
^{3}H-ATP	26.4	0.06	<0.001	0.05
	69.0	0.14	0.001	0.12
	139.0	0.29	0.001	0.21
	57.9	0.10	<0.001	0.06
^{3}H-CTP	116.0	0.17	<0.001	0.11
	174.0	0.27	0.001	0.17
	17.9	0.04	<0.001	0.02
^{3}H-UTP	89.0	0.16	<0.001	0.12
	179.0	0.36	0.002	0.21

Q_β replicase and its subunit complexes I-II and III-IV were prepared as described in Fig. 1. The binding assay was carried out for 20 min at 30° C as described in Fig. 1 with ^{3}H-ATP (33 Ci mmol^{-1}), ^{3}H-CTP (30 Ci mmol^{-1}), ^{3}H-GTP (12 Ci mmol^{-1}) or ^{3}H-UTP (27 Ci mmol^{-1}) in the presence of 4.5 pmol of Q_β replicase, 3.84 pmol of subunit complex I-II or 5.0 pmol of subunit complex III-IV. Protein concentration was calculated as described in Fig. 2. The purity of ^{3}H-nucleotides used was estimated to be 99% by paper chromatography.

In an attempt to obtain more information about the nucleotide binding site, the effect of the sulphydryl blocking reagent, *p*-chloromercuribenzoate (PCMB), on nucleotide-binding to the enzyme was examined. PCMB inhibits the enzyme completely at a concentration of 1×10^{-5} M (ref. 19). About 70% of ^{3}H-GTP binding of the enzyme was blocked by 1×10^{-4} M PCMB, whereas the binding of ^{3}H-ATP,CTP and UTP to the enzyme was insensitive to the reagent even at a concentration of 6×10^{-4} M (Fig. 3*a*). A similar correlation was observed with the effect of PCMB on nucleotide-binding to subunit complex III–IV (Fig. 3*b*). These results strongly suggest that there are two different types of nucleotide-binding sites on the enzyme and its subunit complex III–IV; one of which is a PCMB-sensitive site which is of the GTP specific and the other, a PCMB-insensitive site. This possibility is supported in part by evidence that neither ATP, CTP nor UTP interfere with the binding of ^{3}H-GTP to subunit complex III–IV[5]. At present it is still obscure whether the second type of binding site, or PCMB-insensitive site, is common to nucleotides other than GTP and whether PCMB-sensitive GTP binding site is involved, throughout all the processes, in Q_β RNA replication.

Using Q_β replicase with a temperature-sensitive subunit IV, subunit IV has been found to be involved in an early stage of the RNA replication but not in RNA chain elongation when Q_β RNA is the template (my unpublished results). Furthermore, this protein was shown to stimulate specifically the binding of GTP to EFTu–GDP. It is more likely therefore that subunit III *per se* carries binding sites for all four ribunucleoside triphosphates, while subunit IV acts as an effector protein controlling the affinity of nucleotide-binding to the enzyme, particularly the binding of GTP, which is required for initiation of RNA synthesis[20]. As Blumenthal *et al.*[5] pointed out, it is possible that these components in Q_β replicase also take part in a specific interaction with RNA in order to initiate replication since subunit complex III–IV can form complex with Q_β RNA retainable on a membrane filter (unpublished observation).

I thank Dr G. J. Mannering for suggestions. This work was supported in part by grants from the Kudo Science Foundation and the Ministry of Education of Japan.

Effect of ATP on release of intracellular enzymes from damaged cells

THE use of serum enzyme measurements as aids to the diagnosis of disorders of the heart, liver and other organs is established practice in clinical laboratories everywhere, but little is known of the mechanisms whereby intracellular enzymes are discharged from damaged cells. In necrotic states, complete disruption of the cell will lead to release of its contents, but in reversible inflammatory states the cause of the increased membrane permeability remains obscure.

In an attempt to devise a model for the study of the factors affecting the liberation of intracellular enzymes, we recently described the effects of phospholipases A and C, on enzyme release in rat lymphocytes and human leukocytes[1]. In these experiments the porosity of the cell membrane was increased leading to the efflux of cytosolic, and to a lesser extent mitochondrial, enzymes into the medium. We have now investigated the actions of a number of substances which might protect the cell against the effects of phospholipases as judged by a reduction in the leakage of intracellular lactate dehydrogenase. One of these was adenosine triphosphate, ATP, and its effects are described here.

Rat lymphocyte suspensions were prepared in Krebs–Ringer buffer solution (*p*H 7.4) containing glucose (8.3 mmol l^{-1}) and were subjected to phospholipase A as previously described[1]. The experiments were carried out in flasks which were gently shaken in the water-bath (37° C) of a Warburg apparatus. In parallel experiments, ATP was incorporated into the reaction medium 10 min before the addition of the phospholipase. Incubation at 37° C was continued for a further 30 min, after which samples were removed and centrifuged. Lactate dehydrogenase activities were determined in the supernatant and also in sonicated homogenates of the cell suspension to provide an estimate of the total activity. The spectrophotometric method of Wróblewski and LaDue[2] with pyruvate as substrate was used in 25° C.

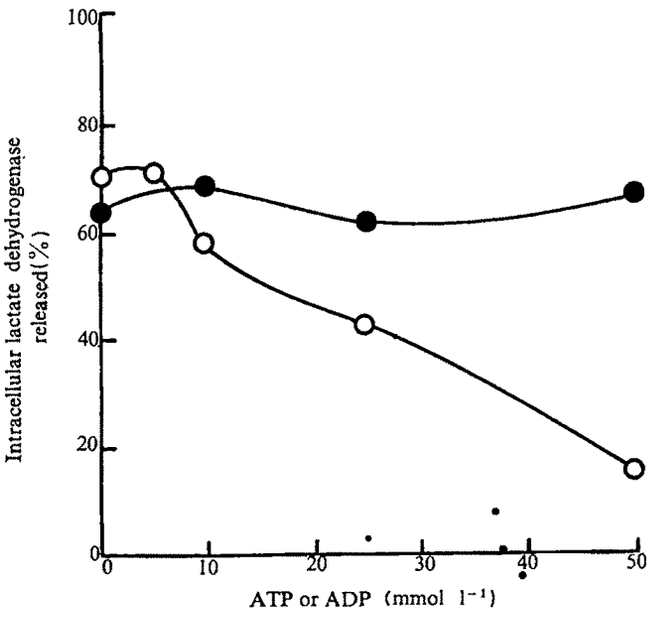

Fig. 1 Effect of ATP (O) and ADP (●) on the leakage of lactate dehydrogenase from rat lymphocytes evoked by phospholipase A (50 mU ml^{-1}).

The results shown in Fig. 1, indicate that at concentrations greater than 5 mmol l^{-1}, ATP reduces the amount of lactate dehydrogenase released from suspensions of rat lymphocytes as the result of the action of phospholipase A. No such effect was observed with ADP in similar concentrations. The protective effect was proportional to the concentration of ATP. In control preparations from which the phospholipase was omitted only small amounts of lactate dehydrogenase were released, and it was uncertain whether ATP exerted a protective effect in these also. We excluded the possibility that ATP had an inhibitory effect on lactate dehydrogenase by demonstrating comparable activities in homogenates containing and omitting ATP, and also by adding ATP to some of the samples during enzyme determination.

Table 1 Effect of ATP on the release of lactate dehydrogenase from rat lymphocytes

ATP concentration (mmol l^{-1})	No. of experiments	Enzyme activity lost from cells (% of control)	
		Mean ± s.d.	Significance
5	7	83 ± 24.9	$P < 0.05$
10	7	74 ± 21.6	$P < 0.005$
50	7	32 ± 19.1	$P < 0.001$

Cells from different rats in each experiment were incubated for 3 h at 37° C in Krebs-Ringer solution (*p*H 7.4).

Similar effects were observed when the output of aspartate transaminase, malate dehydrogenase and glucose 6-phosphate dehydrogenase activities was measured.

A second series of experiments was carried out in which rat lymphocytes were incubated for 3 h at 37° C in the absence of phospholipase A. During this period the intracellular ATP concentration of a control preparation, determined by the method of Adam[3], declined from 1.75 mmol l^{-1} at 30 min to <0.01 mmol l^{-1} after 3 h, and the release of lactate dehydrogenase increased from 15% to 67±s.d. 16%. Incorporation of ATP into the medium led to significant reductions in the enzyme activity lost from the cells (Table 1).

The protective effect ATP in physiologically relevant concentrations observed here is consistent with the view that maintenance of cell membrane integrity is associated in some way with the energy content of the cell. This indicates that any condition which leads to a diminution of intracellular ATP is likely to result in leakage of enzymes and other proteins. Such a relationship was suggested by Sweetin and Thomson[4] to explain their observation that human erythrocytes did not release significant amounts of enzymes until the cells had metabolised all the glucose in the medium. Our work provides experimental evidence in support of this suggestion.

As well as acting as a reserve of energy, ATP may have a direct effect in maintaining the integrity of the cell membrane, as it is known to be concerned in the biosynthesis of phosphatidic acids[5], intermediates in the synthesis of phospholipids, the main components of the membrane. The belief that ATP is almost exclusively an intracellular material and that it cannot enter the cell from extracellular fluids is difficult to reconcile with our findings. The protective action may be associated with a direct effect on the cell membrane or with the uptake of ATP from the medium. We point out that such a process has been observed in rat muscle by Chaudry and Gould[6].

The concept that intracellular enzyme release is secondary to reduction in the ATP content of the cell provides an explanation for the efflux of aldolase from intact rat muscles in response to anoxia, deprivation of glucose and exposure to high potassium ion concentrations reported by Zierler[7]. Glucose is the primary source of ATP synthesis, anoxia leads to accumulation of NADH and failure of the tricarboxylic acid cycle and thus to the inhibition of ATP synthesis, while the high potassium concentration interferes with the action of the Na^+/K^+ pump, the energy for which is provided by the hydrolysis of ATP by ATPase.

Discharge of intracellular enzymes into the circulation occurs in tissue damage due to a variety of causes, such as virus infection, trauma, chemical toxicity, hypoxia, invasion by a malignant process and so on. The suggestion that failure to synthesise ATP in adequate amounts may be a common factor seems to merit further investigation.

Uptake of the neurotransmitter candidate glutamate by glia

GLUTAMIC acid is the primary candidate for a role as an excitatory transmitter at synapses mediating the primary afferent pathway and cortical pathways in mammals[1]. Seeking to gain evidence for this, various laboratories have looked for a mechanism for the efficient removal of glutamic acid from the synaptic cleft. Following the paradigm of monoamine synapses, in which high affinity uptake systems apparently localised in the presynaptic membrane remove transmitter after its action at the postsynaptic membrane[2], high affinity uptake systems for glutamate removal have been sought. Logan and Snyder[3] described a high affinity transport system for glutamate in a synaptosomal preparation, and postulated that it might serve to localise glutamate-mediated synapses. Recent evidence has suggested that the transport systems involved in the removal of putative amino acid transmitters from the synaptic cleft are not localised exclusively in the synapse.

Bulk isolated glial cells have a high affinity uptake system for γ-aminobutyrate (GABA)[4] that seems suitable for participation in the removal of GABA from the synaptic cleft. Autoradiography of a lobster nerve-muscle[5] preparation and rat retina[6] also suggests that GABA is accumulated by glial cells. Similar studies[7] implicated glia in the removal of glycine in spinal cord preparations, glutamate in cortical areas and GABA in the cerebellum.

We have investigated further the ability of glial cells, either obtained as bulk cell fractions or from the C–6 line of cultured rat astrocytoma (given by Dr G. Sato), to accumulate glutamate. We consider that the use of both these preparations can most reliably suggest *in vivo* properties of glial cells: with bulk isolated glia alone there are problems due to cell damage and contamination, and with cultured cells dedifferentiation and the expression of anomalous metabolic properties can be troublesome.

Fig. 1 Positive phase contrast photomicrograph of living rat C-6 glioma cells in normal growth medium 48 h after a 40 h pulse in 10^{-7} M amethopterin. Astroblastic cells soon begin to resemble normal astrocytes. The multipolar processes become very long and develop broad end feet. Bar represents 50 μm.

Bulk isolated glial cell fractions were prepared as described before[4] and were examined by electron microscopy and by the addition of labelled synaptosomes to the initial tissue suspension; both methods indicated less than 10% synaptosomal contamination in the glial fractions. The C–6 clonal line grows in our hands as morphologically differentiated cells, with multiple processes. A 24 h exposure to amethopterin (10^{-7} M) during the third day of logarithmic growth, however, produced cells which appeared to be even further morphologically differentiated (Fig. 1). In addition, the glia-specific protein S–100 increased after amethopterin treatment[9] further indicating that these cells can be induced to express the properties of differentiated glial cells.

Uptake experiments were carried out as described before[3]. Under the conditions used less than 10% of the amino acid is metabolised when examined by paper chromatography. Samples were oxidised in a Packard oxidiser and counted in a Packard liquid scintillation counter. The results are expressed as nmol of substrate accumulated per mg dry weight in 4 min.

The uptake of glutamate by cultured glial cells is illustrated in Fig. 2. Table 1 shows that these results, including the demonstration of high and low affinity uptake systems, correspond remarkably to values reported for the uptake of glutamate by synaptosomal preparations. As a further check on the correspondence between the ability of the synaptosomal fraction to accumulate glutamate and that of the cultured glial cell, the Na^+ dependence of glutamate accumulation was investigated. Solutions containing sucrose or choline chloride were substituted for sodium chloride solutions. The results indicate that the high affinity uptake

Table 1 K_m values for glutamate uptake

Bulk isolated glial cells	$1.2 \pm 0.4 \times 10^{-5}$ M	high affinity
	$1.3 \pm 0.7 \times 10^{-4}$ M	low affinity
Cultured glial cells	$6.6 \pm 1.2 \times 10^{-5}$ M	high affinity
	$1.3 \pm 0.8 \times 10^{-3}$ M	low affinity
Synaptosomal fraction[3]	$3.6 \pm 1.3 \times 10^{-5}$ M	high affinity
	$1.5 \pm 0.9 \times 10^{-3}$ M	low affinity

system was inhibited 81±4% in the presence of choline chloride, while the low affinity system was inhibited 22±3% under identical conditions. This compares with the recently published Na^+ requirement for glutamate uptake by a synaptosomal fraction[10] in which 95.8% inhibition was obtained for the high affinity system.

To evaluate the specificity of the high affinity uptake system two further experiments were performed. The uptake of alanine, a neutral amino acid, was studied in cultured glial cells. A single uptake system was found over the concentration range of 10^{-3} to 10^{-7} M. This system had a K_m of $1.0\pm0.5\times10^{-3}$ M. A line of cultured HeLa cells exhibited only a single uptake system for glutamate, with a K_m of $3.8\pm1.3\times10^{-3}$ M. This suggests that high affinity uptake systems are not involved in the accumulation of all amino acids by glia, and that glutamate uptake mediated by high affinity transport systems is not a general property of other cell types.

To investigate the possibility that glial elements contribute significantly to glutamate uptake by the synaptosomal fraction, it is necessary to show that glia can form small vesicles which can accumulate glutamate. Following a report by Cotman *et al.*[11], we attempted to isolate a gliasome fraction from a sample of cultured cells using the standard Whittaker[12] procedure for isolation of synaptosomes. These

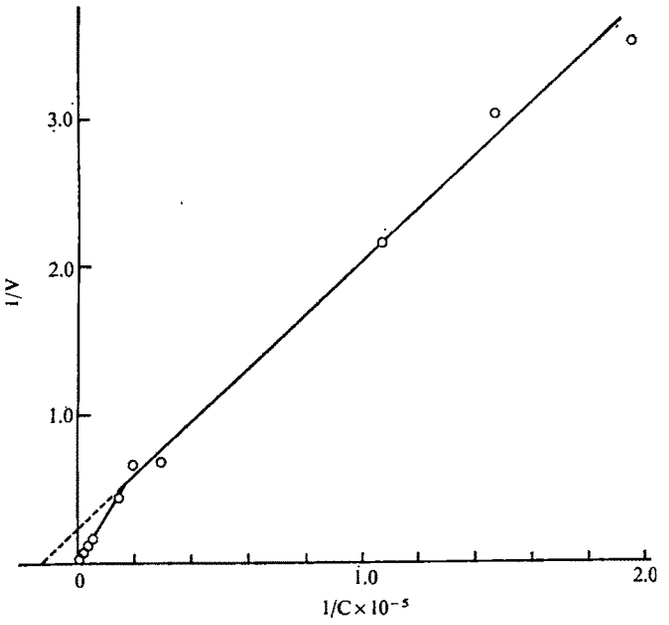

Fig. 2 A double reciprocal plot of the velocity of L-glumatic acid accumulation into glia from the C-6 line of rat glioma at 37°C and varying glumatic acid concentrations. The uptake media contained 140 mM NaCl, 5 mM KCl, 2 mM $MgCl_2$, 3 mM $CaCl_2$, 10 mM dextrose and 10 mM Tris HCl at *p*H 7.4. High affinity $K_m=6.7\times10^{-5}\pm1.3$; low affinity $K_m=1.3\times10^{-3}\pm0.8$.

gliasomes were incubated with 10^{-8} M glutamate and achieved tissue to medium ratios consistently in excess of 24 in 4 min. This uptake was temperature-sensitive and seemed to correspond to the high affinity uptake system characterised in intact cultured cells. This suggests that material isolated by the Whittaker procedure may contain appreciable non-neuronal elements.

Our results indicate that mammalian glial cells, prepared either as a bulk isolated fraction or from the C-6 rat glioma cell culture, have a high affinity transport system for the removal of extracellular glutamate. Glia have also been found to be involved in the uptake of glutamate by the neuromuscular junction of arthropods. This synapse is almost certainly mediated by glutamate[13] and Feeder and Salpeter[14] showed that most labelled cells in an arthropod neuromuscular junction of arthropods. This synapse is cells, a glial element surrounding the synapse. Our demonstration of a high affinity uptake system for glutamate localised in glial cells and the findings of a similar system for GABA in glial cells together with autoradiographic evidence for glial accumulation of these compounds[7] strongly suggests that if these amino acids are neurotransmitters, perisynaptic glial elements are involved in their inactivation.

This investigation was supported by grants from the US National Science Foundation and the Swedish Medical Research Council.

Involvement of brain cholinergic mechanisms in the action of chlorpromazine

THE function of cholinergic neurones in ganglia[1], striatum and other brain areas is normally regulated by dopamine (DA)[2] which, applied microiontophoretically, reduces the increased activity of caudate neurones elicited by acetylcholine[3]. Moreover, DA iontophoresis on caudate neurones mimics the responses elicited by electrical stimulation of the substantia nigra[4,5].

Chlorpromazine and haloperidol, neuroleptics which increase the turnover rate of DA in striatum[6,7], presumably block DA receptor function[8]. Such an action has been credited as an explanation for the antagonism by chlorpromazine of certain behavioural effects induced by amphetamine[9]. It is pertinent to remember that these amphetamine effects are thought to be mediated through the release of transmitter from dopaminergic neurones[10].

* $P < 0.05$ when compared with saline-treated animals.

We have investigated whether the action of chlorpromazine or haloperidol is associated with a change in the activity of brain cholinergic neurones. Since the amount of transmitter synthesised per unit of time is believed to be a good index of its *in vivo* utilisation[11] and since transmitter utilisation may change with neuronal activity[12], we have decided to monitor the effect of chlorpromazine and haloperidol on the turnover rate of acetylcholine (ACh) in occipital cortex and striatum of rats to assess whether when DA receptors are blocked, the synthesis of ACh in various areas of rat brain is increased. We have measured ACh turnover rate in these two brain structures because cholinergic neurones are present in various brain areas and dopaminergic endings are present in neocortex, limbic system, hypothalamic nuclei and striatum[13,14]. However, in striatum a link between the two neuronal systems is suggested by the present understanding of the role of DA in Parkinson's disease.

Tables 1 and 2 show the specific activities of ACh and choline in the striatum and occipital cortex of rates receiving saline, chlorpromazine or haloperidol 1 h before the constant rate infusion of radioactive phosphorylcholine for 6 min. Steady state concentrations of ACh and choline were not changed by the infusion of phosphorylcholine. Moreover, the choline concentrations in the two brain areas studied were comparable whereas the ACh concentrations in

Phosphorylcholine-methyl-^{14}C was infused intravenously at a constant rate for 6 min (30 μCi kg^{-1} min^{-1}). Drugs were injected 1 h before beginning the infusion.
The figures represent the mean values of four experiments ± s.e.m.

Sprague-Dawley male rats (125–150 g) were infused at a constant rate with 0.65 μmol kg^{-1} min^{-1} of phosphoryl choline-methyl-^{14}C (44.0 mCi mmol^{-1}; New England Nuclear Co.) and killed at various times afterwards by microwave radiation focused on the skull (75 mW cm^2). The total power delivered down the wave guide was 1.5 kW at a frequency of 2.45 GHz. We found that when the heads of the rats were exposed to this radiation for 2–3 s, the brain choline and ACh concentrations were stabilised. The brain was dissected and processed for the assay of choline and ACh specific radioactivity as described by Hanin *et al.*[15]. As Fig. 1 shows, the specific activity of striatal ACh and choline increased with infusion time, and the rate of increase proceeded parallel with infusion time in both compounds. The percentage of the ACh store that was renewed per unit of time (fractional rate constant) was estimated at various times of infusion by the finite difference method (ref. 16 and Fig. 1). The fractional rate constant (k) multiplied by the steady state concentration of brain ACh yields an estimation of the amount of ACh made per unit of time.

Brain ACh turnover rate was calculated according to a method described in detail elsewhere[15]. In brief, this method assumes the following kinetic model

where A is the plasma choline compartment, B is the choline compartment in the brain area considered, C is the compartment of ACh in the same area and k_A, k_B and k_C denote the fractional rate constants of A, B and C. respectively. To measure k_C, which is the percentage of ACh pool metabolised per unit of time, and at steady state is equal to the rate of synthesis, the ratio of the specific activity of ACh and choline was calculated at 6 min of infusion and this value was multiplied by the concentration of ACh (in μmol g^{-1}). This value expressed by a given time unit gives an estimate of the turnover rate of Ch.

striatum were three times larger than in occipital cortex. The specific activity of choline in cortex was three times that in striatum, suggesting that each brain area includes several choline compartments. The greater specific activities of choline in cortex than in striatum suggests that the choline compartment that is in rapid equilibrium with blood-borne choline in cortex is smaller than that of striatum. The data presented in the tables also suggest that the brain choline pool that is in rapid equilibrium with the plasma pool is that involved in the synthesis of ACh, because the specific activities of ACh and choline were greater in cortex than in striatum. The amount of ACh synthesised per unit of time was greater in striatum than in cortex: this difference exceeded the three-fold difference in pool size present in these tissues. The amount of ACh synthesised in striatum of rats receiving chlorpromazine (18.6 μmol kg^{-1} intraperitoneally) or haloperidol (10.4 μmol kg^{-1} intraperitoneally) 1 h before the infusion of phosphorylcholine was increased; there was no similar increase in the occipital cortex. These findings minimise the possibility that nonspecific effects of the two drugs are operative in explaining the increase of ACh turnover rate; actually, they suggest that these two drugs affect some neuronal mechanism that is important in the control of striatal ACh synthesis and less important in the control of the synthesis of ACh in occipital cortex. Since these two neuroleptics block striatal dopaminergic receptors[8] and since DA concentrations in striatum are very high[13] the action of haloperidol and chlorpromazine on dopaminergic and cholinergic mechanisms of striatum might be interrelated. A blockade of striatal DA receptors in striatum may account

for the extrapyramidal side effects evoked by the two drugs in several animals species, including man. This possibility is supported by reports that haloperidol is more potent than chlorpromazine in eliciting extrapyramidal side effects[17] and in increasing striatal DA turnover rate (A. Revuelta, personal communication). The finding that chlorpromazine increases the rate of synthesis of brain ACh is in keeping with a report by Stadler *et al.*[18] showing that chlorpromazine increases the release of ACh from the perfused striatum of rats. Chlorpromazine is credited for exciting an inhibitory action on cholinergic receptors when given in large doses.

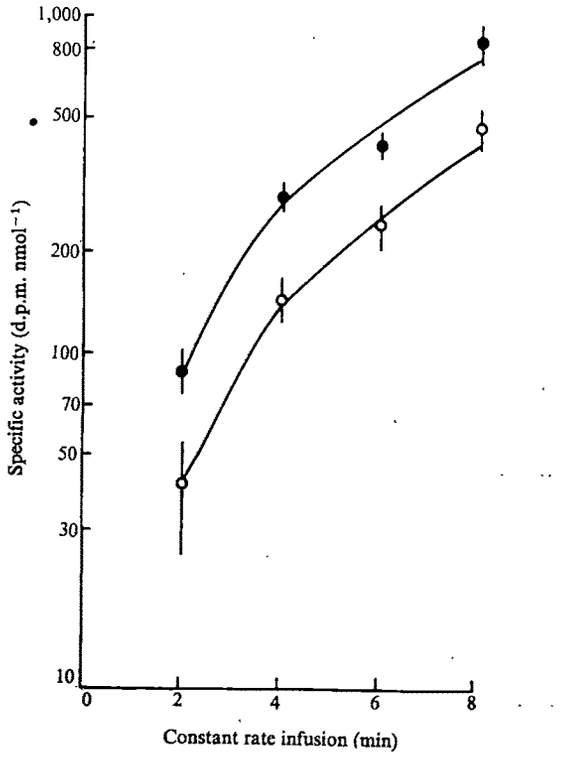

Fig. 1 ACh (○) and choline (●) specific radioactivities in rat striatum after phosphorylcholine(methyl-^{14}C) (30 μCi kg^{-1} min^{-1}) was infused for various minutes and the rats were killed immediately after microwave irradiation.

$$* k_{ACh} = 2\,(S_{Ach\ t2} - S_{Ach\ t1})/\Delta_t\,(S_{ch\,t1} - S_{Ach\,t1} + (S_{ch\,t2} - S_{Ach\,t2})$$

Δmin	$*k_{ACh}$
3-2	0.44
4-3	0.42
5-4	0.34
6-5	0.32
7-6	0.31
8-7	0.32

Such an action cannot explain the increased synthesis of striatal ACh elicited by chlorpromazine because haloperidol, which is more active than chlorpromazine in stimulating the synthesis of ACh, is less active in blocking cholinergic receptors[17]. Similar considerations can be made to exclude the fact that the anticholinesterase action of chlorpromazine is involved in the stimulation of striatal ACh synthesis[17]. In interpreting the physiological implications of the increase of ACh synthesis rate reported in the Tables, it would be important to know whether an increase of striatal ACh synthesis corresponds with an increase in the activity of cholinergic neurones. A direct answer to this question cannot be given at this time because the correlations between ACh turnover rate and the firing rate of cholinergic neurones has not been studied directly. Presumptive indirect evidence, however, supports the belief that the rate of ACh synthesis reflects the activity of cholinergic neurones (D. Cheney and M. Trabucchi, unpublished work).

Finally, it would be interesting to establish whether this increase of ACh synthesis in striatal cholinergic neurones is required to elicit an antipsychotic action. We are currently working to explore several factors involved. We found that clozapine, a neuroleptic with antipsychotic activity comparable with chlorpromazine but lacking the extrapyramidal side effects[19], fail to increase the rate of ACh synthesis in striatum. Although, the present level of understanding would indicate that the increased biosynthesis of striatal ACh relates to the extrapyramidal side effects of neuroleptics rather than to their antipsychotic properties, more work is needed to reach a definite conclusion on this point.

Effect of histamine H-receptor blockade on fasting serum gastrin and fasting gastric acid secretion in the dog

Histamine receptors which are blocked by conventional antihistamines, such as mepyramine maleate, have been termed H_1-receptors. Receptors which are not blocked by these drugs have been found in the cardiac atrium, the uterus and the gastric parietal cell[1] and have been termed H_2-receptors. An antagonist of these receptors (burimamide) has recently been discovered[2]. Histamine H_2-receptor antagonists inhibit gastric acid secretion stimulated by

histamine, pentagastrin, hypoglycaemia and food in the dog (M. I. Grossman and S. J. Konturek, unpublished) and by histamine and pentagastrin in cat (S. J. Konturek, unpublished), pig (G.O.B., M. W. Waterworth, M. D., and S. B., unpublished), and man[3]. Studies have shown that some hormonal inhibitors of gastric acid secretion, namely secretin[4] and glucagon[5,6], depress fasting serum gastrin levels in man and a common mechanism of action through suppression of gastrin-mediated acid release has been postulated. This study attempts to determine whether burimamide has any effect on gastric acid secretion and gastrin release in basal conditions in the dog.

Two mongrel dogs weighing 17 and 25 kg were prepared with gastric fistulae, and subsequent studies were performed at least 3 months after surgery. Not more than one experiment was carried out every 48 h, and dogs were fasted for 16 h before each study. Gastric juice was collected every 15 min for 1.25 h after gastric collections had reached basal levels. After the first 15 min injections lasting 60 s of either burimamide (8 mg per kg body weight in a solution containing 15 mg ml^{-1}) or 0.15 M NaCl ml^{-1} were given into a leg vein. In both dogs burimamide injections

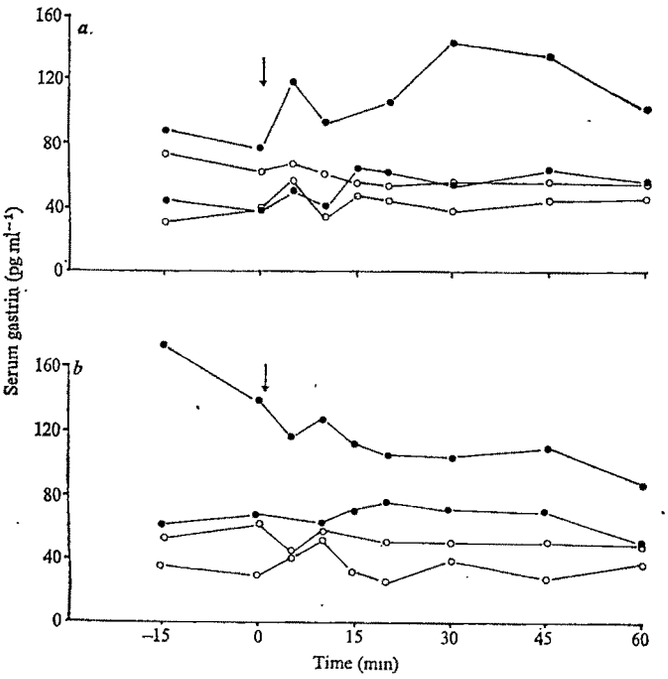

Fig. 1 Serum gastrin concentration in pg ml^{-1}. Burimamide (*a*) or saline (*b*) was injected at time 0. Open or closed circles denote studies performed in the same animals.

were followed by retching and restlessness which subsided within 2–5 min. Blood was taken from a separate leg vein 15 min before and 0, 5, 10, 15, 20, 30, 45 and 60 min after test injections. The blood was allowed to clot, and the serum separated and stored at −20° C. Gastrin was estimated later by radioimmunoassay (A. V. and B. G., unpublished). Gastric juice was measured to the nearest 0.5 ml and the acid titrated against 0.2 M NaOH using an automatic titrator (Radiometer, Copenhagen). Two burimamide and two control studies were performed in each dog in random order.

Figure 1 shows the serum gastrin concentrations in the four saline and the four burimamide-treated animals. In three test and four control studies there was minimal variation in serum gastrin concentrations from basal levels. A slight rise in serum gastrin levels occurred in only one test following burimamide. The differences between control and burimamide tests were not significant.

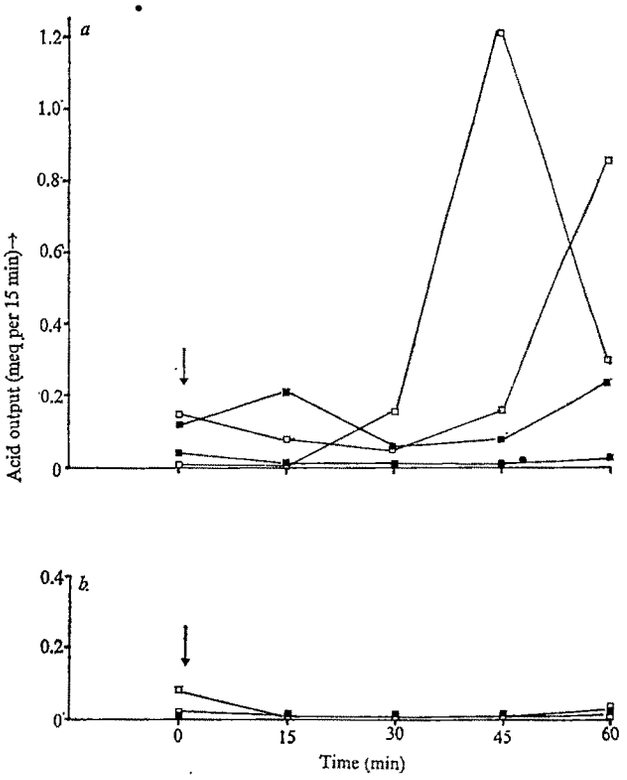

Fig. 2 Acid output from gastric fistulae in meq per 15 min. Burimamide (*a*) or saline (*b*) was injected at time 0. Open or closed squares denote studies performed in the same animal.

Two of the four dogs studied showed a slight rise in gastric acid secretion (Fig. 2) from 30–60 min after burimamide. The rise was, however, small in terms of output of acid, reaching a maximum of 1.20 and 0.72 meq per 15 min over basal levels in the two dogs. Dogs receiving control saline injections showed no increase in acid output.

The results of this study show that serum gastrin levels are not altered by burimamide given intravenously to fasting dogs. The reduction in acid secretion observed with burimamide is unlikely to be a consequence of lower levels of circulating gastrin. The slight rise in serum gastrin after burimamide in one study may be a secondary phenomenon following a slight reduction in gastric acidity and deinhibition of the antrum.

In searching for a unifying mechanism linking gastric acid secretion and gastrin release, earlier studies demonstrated that secretin[7] and glucagon[8] both inhibit gastric acid secretion, and they both depress fasting serum gastrin levels[4–6]. In this respect they differ from H_2-receptor antagonists. Differences between the action of secretin and burimamide are amplified by studies on histidine decarboxylase in rat gastric parietal cells. Whereas secretin does not stimulate histidine decarboxylase in the rat[9] recent studies have shown that both burimamide and metiamide produce a 3–5-fold rise in histidine decarboxylase levels in rat glandular stomach[10]. The compound SC 15396, an antigastrin, also produces a rise in histidine decarboxylase in the rat[11,12] while inhibiting gastric acid secretion stimulated by both histamine and gastrin[12]. It is thought that this antigastrin acts at the gastrin receptor site on the parietal cell[11]. There is no evidence to support the concept that H_2-receptor antagonists inhibit gastric acid secretion by acting outside the parietal cell. It is, however, possible that histamine and gastrin act on different receptors on the same cell as postulated by Grossman and Konturek.

The late rise in gastric acid secretion following burimamide in two studies, although small in terms of milliequivalents of acid, was clearly not seen after the control

injections. Since the duration of action of burimamide given intravenously is short in both dogs (M. I. Grossman and S. J. Konturek, unpublished) and pig (G.O.B., M. W. Waterworth, M.D., and S.B., unpublished), the late rise in acid release may be the result of 'rebound' following withdrawal of the inhibitor. This phenomenon is known after certain calcium containing antacids[13], and it would be clinically relevant if this phenomenon occurs when H_2-receptor antagonists are used therapeutically in man.

This study was supported by the Medical Research Council of South Africa. Synthetic human gastrin and related peptides used in the radioimmunoassay were donated by Dr J. Morley of Imperial Chemical Industries, Macclesfield, UK. Burimanide was donated by Dr W. A. M. Duncan of Smith, Kline and French.

Cone mechanisms initiating response of on–off goldfish optic fibres

On–off ganglion cells are common in a wide variety of vertebrate retinae[1], including those of primates (F. M. de Monasterio and P. Gouras, personal communication). These units respond with a short, high-frequency burst of action potentials when a stationary light is turned on in the receptive field and also when the light is turned off. Because a dark or light spot moving across the receptive field elicits a vigorous response, Maturana *et al.*[2] called on–off units in the frog "moving contrast detectors".

I have explored the properties of on–off fibres in the goldfish optic nerve. The generation of the on–off response in goldfish is of special interest because the goldfish retina has three classes of cones with peak sensitivity at 620, 530 and 455 nm (ref. 3), and the majority of ganglion cells give a colour-coded response[4]. I shall show that on–off fibres are a separate class of fibres with properties quite different from those of colour-coded units. I have determined the contribution of each of the three cone mechanisms in initiating the on and off components of the on–off response.

Common goldfish, *Carassius auratus*, were anaesthetised with tricaine during surgical exposure of the optic nerve, and were then immobilised with curare for the duration of the experiment. Tungsten microelectrodes coated with Insl-x were inserted into the optic nerve and the activity picked up from single fibres was amplified, displayed and tape recorded. The optical stimulation of the eye has been described in detail elsewhere[6]. The left eye of the fish was under water and at the centre of a 24-inch diameter plastic hemisphere filled with water. Stimuli were presented on a back-projection screen taped to the surface of the hemisphere being observed by the fish. The stimuli and coloured backgrounds which were projected on to the back-projection screen originated in high intensity Prado projectors fitted with electronic shutters and frames for holding neutral density filters, narrow band interference filters and interference cutoff filters.

Results were obtained for 16 on–off fibres in a total sample of 73 fibres. This is a higher percentage (22%) of on–off units than

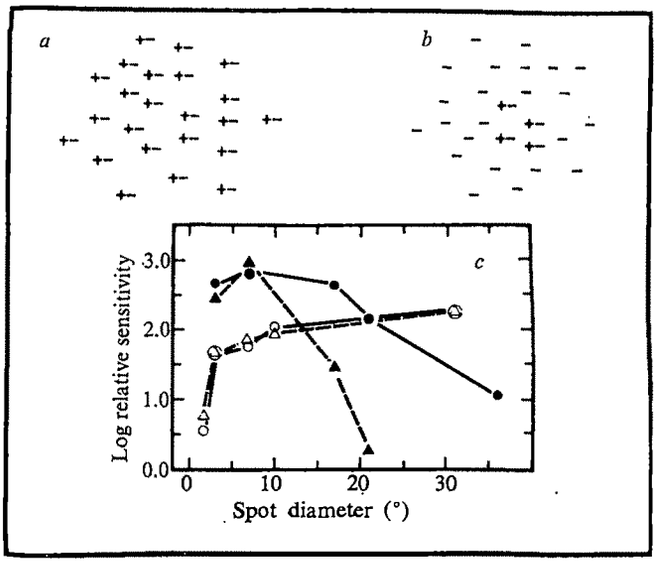

Fig. 1 Receptive field characteristics of on–off fibres. *a*, On–off receptive field centre having both on and off responses across the centre. The centre, about 20° in diameter, was mapped with a 1° spot 2.4 log foot-lambert in brightness. *b*, On–off receptive field centre having both on and off components at the midpoint, but only the off component towards the periphery. The width of the receptive field was about 10° mapped with a 2°, 1.8 log foot-lambert spot. *c*, Influence of spot size on sensitivity of the on (●○) and off (▲, △) components of the response. ▲, ●, An on–off fibre having an inhibitory surround which, for spot sizes above 10° in diameter depressed the sensitivity of both on (●) and off (▲) centre components. ○, △, An on–off unit which showed no reduction in sensitivity of the on (○) or off (△) centre response with larger spot sizes.

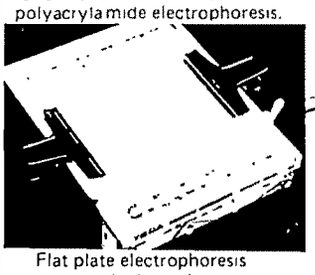
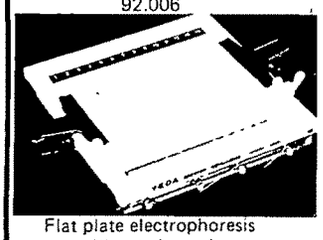


has been reported in a different preparation, the isolated goldfish retina (6%) (ref. 4). I established that both the on and off responses originated in a single optic fibre by showing that photographed action potentials in the on and off bursts had the same height and waveform.

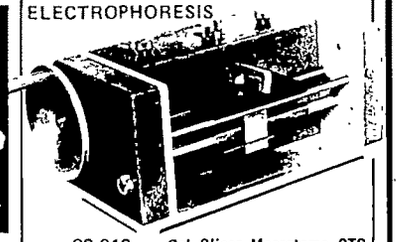
Since stimulation of colour-coded receptive fields can result in an on–off response under certain conditions, I explored the receptive field of on–off units with stationary small spots of white light 1° or less in diameter. Neither the on nor the off components of the response were isolated in a central region of the receptive field. Either both on and off responses were present across the receptive field (Fig. 1*a*), or one or the other of the components dropped out at more peripheral receptive field positions (Fig. 1*b*). Both types of receptive field were quite different from the centre-surround, double-opponent organisation of colour-coded units[4]. The units described here were not directionally sensitive, a feature often associated with the on–off response in other animals. In goldfish optic nerve directionally sensitive fibres are present in small numbers[5].



YEDA SCIENTIFIC INSTRUMENTS
Rehovot, Israel

A COMPLETE LINE OF INSTRUMENTATION FOR ANALYTICAL AND PREPARATIVE ELECTROPHORESIS AND RAPID FILTRATION OF MACROMOLECULES.

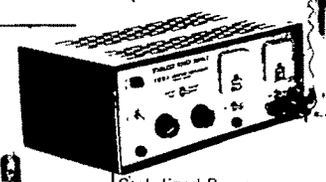
A set of instruments for one and two dimensional polyacrylamide electrophoresis.



Flat plate electrophoresis with channels 92.006

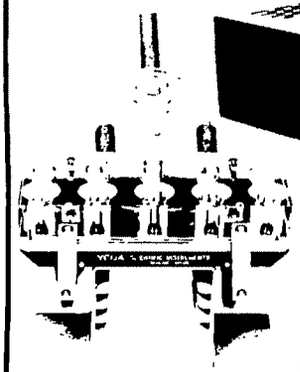
Flat plate electrophoresis without channels 92.007

A COMPLETE SET OF COMPACT INSTRUMENTS FOR POLYACRYLAMIDE DISC GEL ELECTROPHORESIS



92.012 – Gel Slicer Macrotome GTS

Preparative gel electrophoresis Isolates up to 100 mg. of proteins and nucleic acids.



Electrophoretic Extractor 92.009

Stabilized Power Supply 92.003

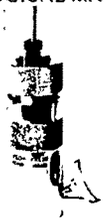
Separation Chamber 92.009

An instrument for rapid processing of a large number of radioactive samples.

Multiple Membrane Filter 92.051

PLASTIC ONE-PIECE CANNULAS

Infusion Cannula: 92.103A



Injection Cannula: 92.103B

DEVICES FOR BREAKING BIOLOGICAL MATERIAL

YEDA PRESS

compressed gas from a standard pressure tank is applied, and the cells are broken due to sudden decompression.

92.050

TISSUE CHOPPER

For maceration of soft, highly hydrated multicellular material.

92.011

CHARLES C THOMAS • PUBLISHER

LECTURES ON THE PHENOMENA OF LIFE COMMON TO ANIMALS AND PLANTS. Volume I *by* **Claude Bernard,** *Former Professor, College de France and Museum d'Histoire Naturelle, France. Translated by* **Hebbel E. Hoff, Roger Guillemin** *and* **Lucienne Guillemin,** *all of Baylor Univ., Houston, Texas.* This work is Professor Bernard's basic statement on the philosophy, the problems and the future of general physiology. *'74, 336 pp., 80 il., $12.95*

BIOLOGIC AND CLINICAL EFFECTS OF LOW-FREQUENCY MAGNETIC AND ELECTRIC FIELDS *by* **J. G. Llaurado, A. Sances, Jr.,** *and* **J. H. Battocletti,** *all of the Medical College of Wisconsin, Milwaukee. (50 Contributors)* Arranged in five sections, this book examines the state of current knowledge with regard to the effects of static and slowly-changing magnetic and electric fields on communication processes in humans, animals and plant life. *'74, about 383 pp. (6 3/4 x 9 3/4), 130 il., 36 tables*

TOXICOLOGY AND PHARMACOLOGY OF VENOMS FROM POISONOUS SNAKES *by* **John H. Brown,** *Louisiana State Univ., New Orleans.* This book offers the only comprehensive review in simplified form of poisonous snakes, their names, specific localities, the toxicity and pharmacology of their venoms, the amount of venom they can inject in a bite, and the factors determining this. *'73, 208 pp., 72 il. in full color, cloth-$13.75, paper-$9.95*

LIVING CLOCKS IN THE ANIMAL WORLD *by* **Miriam F. Bennett,** *Colby College, Waterville, Maine.* This text discusses the investigations of the biochronometers of crabs, bees, worms, molluscs and amphibians, and is written for biologists and other scientists who are interested in timing phenomena in organisms and the relationships of environmental factors to living clocks. *'74, 236 pp., 53 il., $11.75*

CHROMOSOMES IN HUMAN CANCER *by* **Jaroslav Cervenka,** *Univ. of Minnesota, Minneapolis, and* **Lucien Koulischer,** *Institut de Morphologie Pathologique, Loverval, Belgium. Edited by* **Robert J. Gorlin,** *Univ. of Minnesota, Minneapolis.* The aim of this monograph is to contribute to a better understanding of the seemingly disordered chromosomal constitution in human cancer cells and of the few rules which might be derived from this data. *'73, 212 pp., 23 il., 37 tables, $13.75*

PINEAL CHEMISTRY: In Cellular and Physiological Mechanisms *by* **W. B. Quay,** *Univ. of Wisconsin, Madison.* Written for biomedical investigators, practitioners and teachers, this monograph reviews mammalian and human pineal chemistry with emphasis on physiological correlations and interpretations. *'74, 448 pp., 91 il., 91 tables, $24.75*

MERCURY, MERCURIALS AND MERCAPTANS. *Edited by* **Morton W. Miller** *and* **Thomas W. Clarkson,** *both of The Univ. of Rochester, Rochester, New York. (33 Contributors)* Current, relevant research in the areas of biological effects and mercury-related compounds are critically analyzed. Dose response relationships in man and the action of mercury and its compounds on life processes are covered. *'73, 404 pp., 116 il., 57 tables, $19.75*

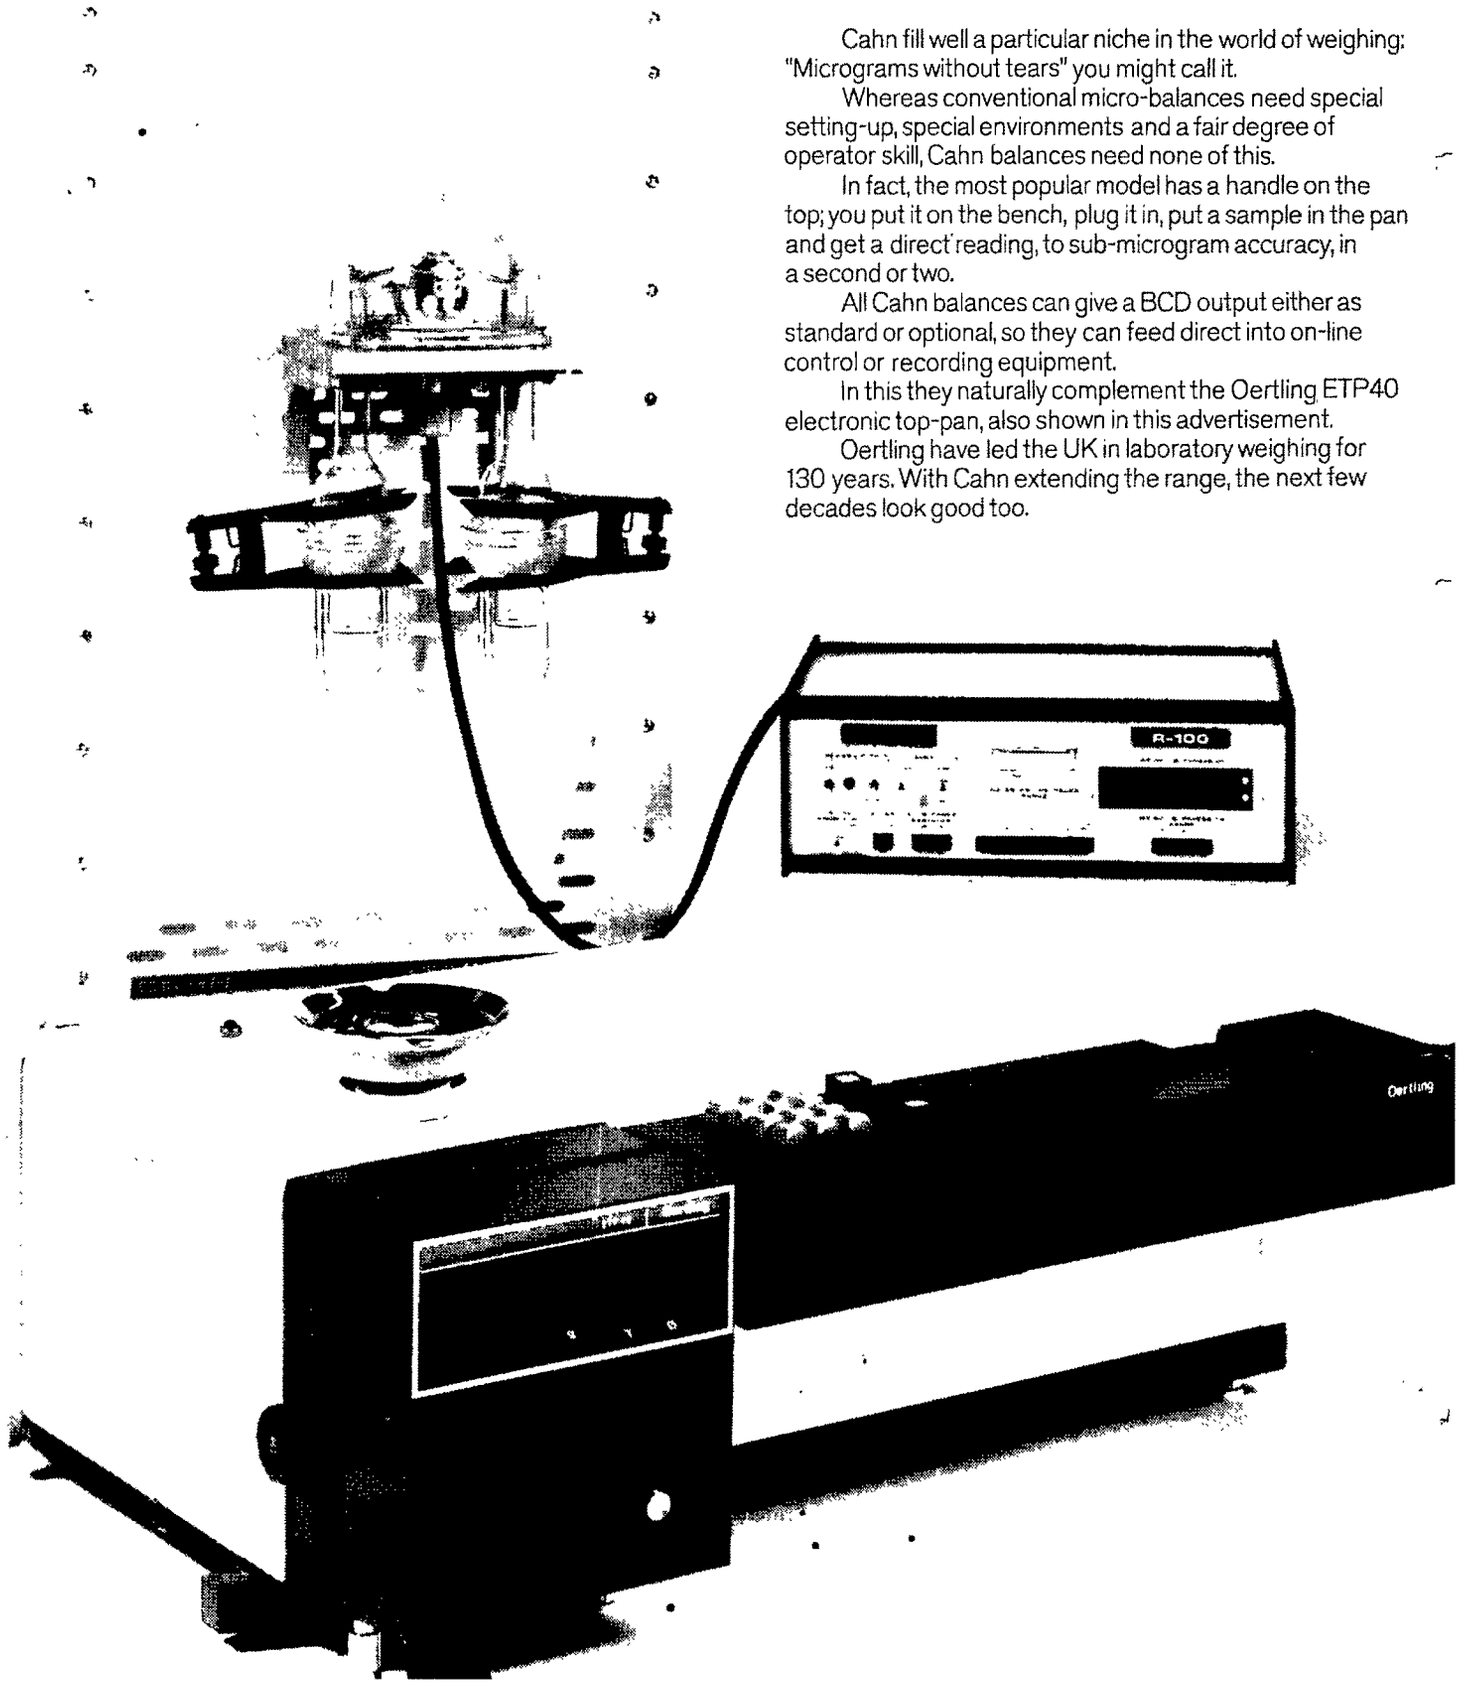
Oertling + Cahn

We are pleased to tell you that Oertling have taken over the sole UK Agency for Cahn Instruments, of Paramount, California.

Cahn fill well a particular niche in the world of weighing: "Micrograms without tears" you might call it.



Whereas conventional micro-balances need special setting-up, special environments and a fair degree of operator skill, Cahn balances need none of this.

In fact, the most popular model has a handle on the top; you put it on the bench, plug it in, put a sample in the pan and get a direct reading, to sub-microgram accuracy, in a second or two.

All Cahn balances can give a BCD output either as standard or optional, so they can feed direct into on-line control or recording equipment.

In this they naturally complement the Oertling ETP40 electronic top-pan, also shown in this advertisement.

Oertling have led the UK in laboratory weighing for 130 years. With Cahn extending the range, the next few decades look good too.

weighing family.

R100 Recording Electrobalance R

Top left, with weighing mechanism in the symmetrical glass envelope, control module alongside, and optional pen recorder (below).

High capacity, 100g.

Sensitivity, 0.5µg.

Rapid response, to weighing in vacuum up to 10^{-6} torr, or under controlled atmospheres, including corrosive gases.

With push-button range selection, push-button taring, a panel meter to read sample weight and weight change, and an automatic range extender covering up to ten chart widths.

A special RG version is also available with a large range of accessories for TGA, absorption work, magnetic susceptibility, particle size analysis, density measurement etc.

4100 Manual Electrobalance

This page, centre.

The most popular Cahn model; a direct reading micro-balance that can give a complete reading in a few seconds.

No wonder it's used for Lunar dust, air pollution samples, etc. etc.

Robust, portable and very easy to use. Just put the sample on the pan.

Capacity, up to 2.5g.

Four weight ranges, 2mg, 20mg, 200mg and 10000mg.

Sensitivity on 2mg range, 0.1µg.

4-digit electronic display read-out, with 100% over-range, i.e. up to 19999.

Automatic decimal position, with no chance of misreading. BCD output for computer or optional Cahn printer.

Models GR M and G-2, without digital display, also available at lower cost.

DTL Toploading Electrobalance

Below.

A very versatile direct-reading balance, with large three-digit electronic display

Capacity 10g.

Sensitivity 0.1mg (0.01mg optional)

Two weight ranges, 100mg and 1000mg

0-10 volt analog output for recorder or DVM, with BCD optional.

Up to 15 samples per minute can be weighed, in all kinds of hot, dry or adverse environments; once the sample is on the pan you can get a reading in as little as half a second.

Also available, as RTL without electron display.

Oertling ETP40

Opposite, bottom left.

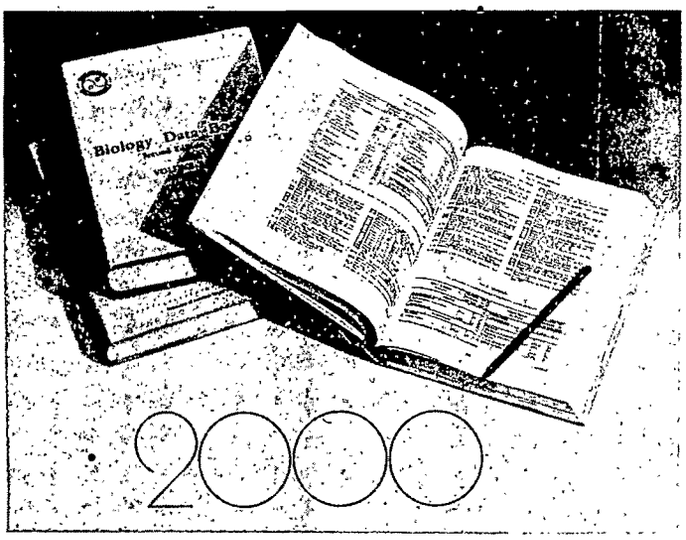
The special electronic version of the celebrated Oertling top-pan analytical balance, developed from the CoID award-winning TP30.

Capacity 800g + 100g tare.

Sensitivity 10mg.

Scale range 100g.

Large 5-figure digital display, plus BCD output and optional 10-key mosaic printer (shown right of balance) to code samples with batch number, time, date etc. on paper record.



Currently used in fine chemical production, biochemical research, precious metal weighing etc.

Oertling sales staff are now giving special demonstrations of all Cahn equipment, on customers' premises, and Oertling maintenance engineers have been fully trained to give all necessary service.

You will find more than 2000 pages of reference data in FASEB's new three-volume BIOLOGY DATA BOOK, the greatly expanded and fully updated successor to the 1964 single-volume handbook of the same title. Some 750 distinguished scientists have contributed and verified the material in the 282 tables. Explanatory headnotes introduce most tables, and over 17,000 references identify the original data sources. To assure instant access to any item of information, 200 pages of extensive cross-indexes have been provided. In selecting, evaluating, checking, and rechecking the material which constitutes this 2,000-page "library", every effort has been made to meet your need for current, reliable, reference data in the life sciences.

The BIOLOGY DATA BOOK is available, either on a single-volume basis or as a complete set. Volumes I and II are ready for immediate shipment. Volume III is nearing completion and orders will be filled, starting on or about 1 August 1974.

SAVE $15.00—SPECIAL PRE-PUBLICATION OFFER
Valid only to 1 August 1974

If your order for the complete three-volume BIOLOGY DATA BOOK is placed prior to 1 August 1974, it will be accepted at the postpaid price of $75.00—less by $15.00 than the regular per-volume price of $30.00. Take advantage of this 16-2/3% saving by placing your order—TODAY.

BIOLOGY DATA BOOK

VOLUME I (1972)
606 Pages, 71 Tables, 6110 References, 9 Appendixes

I. Genetics and Cytology (136 pp, 1557 refs)
II. Reproduction (36 pp, 519 refs)
III. Development and Growth (74 pp, 636 refs)
IV. Properties of Biological Substances (166 pp, 2796 refs)
V. Materials and Methods (83 pp, 523 refs)
Appendixes (46 pp, 79 refs)

ISBN: 0-913822-06-X

VOLUME II (1973)
845 Pages, 96 Tables, 5970 References

VI. Biological Regulators and Toxins (174 pp, 1808 refs)
VII. Environment and Survival (272 pp, 2333 refs)
VIII. Parasitism (73 pp, 305 refs)
IX. Sensory and Neurobiology (181 pp, 1524 refs)

ISBN: 0-913822-07-8

VOLUME III (1974)
Approx. 550 Pages, Approx. 115 Tables, Approx. 5140 References

X. Nutrition, Digestion, and Excretion (Approx. 93 pp, 1246 refs)
XI. Metabolism (Approx. 42 pp, 394 refs)

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, **'Molecular Biology Comes of Age'** looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.
Reprints of **'Molecular Biology Comes of Age'** are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

Circulation Department, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me.....copies of **'Molecular Biology Comes of Age'**, by surface mail/airmail (delete whichever is not applicable).

I enclose £.....

Area-threshold curves confirmed a previous finding in the frog[6] that the excitatory on–off centre may have around it an inhibitory surround which raises the threshold for on and off components of the centre response (Fig. 1*c*, closed circles). In some cases, an inhibitory surround was not present (Fig. 1*c*, open circles). No response has been noted following stimulation of the surround alone. Within the on–off central region, there was an increase in sensitivity with larger stimulus sizes.

The cone mechanisms responsible for the on and off components were identified by making spectral sensitivity measurements. An example of the results is shown in Fig. 2. On–off responses were obtained to all monochromatic stimuli of 1 s duration at wavelengths from 400–720 nm. The thresholds for the on and off components were similar in this unit, although this was not always the case. Against a white background (Fig. 2*a*), both the on and off thresholds for responses above 500 nm fitted the retinene-2 nomogram of the red-absorbing goldfish pigment peaking at 620 nm. For 500 nm stimuli and below, the thresholds fell on the retinene-2 nomogram for the blue-absorbing cone pigment with peak sensitivity at 455 nm. A green mechanism on–off response was not evident against a white background but became apparent against a magenta background which reduced the red and blue mechanism sensitivities (Fig. 2*b*). The on and off thresholds against the magenta background for wavelengths between 500 and 620 nm fell on the retinene-2 nomogram for the green-absorbing cone pigment peaking at 530 nm.

Figure 2 shows that both the on and off response at a given wavelength are elicited by the same set of cone receptors, sensitive to red, green or blue. In the goldfish this was by no means a foregone conclusion, since on and off could have been elicited by different cone receptor types. As is true with colour-coded goldfish optic fibres[6], a single on–off optic fibre may receive connections from all three receptor systems. Only a few examples have been noted where one of the three cone systems could not be identified with the use of coloured adapting backgrounds. The strong blue mechanism response illustrated in Fig. 2 is characteristic of many optic fibres recorded from the intact, curarised goldfish[6]. The finding is somewhat puzzling in view of the failure of experiments using the isolated goldfish retina to see a blue mechanism response[4,7] and of Mark's report[3] that less than 7% of a sample of 113 goldfish cones contained blue-absorbing pigment. The spectral sensitivity curves of on–off fibres differ from those of colour-coded units in that there is no evidence of opponent interaction between red and green mechanisms. In colour-coded units this interaction tends to narrow opposing shoulders of the red and green mechanism spectral sensitivity curves at intermediate wavelengths where both red green mechanisms are stimulated simultaneously[4].

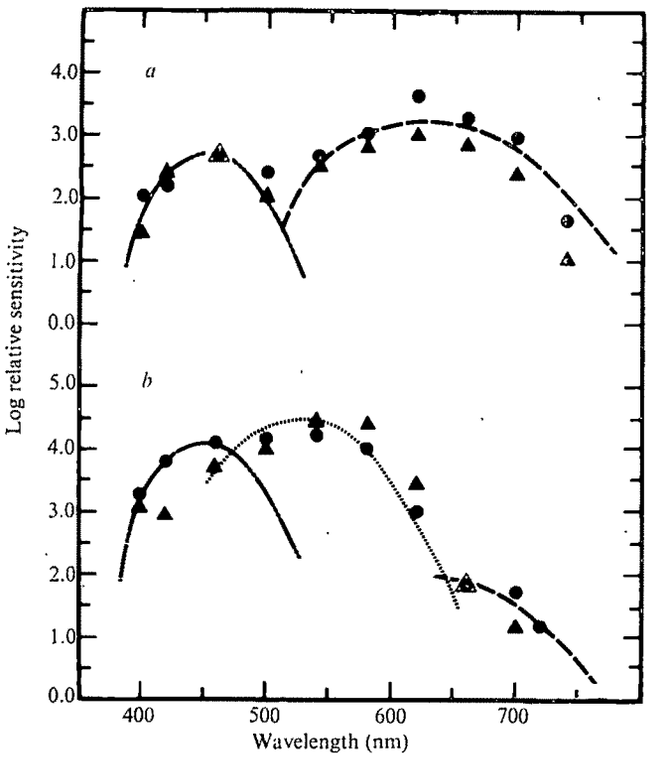

Fig. 2 Spectral sensitivity curves for an on–off unit: on response sensitivity (●) and off response sensitivity (▲). *a*, Curve measured against a 0.1 log foot-lambert white background. *b*, Curve measured against a magenta background made by superimposing a red-adapting background from a 650 longwave pass filter in a 1.7 log foot-lambert beam and a blue-adapting background from a 450 shortpass filter in a 0.6 log foot-lambert beam. The lines are retinene-2 nomograms for goldfish cone pigments having peak sensitivities at 620 nm (— — —), 530 nm (. . . . . .) and 455 nm (—. .—. .—. .—). The spectral sensitivity curves indicate that both on and off responses are given by all three cone mechanisms.

I examined the latency and number of spikes for the on and off components of the responses as a function of intensity. For all wavelengths, and hence for all three cone mechanisms, there was a decrease in the latency of both on and off responses as intensity increased in 0.5 log unit steps above threshold. Occasionally, at the highest intensities, the off threshold would show a slight increase in latency. In general, the number of spikes in the on and off burst increased only slightly or not at all with increase in the stimulus intensity. This feature of the response indicates that on–off units would not have the dynamic frequency range necessary of a separate brightness channel. This in turn suggests that colour-coded fibres must carry both hue and intensity information in the same channel or that a separate class of brightness fibres, not yet encountered, exists in the goldfish.

The retinal pathways which synthesise the optic fibre on–off response are incompletely understood. Stimulation of horizontal cells in turtle retina can lead to an on–off ganglion cell response[1]. But no on–off response from cells clearly identified as being bipolar has been reported. Two types of bipolar response, on-centre and off-centre, have been noted in goldfish[9] and carp[10]. Hence the ganglion cell on–off centre response must originate in one of two ways: (1) the convergence of on- and off-centre bipolars at the ganglion cell or (2) ganglion cell connections from on–off amacrine cells. Both bipolar-ganglion cell and amacrine cell-ganglion cell connections have been noted in the inner plexiform layer of carp[11]. If the first alternative is correct, then both the on- and off-centre bipolar types probably make excitatory connection with the on–off ganglion cell. In the tetrodotoxin-treated frog retina, the on–off ganglion cell response results from two depolarisations of the ganglion cell at onset and termination of light stimulation, with no intervening hyperpolarisation[12]. The second alternative origin of the ganglion cell on–off response is attractive because on–off amacrine cells have been identified in the carp. Toyoda *et al.*[13] classified the response of 178 carp amacrine cells and found 42 or 24% which were on–off, giving a depolarisation at both the onset and termination of stimulation. This is close to the proportion of optic fibres I found to be on–off. The on–off amacrine cell is a logical candidate to provide the major input to on–off ganglion cells. This is especially true in goldfish retina where the remaining ganglion cells have colour coded, double opponent receptive fields in which a role for on–off amacrine cells is difficult to envisage.

This work was supported by the Medical Research Council (Canada). I thank Mrs Vrablic for technical assistance and Drs Daw and Gouras for reading the manuscript.

Genetic variation in marine fishes as a test of the niche-variation hypothesis

SINCE the discovery of large and variable amounts of protein polymorphism in natural populations[1], biologists have attempted to determine what, if any, biological significance is associated with this particular form of phenotypic variation. Many population geneticists and ecologists[2-5] have adopted a selectionist point of view which states that allelic diversity is a strategy for increasing population fitness in a temporally and spatially heterogeneous habitat. This hypothesis, known as the "niche-variation hypothesis", predicts a positive correlation between the protein polymorphism and morphological variation in a population and the relative heterogeneity of the most relevant physical (for example, temperature) and biological (for example, food and competition) variables of the habitat. The basic assumption underlying this hypothesis is that the presence of more than one variant of a given protein broadens the tolerance limits or the optimal functioning range of the structures and/or reactions associated with the protein. For example, the presence of multiple forms of an enzyme, each with a different thermal optimum, may broaden the thermal tolerance range of an ectothermic (poikilothermic; cold blooded) organism[6].

Though here we are primarily concerned with testing the niche-variation hypothesis, it must be kept in mind that there are other selectionist explanations for the observed patterns of protein polymorphisms. One of these hypotheses is the "time-divergence hypothesis" (discussed below), which makes quite different predictions concerning the factors which are apt to increase or reduce levels of genetic polymorphism[7-9].

Satisfactory testing of the niche-variation hypothesis needs several precautions. First, one must be certain that the proteins being studied 'feel' the environmental parameter(s) of interest; that is, the proteins must exist at an organism–environment interface. The temperature–protein interface in ectothermic organisms represents an especially broad interface for examining environment–protein interactions since, in these temperature-conforming species, a change in habitat temperature will lead to rapid and equivalent changes in cell temperature. Changes in habitat (cell) temperatures will lead to alterations in the velocities of enzymic reactions, changes in the higher orders of protein structure, and altered interactions between proteins and their substrates, cofactors and modulators[6]. If temperature is the environmental parameter being studied, one can therefore select any set of enzymes for electrophoretic study, knowing that all of these enzymes will be affected by variation in this environmental parameter.

Two additional precautions must be taken in designing experiments to test the niche-variation hypothesis. First, the species or populations to be compared must be phylogenetically similar, since different groups of organisms may differ in their characteristic levels of protein polymorphism[4]. Second, one must examine the same enzymes in all populations since different classes of enzymes may have characteristically different levels of polymorphism[4,10-12].

With these considerations in mind, we designed a test of the following prediction based on the niche-variation hypothesis: since temperature changes will affect all proteins in an ectotherm, species living in extremely stable thermal habitats would be expected to have less protein polymorphism (fewer isozyme forms, fewer allozyme forms, smaller percentages of loci which are polymorphic, and lower average heterozygosities) than ectotherms living in habitats where temperature varies widely with a periodicity of less than the generation time. To test this prediction we examined 13 species of marine teleost fishes which live under markedly different temperature conditions. We studied the same enzyme systems in all species and, in most cases, the electrophoretic resolution we obtained allowed us to compare analogous, if not homologous, loci among all 13 species. Since the fishes studied are native to such diverse habitats as McMurdo Sound, Antarctica, where temperature variation is but a few tenths of a ° C throughout the year, and south temperate zone estuarine and intertidal regions, where temperature variations may be of the order of 20° C seasonally, we feel that our experiments allow a powerful test to be made of the niche-variation hypothesis.

Fish specimens were obtained by collecting with quinaldine (*Mugil cephalus*, *Gibbonsia metzi*, *Bathygobius ramosus*, *Abudefduf troschelli*), by hand (grunion: *Leuresthes tenius*), with traps (*Trematomus borchgrevinki*, *T. hansoni*, *T. bernacchii*), with deep, free vehicle set-lines (*Coryphaenoides acrolepis*), or by purchase from bait shops (*Gillichthys mirabilis*) or tropical fish dealers (*Dascyllus reticulatus*, *Amphiprion clarkii*, *Halichoeres* sp.). Except for the *Trematomus* species and *C. acrolepis*, which were stored in conventional deep freezes (approximately −20° C), all specimens were killed and stored in a −76° C freezer. Samples of heart, liver and skeletal muscle, plus one or both eyes, were pooled and homogenised in two volumes of buffer (0.10 M Tris HCl, *p*H 7.0, containing 0.001 M EDTA and 0.0005 M NADP). 0.5 ml of toluene was added to each homogenate before centrifugation (12,000*g* for 30 min). The supernatants were removed and stored at −76° C.

Horizontal starch gel electrophoresis was carried out essentially as described by McKinney *et al.*[13]. The buffer systems used were (1) Poulik, *p*H 8.6 (for glutamic-oxaloacetic transaminase, acid phosphatase, phosphohexose isomerase, lactate dehydrogenase, glucose-6-phosphate dehydrogenase and esterases); (2) Tris-maleic, *p*H 7.4 (for xanthine dehydrogenase, esterases, 6-phosphogluconate dehydrogenase, phosphoglucomutase and peptidases); (3) Tris-citrate, *p*H 8.0 (for fumarase, isocitrate dehydrogenase, malate dehydrogenase, leucine amino peptidase and phosphoglucomutase); (4) Tris-citrate, *p*H 6.7 (for alcohol dehydrogenase, lactate dehydrogenase and 6-phosphogluconate dehydrogenase); (5) Tris-versene-borate, *p*H 8.0 (for α-glycerophosphate dehydrogenase, glutamic-oxaloacetic transaminase, esterases and octanol dehydrogenase); (6) lithium hydroxide, *p*H 8.6 (for leucine amino peptidase, acid phosphatase, fumarase, esterases and general proteins). Staining of enzymic activity was done essentially as described by Shaw and Prasad[14].

Whereas optimal buffer conditions varied somewhat among species, we were able to score at least 75% of the above enzymes in all species, excluding the deep sea fish, *C. acrolepis*. Only a small number of enzymes was detected in the latter species (lactate dehydrogenase, malate dehydrogenase, esterases, α-glycerophosphate dehydrogenase, phosphohexose isomerase and general protein bands), due at least in part to the removal of livers and hearts of most specimens before our acquisition of the fish. Furthermore, enzymes of species adapted to high pressure may be extremely labile[6].

Our findings (Table 1) are not consistent with the predictions

of the niche-variation hypothesis. By no criterion do the proteins of fishes from thermally variable habitats display higher levels of polymorphism relative to proteins from fishes from habitats with stable thermal regimes. Using the estimates of mean individual heterozygosity (these are less dependant on sample size than are estimates of percentage polymorphism), the six species with a thermal range of less than 5° C do not differ significantly in heterozygosity from the six species with a thermal range of 5° C or greater ($P \gg 0.10$; Wilcoxon two-sample test[15]).

What other explanations might account for the patterns of variability observed in our study? One explanation can be based on neutralist arguments. Since, in theory, the number of neutral alleles in a population at equilibrium is proportional to the effective population size[16], the different amounts of polymorphism observed among these fishes may reflect differences in population sizes. Unfortunately, we cannot test this possibility since we know of no population size estimates for any of the species studied.

A selectionist explanation for the different levels of protein polymorphism can be based on the time-divergence hypothesis[7–9] which proposes that the highest levels of polymorphism will be found in populations that have existed for very long time periods in centripetal environments, that is, environments which minimise evolutionary change because of their stability and biotic complexity. Such environments are epitomised by tropical forests, tropical reef assemblages and the deep sea. The assumptions underlying this hypothesis are, first, that heterozygosity is in general advantageous to an organism in all environments because heterosis makes a contribution, however small, to fitness. The second assumption is that directional selection over geological time erodes genetic variation and allelic diversity, whereas stabilising (centripetal) selection allows alleles to accumulate. This assumes that allelic diversity accumulates very slowly in natural populations, Evidence for the latter phenomenon in populations of lizards is discussed by M.S. *et al.* (in preparation).

The prediction based on the time-divergence hypothesis is that tropical and deep sea fishes should be the most variable. Tropical and deep sea ecosystems have probably been perturbed less in climate, latitude, species composition and diversity than other marine ecosystems[17]. Hence species living in these habitats would on the average be exposed to relatively weak directional selection and should be evolving relatively slowly. These conditions would promote the accumulation of allelic diversity.

It is interesting, therefore, that the six tropical species are significantly more heterozygous than the temperate zone and Antarctic species (excluding *C. acrolepis*); $P < 0.05$, (Wilcoxon two-sample test[15]). If the *C. acrolepis* estimate is included with the tropical species estimates, the difference is even greater ($P < 0.025$). In this regard, supporters of the niche-variation hypothesis (see for example, refs 3, 18) have predicted that niche breadth and variation ought to be inversely related to the number of sympatric species, explicitly assuming that species diversity is proportional to competition. Since the richest fish faunas are associated with tropical reefs, the tropical species would, according to this idea, be predicted to have the least variation. They do not.

Other relevant observations include the low mean heterozygosities (0.18, 0.32, 0.38) of three northern Pacific fishes of the genus *Sebastes*[19], collected in localities where the annual temperature range is about 9° C, and the high heterozygosities found in four phyla of deep sea invertebrates[20] and a tropical mollusc[21].

On the basis of our findings and those of other workers, we conclude that no strong inference about the selective control of allozyme variation can at present be made. But within the framework of selectionist arguments, we believe that the available data on polymorphism patterns can in many cases be better explained by a time-divergence model of selection than by the niche-variation hypothesis.

Table 1 Levels of genetic variation in teleost fishes from different thermal regimes

Species (Family)	Collection site (habitat)	Annual thermal range (°C)	n†	L‡	P§	$P_{0.05}$¶	$H \pm$ s.e. ‖

Nitrosation of phenols in smoked bacon

THE suggestion that nitrosamines could be formed in cured meats[1] has prompted much research into the fate of added nitrite in these foods. Because of their carcinogenicity, the major effort has been directed towards nitrosamine formation *in vitro* in cured meats and *in vivo*, but other nitrosations reported have been those of proteins[2], thiols[3] and creatine and creatinine[4]. We have recently reported our results on the nitrosation of liquid smoke emulsions in model systems[5] and we are prompted to report our studies of phenol nitrosation in smoked bacons by a recent suggestion that competitive nitrosation of phenolic residues may reduce the amount of nitrosamine formation[6].

The smoking of bacon is traditionally accomplished by hanging the meat in a smoke room filled with hardwood smoke, but recently liquid smoke preparations have been incorporated into bacon by either dipping or electrostatic spraying techniques, to produce a 'smoked' bacon. In a comparison of traditionally smoked bacon with one prepared by electrostatic spraying of a liquid smoke (supplied by Hercules Powder Co. Ltd, Erith, Kent) we have examined bacon samples from both processes in the raw and fried state and after simulated gastric digestion[2] of the fried samples; we have also examined the volatiles produced during frying. Both of these processes resulted in the deposition of phenols in the meat matrix (mainly methylphenols (cresols), 4-substituted 2-methoxyphenols (guaiacols) and 4-substituted 2, 6-dimethoxyphenols (syringols)).

The extraction method from the bacons was essentially that described by Issenberg[7] with the modifications that 5 N hydrochloric acid was used as protein precipitant and the nitroso/nitrophenols were separated from the phenols by carbonate extraction; the final concentrate (100 μl) for analysis being in ether solution. Analysis was by gas chromatography on 3% poly-(ethyleneglycol) adipate with a twin FID/thermionic nitrogen detector system. Identifications were made on the basis of the positive nitrogen detector response (a); combined gas chromatography mass spectrometry (GC-MS) (b); high resolution specific ion monitoring of GC-MS (c); and the comparison of relative (t_{phenol}) retention times with authentic compounds, and/or components present in nitrosated liquid smoke emulsion (d) (ref. 5). A control sample of green bacon was treated similarly and on analysis (highest sensitivity) no significant nitrogen containing peaks were observed.

6–Nitro–*m*–cresol ($C_7H_7NO_3$) was found in both bacons, in the fried, spray-smoked bacon and its cooking volatiles, and in raw and fried traditionally smoked bacon. The specific ion scan for *m/e* 153.04258 ($C_7H_7NO_3$) in the spray-smoked bacon volatiles gave two other peaks of t_{phenol} 1.604 and 1.721. The former, is probably the M–O· fragment ion of 6–nitroguaiacol (t_{phenol} 1.607) and the latter corresponds to an as yet unidentified peak (t_{phenol} — 1.735) also present in nitrosated liquid smoke[5].

Both bacons (spray-smoked volatiles and traditional fried) contain a peak at t_{phenol} 1.13 which is also present in nitrosated liquid smoke and has been tentatively identified as 6–nitroso–4–methylguaiacol ($C_8H_9NO_3$). A specific ion scan of the fried traditionally smoked bacon for *m/e* 167.0582 ($C_8H_9NO_3$) produced an intense peak at t_{phenol} 1.137 which suggests that this is identical to the above nitrosophenol from nitrosated liquid smoke. Three other peaks of *m/e* 167.0582 were identified in addition to the above, from this scan, of t_{phenol} 1.310, 1.712 and 1.814 respectively. Again by comparison with nitrosated liquid smoke the first of these (1.310) is probably the M–C_2H_4· fragment ion of 6-nitroso-4-propylguaiacol tentatively identified in the former, the second is probably the M–O· ion from 6-nitro-4-methyl-guaiacol and the last is unknown.

Efforts to improve the quantitative aspects of our extraction and analysis are in progress but not yet complete; estimates of the concentration of the individual nitroso/nitrophenols are at least one order of magnitude greater than the volatile N-nitroso compounds which have been found in bacon.

The identifications made to date are summarised in Table 1; including the compounds listed, a total of 19 significant nitrogen containing compounds were found in extracts from spray-smoked bacon and 12 from traditionally smoked bacon. Several of these have the same relative retention time as compounds identified in nitrosated liquid smokes as nitro- and nitroso-derivatives of cresols, guaiacols and 4-alkylguaiacols. These observations indicate that nitrite interaction with a wide variety of smoke phenols occurs in bacon during production, frying and gastric 'digestion'.

Some comments about the possible biological effects of compounds of these types have been made[6] but these are based mainly on their chemical properties and a proper assessment must await further investigation as must the possible role of phenol nitrosation as a reaction which competes with N-nitrosation for the limited quantity of nitrite available in cured meat. The evidence obtained so far indicates that the formation of nitroso- and nitro-phenols is sufficiently important for it to be

Inhibition of inter-microbial predation by chlorinated hydrocarbons

TIDAL or estuarine regions have traditionally served as sinks for municipal sewage. Some microbial predators in the sea feed on the enteric bacteria contained in such sewage[1]. Recently, the concentration of chlorinated hydrocarbons in the sea, especially in estuarine regions, has increased although it remains considerably below the concentration which directly affects the viability of predators or intestional pathogens. But, estuarine chlorinated hydrocarbon concentrations are within a factor of 20 of those which we have observed to inhibit the chemotactic response of marine bacteria[2]. Because bacterial predators are chemotactic specifically to exudates of their prey[3], inhibition of chemotaxis by chlorinated hydrocarbons may directly affect estuarine self-purification rates. We report here the impact of two chlorinated hydrocarbons, at concentrations observed to inhibit chemotaxis[4], on enteric bacteria predation.

We examined the rate of kill of *Escherichia coli* by marine predators in the presence of 2,4-dichlorophenoxyacetate (2,4–D) and *o,o*-dichlorobiphenyl. The predators were isolated from seawater by repeated subculture in artificial seawater[5] using *E. coli* as the sole carbon source. The resulting predators displayed positive chemotaxis to *E. coli*. The level of kill of *E. coli* in 48 h by the predators in 50 ml portions of artificial seawater was determined by serial dilution and plating in triplicate on EMB agar (Difco) containing lactose. The die-off experiments were run in duplicate with two flasks placed on a rotary shaker (approximately 60 r.p.m.) and two on the laboratory bench at room temperature. Initial predator populations were estimated by five tube most-probable-number counts using the clearing of a tube containing 10 ml of a 10^8 ml^{-1} solution of *E. coli* in artificial seawater as a positive result.

We made several attempts to isolate a single predator species from the mixed predator culture. Methods used included: colony isolation on a broad spectrum of enriched artificial seawater-agar or gelatin solid media; isolation by serial dilution; or isolation by filtration through a series of Millipore filters. In every case a mixed culture resulted when the isolates were reinoculated into artificial seawater with *E. coli* as the sole carbon source. The predator culture consisted of at least two distinct *Spirillum* species as well as one motile pseudomonad. The dominant predator species (90% by visual count in liquid culture) was a *Spirillum* (approximately 1 μm diameter; two spiral turns). The presence of this predator mixture of visable organisms was necessary for *E. coli* lysis. The predator culture filtrate, when passed through a 0.45 μm Millipore filter, did not contain these organisms and also did not produce lysis of *E. coli*. There was no evidence of Bdellovibrios or bacteriophages in the filtrate.

The mechanism of *E. coli* lysis by the dominant *Spirillum* does not seem to be direct contact. The lysis mechanism seems to be based on the maintenance of a critical concentration of lytic enzymes although we were unable to obtain culture extracts which would lyse *E. coli* cultures in the absence of living predator cells. The predacious *Spirilla* utilised materials available in cell walls in that they could be subcultured in artificial seawater containing washed *E. coli* cell walls as the sole carbon source.

Inhibition of kill of *E. coli* by marine predators in the presence of chlorinated hydrocarbons is shown in Table 1. A decrease in the rate of kill was generally observed in the shaken flasks containing the chlorinated hydrocarbons and the percentage kill was no longer directly related to the initial population of the predators. In the standing flasks, the percentage kill generally decreased in the presence of the lower concentration of chlorinated hydrocarbons. In the presence of higher concentrations of the chlorinated hydrocarbons, the percentage kill of *E. coli*

Table 1 Percentage kill of *E. coli* in 48 h by motile marine predators in the presence of chlorinated hydrocarbons

Initial predator population no. per ml.	No chlorinated hydrocarbons	2, 4-D 10^{-4} M	2, 4-D 7×10^{-3} M	*o, o*-Dichlorobiphenyl 10^{-5} M	*o, o*-Dichlorobiphenyl 10^{-3} M

10^5	30	10	29	13	39
10^7	72	26	41	41	47
Fully mixed					
10	20	23	25	18	27
10^3	54	29	41	31	44
10^5	61	32	43	30	43
10^7	71	77	44	55	51

The initial *E. coli* population was 10^7 ml^{-1}. The data are corrected for kill observed in the absence of the predators.

in the standing flasks was generally increased in those flasks in which the initial predator population was less than 10^7 ml^{-1}. The viability of the predators and of *E. coli* was not affected by either the low or the high concentrations of the chlorinated hydrocarbons. This was determined by predator cell counts in control flasks lacking *E. coli* and by *E. coli* counts in control flasks lacking the predators. The activity of the predators also did not seem to be affected by the chlorinated hydrocarbons as shown by a glucostat determination[6] in which the rate of consumption of glucose did not decrease even in the presence of the higher concentration of hydrocarbons.

The lower concentrations of chlorinated hydrocarbons, which significantly decreased the percentage kill of *E. coli* by marine predators in shaken culture, are approximately a factor of 20 greater than those observed in natural ecosystems. Waste effluents, which contain intestinal pathogens of which *E. coli* is an indicator, may contain chlorinated hydrocarbons at concentrations ten to a hundred times greater than seawater residual levels. Such chlorinated hydrocarbons, acting either singly or in combination, may decrease the level of predator—prey interactions responsible for self-purification in natural ecosystems in the vicinity of outfalls.

The lower chlorinated hydrocarbon concentrations, which decreased the percentage kill of *E. coli*, are similar to those we previously reported to inhibit chemotaxis in motile marine bacteria[4]. The higher hydrocarbon concentrations, which increased kill rates in the standing culture flasks for lower predator populations, are those which we observed to increase chemotaxis. This correlation suggests that the observed changes in *E. coli* kill rates are the result of inhibition or excitation of the chemotactic response in the marine predators of *E. coli*.

Formation of methylmercury in a terrestrial environment

WOOD *et al.*[1] demonstrated that the mercury from inorganic chemicals can be methylated by aquatic organisms and also, enzymatically, by extracts of methanogenic bacteria. Since the organic forms of mercury are reported to be more biologically available, these methylation processes in aquatic or sedimentary environments, together with the tendency of methylated mercury to accumulate in biota, are a major reason for bioconcentration of mercury in fish and other organisms found in lakes, streams and bodies of seawater that are contaminated with mercury. As methanogenic bacteria also occur in terrestrial environments, we have investigated possible organomercury compound formation in soils contaminated with an inorganic mercury compound.

In a preliminary laboratory study, several 100 g soil samples were spiked with ^{203}Hg as mercuric nitrate, and incubated. Extraction of these samples with hydrochloric acid, followed by benzene extraction of the aqueous phase resulted in increased activity in the benzene fraction compared with reagent blanks. This indicated some conversion of the mercuric nitrate to a chemical form more soluble in benzene, presumably some organic form.

These results prompted us to spike small agricultural plots, at the Environmental Protection Agency's experimental farm at the Nevada Test Site, with radioactively labelled mercuric nitrate. Approximately 1 μCi ^{203}Hg m^{-2} (specific activity 2–20m Ci g^{-1} according to the supplier's specification) was applied in the form of an aqueous solution to the bare sandy loam soil (soil *p*H about 8.5). Plots were watered daily, and starting at the time of application, soil samples were collected periodically and extracted with 2.2 N HCl; organic mercury compounds contained in the filtered aqueous solutions were extracted into benzene. The benzene extracts were concentrated by column distillation; the concentrate was washed with 2.2 N HCl, and the mercury compounds extracted into 1% cysteine acetate solution as described by G. Westöö[2]. The mercury compounds in the cysteine acetate solution were then extracted into a small volume of a benzene solution of dithizone (0.4% w/v). Excess dithizone was removed by treatment with H_2SO_4 and NH_4OH (ref. 3); no attempt was made to achieve a quantitative recovery.

Thin-layer chromatography (TLC) of a portion of the dithizonate solution was performed on Gelman silica gel instant TLC sheets in a Gelman chromatography chamber using a carbon tetrachloride:benzene mixture (75:5 v/v) as the mobile phase. Isolated spots consisting of a mixture of stable mercuric dithizonate, phenylmercuric dithizonate and methylmercuric dithizonate were applied on each side and in the centre of the same TLC sheet and developed together with the radioactive dithizonate extract, to serve as indicators. In control experiments carried out under identical conditions the R_F values for mercuric dithizonate, phenylmercuric dithizonate and methylmercuric dithizonate were determined as 0.19, 0.52 and 0.63, respectively.

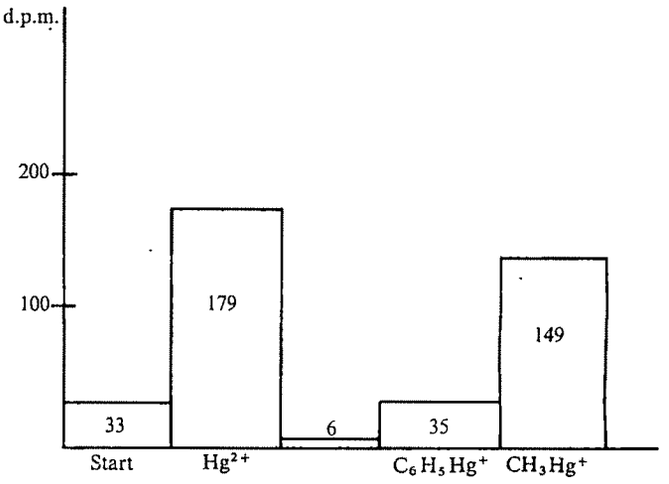

Fig. 1 Distribution of ^{203}Hg on thin-layer chromatography sheet.

The developed, air-dried TLC sheets were cut immediately into horizontal segments using the coloured indicator spots of the above-mentioned stable mercury compounds as reference points, and the individual segments were analysed for radioactivity content by gamma-counting. Figure 1 shows that more than one-third of the total activity of the dithizonates was concentrated in the range of the methylmercuric dithizonate.

It is not known whether the activity found in the range of the phenylmercuric dithizonate was due to phenylmercuric dithizonate originating from mercuration of benzene during extraction, tailing of the alkylmercuric dithizonate, or to some as yet unidentified mercury compound with an R_F similar to that of phenylmercuric dithizonate. A control experiment using a heat-sterilised soil sample which was spiked with $^{203}Hg(NO_3)_2$ solution and analysed as described above showed no activity in the methlymercuric dithizonate range but some activity (about 2%) in the phenylmercuric dithizonate range of the TLC sheet. A portion (2–10%) of the total ^{203}Hg contained in the soil samples was not soluble in 2.2 N HCl after repeated extractions. It could, however, be extracted readily into cold 2.2 N HNO_3, indicating some conversion to elemental mercury. This conversion is not surprising as certain bacteria can convert virtually all mercury compounds into elemental mercury[4–6].

These results show that mercuric salts can, under agricultural conditions, be transformed into methylmercury. We could not differentiate between methyl and dimethylmercury because during extraction, dimethylmercury would have been converted to the monomethyl compound, according to $(CH_3)_2Hg + HCl \rightarrow CH_4 + CH_3HgCl$. The conversion in a terrestrial environment of inorganic mercury compounds to methylmercury implies that recycling of mercury from soil to air and back to soil or water could occur faster than presently assumed on the basis of the volatility of metallic mercury and inorganic mercury compounds alone. Due to the formation of methylmercury compounds and their high volatility,

mercury compounds deposited in soil are more readily available to humans and animals than previously anticipated, the consequent health hazard being magnified by the higher toxicity of methylmercury.

New finding of the ancient primitive mollusc *Neopilina* in the Atlantic part of the Antarctic

The mollusc *Neopilina* (Monoplacophora) was first found 20 yr ago in the Peru-Chile Trench of the Pacific Ocean[1]. *Neopilina* has since been found in other places[2–4] including various areas of the Pacific, the northern Indian Ocean and the Atlantic part of the Antarctic. So far, no *Neopilina* has been encountered in the Atlantic Ocean proper, though it probably occurs there.

The first *Neopilina* found in Antarctic waters was an immature specimen of *N.(Neopilina)*. It was 2.3 mm long and 2.0 mm wide, with five pairs of gills[3]. It was taken from depths of 1,647 m to 2,044 m at the eastern slope of Burdwood Bank (54°43′ S, 55°30′ W).

Neopilina was found for the second time in the Antarctic during the eleventh biological cruise of the vessel Akademik Kurchatov (1971–1972). The bottom fauna was sampled by this expedition in the northern parts of the South Sandwich and South Orkney Trenches. One of the sections runs across the South Antilles basin (Scotia Sea) and the eastern slope of the Falkland shallow. Two deep sea trawlings were made in the small trench situated in the north-western part of the Scotia Sea. One living adult specimen of *Neopilina* was found on December 14, 1971, 56°29′ S, 50°51′ W. The depth was 4,664–5,630 m, and the bottom consisted of mud with sand and pebbles.

This specimen of *Neopilina (Neopilina)* was 19 mm long, 15 mm wide and 8.5 mm high. The mollusc was broken during trawling and the edges of its shell overlapped slightly behind, so its width is in fact a little greater (by 1–1.5 mm). The apex is shifted (as usually) to the front margin and hangs over it. The valve surface contains very fine and delicate but pronounced concentric folds. The radial striation is the finest and becomes visible only under magnification; five pairs of gills are well developed; the labial palpi have short marginal bordering.

It is quite possible that the small *Neopilina (Neopilina)* specimen found previously on Burdwood Bank[3] was a young form of the *Neopilina* we describe. The taxonomic position of the small mollusc is being investigated.

The bottom fauna found with our specimen was very rich and diverse, containing more than 20 groups of bottom invertebrates. There were several hundred holothurians (including *Elpidia*—the leading form of bottom fauna here), numerous Pourtalesiidae (irregular deep sea urchins) and Ophiuroidea, rich population of Polychaeta (Aphroditidae, Flabelligeridae and others), various Spongia, Actinia, Pogonophora, Amphipoda and Isopoda. Molluscs (apart from *Neopilina*) were represented by Gastropoda, Prosobranchia and Opisthobranchia and Bivalvia (*Cyclopecten* and *Neilo*).

It therefore seems that the food and conditions are quite adequate for recent *Neopilina* and other detritus-feeding bottom invertebrates in the South Atlantic eutrophic regions. The hard substratum to which *Neopilina* adheres (stones, manganese nodules or pebbles) is dispersed in good quantity in the Antarctic region by the action of floating ice. The mucus bacterial film or organic detritus in various forms usually existing on the surface of such hard substratum is used by *Neopilina* as food. They can easily scrape it off with the long thin denticles of brush-like parts of their radula. Therefore the subantarctic regions of the Atlantic Ocean are very favourable for them, especially the areas influenced by the temperate warm waters of the Falkland current washing the slopes of Falkland shallow water zone.

The existence of well-dispersed hard substratum, usually covered with bacterial film can explain the existence of *Neopilina* forms even in parts of the ocean very poor in food and bottom fauna; for example *Neopilina oligotropha* in the North Pacific[4].

Effects of stable chlorine-containing organics on aquatic environments

During 1962, approximately 60,000 tons of chlorine were added to the effluents of sewage treatment plants in the United States[1] and subsequently released to surface waters. By 1970, it was estimated that 100,000 tons of chlorine were added annually, and the quantity will continue to increase as municipalities are required[2] to provide at least secondary treatment for sewage by July 1, 1977 (ref. 3). Principal reactions of chlorine in natural waters, besides hydrolysis, are with ammonia and organic amines[4,5]. Reactive chlorine residuals, for example, hypochlorites, inorganic and organic chloramines, are characterised by reactive chlorine which would decompose or be consumed in various chemical reactions[5]. Jolley[3] has identified seventeen stable chlorine-containing organic compounds at low $\mu g\ l^{-1}$ concentrations in chlorine-treated sewage effluent. The persistent nature of these compounds, which are characterised by chemically stable or inert C–Cl bonds, suggests potential for their accumulation in receiving surface waters[6,7].

Research on the toxicity of reactive chlorine residuals to aquatic life has been extensive[8]. The identification of stable chlorine-containing organics has revealed a group of reaction products which arise from chlorination. Not only are the toxicities of these compounds unknown, but analytical methods used for measuring concentrations of reactive chlorine residuals fail to account for their presence. The identification of stable chlorine-containing organics indicates the need for further research in order to evaluate the total toxicity of all reaction products formed from chlorine released into natural waters.

We report here data on the toxic effects of two species of stable chlorine-containing organic compounds, 4-chlororesorcinol and 5-chlorouracil, on the hatchability of carp (*Cyprinus carpio*) eggs.

Gravid carp were collected and spawned artificially in the laboratory as described before[9]. Tests were run on eggs fertilised and left undisturbed for 30 min before addition of test solutions (water-hardened eggs) and on eggs fertilised immediately in the test solutions (non-water-hardened eggs). The latter were subjected to the toxicant during the hardening procedure. After 30 min the aqueous solutions were decanted and fresh solutions of the appropriate chemical concentrations were added. For each chemical, tests were run at two temperatures (21° and 26°C) with nine concentrations (ranging from 0.001 to 10 mg l^{-1}) plus controls. Two replicates (200–400 eggs each) were performed for each concentration. After the water-hardening period the containers were kept in controlled environment rooms at 21°C or 26°C until the eggs hatched (about 3 d at 26°C and 7 d at 21°C). Twice daily during this period solutions were changed and dead eggs and those infected with fungus were recorded and removed.

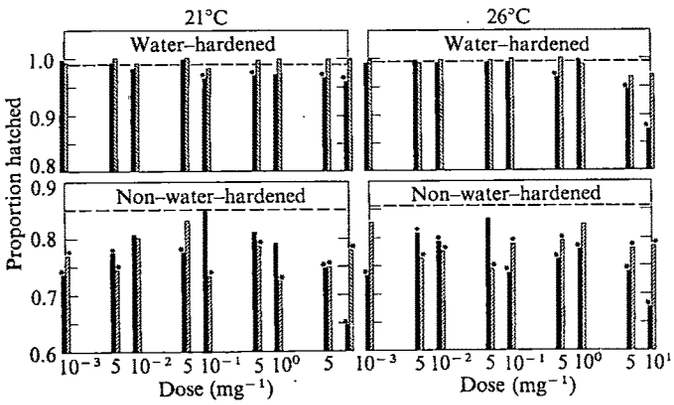

Fig. 1 Response (hatching success) of carp eggs. *Response significantly below ($\alpha<0.05$) controls. Black columns, 4-chlororesorcinol; hatched columns, 5-chlorouracil; ---, control response.

All concentrations were based on serial dilutions prepared in the laboratory rather than *in vivo* measurements. Although the latter is desirable, sensitive analytical procedures are not yet ready for use. These chemicals are relatively stable and the total test period for a run was always less than a week; therefore, qualitative and (or) quantitative changes in the test medium would not be expected.

Results of the tests were scored on the basis of the percentage of the eggs initially placed in a container that hatched. The responses from the replicates at each dose were tested and not found to be significantly different $\alpha=0.05$, assuming a normal approximation to the binomial distribution); therefore the replicates were pooled to give the percentage responses shown in Fig. 1. The mean of the two replicates at each concentration was then compared with the mean of the controls (Fisher's exact test)[10] to determine if a significant decrease in hatchability occurred.

Comparison of the relative toxicity of the two chemicals on non-water-hardened eggs at the two temperatures (Fig. 1) indicates similar toxicity with concentrations of 0.001 mg l^{-1} significantly lowering hatchability in all but the 26°C 5-chlorouracil test medium. This level (0.001 mg l^{-1}) is below the estimated concentrations of stable chlorine-containing organics present in effluents of waste water treatment plants[3]. There seems to be an area at the midrange of concentrations (about 0.05 mg l^{-1}) where no significant effect on hatchability was seen. Whether this resulted from some physical or physiological relationship between toxicant levels and eggs, or possibly from some fungicidal activity of the chemical, is not known and deserves further study. This phenomenon does not detract from the results, however, since the 0.001 mg l^{-1} concentrations exhibited a significant reduction of hatchability. This level (0.001 mg l^{-1}) cannot be taken as the lower incipient lethal level since lower concentrations were not tested.

Eggs that were water-hardened before exposure to the toxicants were more resistant to the toxicants than were non-water-hardened eggs (Fig. 1). Hatching success of water-hardened eggs was similar to or greater than the controls for most of the dose range of toxicants tested, whereas in the non-water-hardened eggs hatching success was always lower than controls (with the exception of 0.1 mg l^{-1} of 4-chlororesorcinol at 21° C). There were no toxic effects except at concentrations $\geqslant$ 0.1 mg l^{-1} of 4-chlororesorcinol. No toxic effects of 5-chlorouracil were seen in water-hardened eggs at 21°C, whereas hatchability was significantly lowered at concentrations $\geqslant$ 5 mg l^{-1} at 26°C.

The data presented here show that both 5-chlorouracil and 4-chlororesorcinol significantly decreased the hatchability of non-water-hardened carp eggs when tested in concentrations as low as 0.001 mg l^{-1}. Results of our research are important not only as the first source of data on toxicity of specific stable chlorine-containing organics, but as a signal that such compounds (which have now been reported to be formed in reactions of chlorine with organic matter in natural waters)[3] need to be considered in future tests of chlorine toxicity.

This work was sponsored by the US Atomic Energy Commission under contract with Union Carbide Corporation.

book reviews

New philosophy at Leiden

Physics at 17th and 18th Century Leiden: Philosophy and the New Science in the University. By Edward G. Ruestow. Pp. 174. (International Archives of the History of Ideas. Series Minor 11.) (Nijhoff: The Hague, 1973.) 24.50 guilders.

WITH the growing interest in the external relations of science during recent years, increasing attention has been devoted to a study of the development of science within various institutional contexts. While the major thrust of this research has focused upon social factors, there has also been some attention given to the development of ideas within the institutions themselves and, particularly in the wake of Kuhn's seminal book, various attempts to delineate the institutional implementation of new scientific ideas to replace the old ones. E. G. Ruestow's study treats the development of one science at a single institution during a two-century period. As such it is a useful case study of the change in scientific orientation within firmly fixed temporal and spatial limits.

The University of Leiden was founded in 1575 as the first Dutch university. With an amazing rapidity it achieved a position of eminence which it has retained through most of its life. Though it had a small beginning with only ten professors, it gradually expanded, and what it lacked in size it made up in quality. Already in the seventeenth century it had a notable library and numerous distinguished professors, not only in scientific subjects, but perhaps even more preeminently in humanistic disciplines. Ruestow selects one strand of its development during the first two centuries of the university's life and attempts to trace the fortunes of physics teaching. The bulk of his book centres on the period from Burgersdijk to Musschenbroek (about 1610-1760).

Franco Burgersdijk was the first philosophy professor at Leiden to gain international distinction. As Dibon's careful researches have shown, his textbooks went through many printings not only in Holland, but in England as well, Burgersdijk's books on logic and natural philosophy being part of the staple diet of students at seventeenth-century Oxford and Cambridge. The chapter on him is a useful summary, though it does not really penetrate as deeply into the sources and characteristic organisation of Burgersdijk's writings as one might wish. After Burgersdijk's passing, his Aristotelian orientation gave way to the attempts at a Peripatetic-Cartesian synthesis in natural philosophy, particularly on the part of his successors Heereboord and De Raey. After a period of Aristotelian counterattack, experimental philosophy begins at Leiden, the first request being made in 1694 to institute an experimental approach to physics. Naturally enough, the early work was on the beaten path of vacuum experiments and other topics which had become subject to this new approach during the previous half century. Early in the eighteenth century, however, the Newtonian revolution reached Leiden and principally through the efforts of 'sGravesande and Musschenbroek became firmly established. Thus Leiden's university became one of the first to espouse the "new philosophy".

Ruestow's story is an interesting one and it bears comparison with the situation in other universities. Though he does not bring to light any new sources, he makes good use of the available ones. Not only has he read extensively in the writings of the professors themselves, but he makes ample use of the documentary history of the university, especially of the magisterial compilation of sources published by Molhuysen more than a half century ago. Moreover, he brings to general attention and summarises the results of various specialised Dutch studies touching on the topic. Perhaps one could have wanted a more detailed bibliography not only of the publications of the professors, but also the hidden articles on their lives. Too often the *Nieuw Nederlandsch Biografisch Woordenboek* is uniquely relied on. Moreover, it seems to this reader that a slight distortion has been introduced by taking the study of physics too much in isolation from other subjects being taught at Leiden (such as botany, medicine, and chemistry, as well as theology). More could also be learned about outside influences, especially from Italy.

In conclusion, here is a good, solid study of a limited area of investigation. It is generally a reliable guide to the subject and, if not as exciting as it might have been, it should serve to recall to English readers the importance of Leiden as a scientific centre. What is more, it is written in a sober and value-free way, which is important at a time when many historical studies are infected with attempts to show that one or another present-day philosophy of science is the uniquely true one.

C. B. SCHMITT

Tropical diseases

Trypanosomiasis and Leishmaniasis with Special Reference to Chagas' Disease. Pp. xii+353. (Ciba Foundation Symposium 20 (new series) held jointly with the Venezuelan Academy of Sciences and "La Trinidad" Medical Center, Caracas.) (Elsevier/Excerpta Medica/North Holland: Amsterdam, London and New York, 1974.) Dfl.46; $18.40.

AMONG the most important diseases of man in tropical and subtropical countries are Chagas' disease in America, sleeping sickness in Africa and leishmaniasis, in its various forms, in both the Old and New Worlds. These diseases are very different from one another but they have one thing in common; they are all caused by flagellates belonging to the order Kinetoplastida. Clinicians and research workers all over the world are studying isolated aspects of the biology of these flagellates and this symposium represents a commendable attempt to bring some of them together and to pool their findings and thoughts.

The fourteen papers in this collection are all by recognised authorities. Three are devoted to Chagas' disease, three to sleeping sickness and two to leishmaniasis. Six cover all three diseases and the discussions which follow each paper also contribute to this common theme.

The taxonomic framework of the Kinetoplastida is summarised by W. H. R. Lumsden and there are chapters on ultrastructure (K. Vickerman), nutrition and biosynthesis (W. Trager), intermediary metabolism (I. B. R. Bowman), chemotherapy (B. A. Newton) and drug resistance (W. Peters). Sleeping sickness is considered from the points of view of epidemiology (J. R. Baker), pathogenesis (L. G. Goodwin) and immunity and antigenic variation (P. de Raadt). The coverage of leishmaniasis is restricted to its epidemiology (R. S. Bray) and the clinical immunopathological aspects of American cutaneous leishmaniasis (J. E. Convit and M. E. Pinardi). The epidemiology of Chagas' disease is described by R.

Zeledón and there are two chapters on its pathology, one by A. Anselmi and F. Moleiro and the other by F. Köberle.

Most of the chapters are well written and straightforward accounts which reveal both the extent of and gaps in present knowledge. The two chapters on the pathology of Chagas' disease represent alternative views. The section on antigenic variation in trypanosomiasis is probably the most speculative in the symposium and the one least likely to survive the passage of time.

What emerges is an excellent statement of the present situation with regard to these diseases. Much of it is a textbook and will be used as such. It is also a source book for those seeking new (or first) fields to conquer and a reference book for those involved in teaching, research and clinical medicine. Two points, however, may confuse uninitiated readers. *Leishmania aethiopica* is mentioned on pages 102 and 250 but not in the check list in the first chapter. Although described after the meeting, this parasite should have been added in proof. *Schizotrypanum* is given subgeneric status in chapter 1 but occasionally reverts to generic status during subsequent discussions.

One fact comes over above all others from this symposium, the deficiency in understanding of Chagas' disease. Here is a disease that affects 35 million people and in parts of Brazil is responsible for one third of all adult deaths. Yet we do not know how many forms of the causative agent, *Trypanosoma cruzi*, exist nor do we have a single drug that is effective once the parasite reaches its host cell.

F. E. G. Cox

History of salt water

The Development of the Chlorinity/Salinity Concept in Oceanography. By William J. Wallace. Pp. xii+227. Elsevier Oceanography Series, Vol. 7. (Elsevier: Amsterdam, London and New York, 1974.) Dfl.46; $17.70.

THE author starts with a careful summary of Greek and Arabic writings about salt, mineral waters and seawater. Errors that appear in Riley and Skirrow are repeated in a paragraph quoting a letter from Synesius to Hypatia describing a hydrometer in about 410 AD. Boyle's *Observations and Experiments on the Saltness of the Sea* is treated as a landmark, and also Halley's study of evaporation, particularly his work on the Mediterranean Sea, and on condensation at higher levels as he saw it in St Helena. Lavoisier is shown as mainly interested in medicinal waters though adding considerably to what was known about the sea. Bergman's analyses began to hint that the main constituents of sea salt are always present in the same proportions.

The careful work of John Murray, published in 1818, brought reproducibility to sea water analysis. Marcet formulated the principle of constancy of composition in 1819, and Forchhammer, and Dittmar who analysed samples collected during HMS Challenger's circumnavigation, confirmed it. Measurement of total solids by evaporation does not give consistent results, and experience showed that for common use it is better to rely on estimated values based on measurements of chlorine content. Sorensen in Sweden and Knudsen in Denmark put the procedure on a systematic basis by careful work in 1899–1902. They refined the methods, initiated a distribution of Standard Sea Water for everyone to use, and published tables relating chlorinity to salinity and density, so that before long all results could be combined into maps and sections sufficiently detailed and consistent to trace water movements, and to work out pressure patterns. There was no reason other than some self satisfaction or sense of completeness why salinities should have been plotted rather than the chlorinities on which they were based.

The final part of the book deals with changes inspired by more recent improvements. The measurement of electrical conductivity is now an easier and more accurate routine than chlorine determination, and salinity has been newly defined in terms of conductivity. The author reviews the problems that remain. The Standard Sea Water is being used as a reference for conductivity instead of chlorinity, though each main batch is checked. The difficulties of measuring absolute conductivity and density are still not surmounted. So long as careful checks are maintained the standards are adequate, but the author thinks we may lose if unquestioning acceptance of constant relationships between chlorinity, electrical conductivity, density, and other physical properties and chemical constituents, discourages critical study of small exceptions to the rule. Such exceptions may, as refined methods are more widely used, provide new lines of investigation into the origin and history of water mixtures.

The author has done a great service to the history of marine chemistry. Judging from his text and very extensive bibliography his work seems to have been completed in about 1970, or he would have included something about Kremling's (1971) new method of measuring density, and recent reports of the Joint Panel on Oceanographic Tables and Standards, set up by Unesco and the international marine science organisations to take care of the new problems.

G. E. R. Deacon

Abandon dualism

Quantum Mechanics in a New Key. By Alfred Landé. Pp. x+130. (Exposition: New York, 1973) $6.50.

THE author states in the introduction his intention to derive quantum mechanics from three non-quantal postulates. These are: symmetry (the probability $P_{\beta\alpha}$ connecting two states α and β is two-way symmetric, so that $P_{\alpha\beta}=P_{\beta\alpha}$); correspondence (the probabilities connecting various pairs of states are to be interdependent by way of a general theorem which is to yield the ordinary probability addition law $P_{\alpha\gamma} = \Sigma_\beta P_{\alpha\beta}P_{\beta\gamma}$ in the average; and covariance (there are no preferred zero points for energy and momentum, nor for time and space coordinates). In this way the author hopes to demonstrate that quantum mechanics is a logically consistent theory of probability and symmetry, and that the wave–particle dualism which emerged in the early history of the subject may now be abandoned as an unnecessary mystification.

In chapter 1 he discusses several critical experiments, and uses Duane's theory of diffraction, originally put forward to explain the diffraction of photons, to show how wavelike effects such as interference may be explained without assuming the existence of matter waves. In chapters 2 and 3 the first and second postulates are introduced and their consequences are considered; these are further developed in chapter 4. The third postulate and its consequences are discussed in chapter 5. Statistical thermodynamics is briefly considered in chapter 6; the author returns to his main theme of observation and interpretation in chapter 7.

The aims of the book are admirable, and most physicists would probably accept the philosophy which it expounds. The lack of mathematical rigour would not, in itself, be a disadvantage in a book of this kind, but unfortunately the author's conclusions do not always seem to follow from his postulates. For example, the statements $P_{\alpha\beta} = |\Psi_{\alpha\beta}|^2$ where $\Psi_{\alpha\beta}=\Psi^*_{\beta\alpha}$ and $\Psi_{\alpha\gamma}=\Sigma_\beta\Psi_{\alpha\beta}\Psi_{\beta\gamma}$ do not obviously follow from the first two postulates. Rather these should themselves be regarded as the basic postulates, from which the first two postulates are then easily deduced. Symmetry and correspondence provide a guide to the choice of postulates, rather than themselves being postulates. The deduction of the result $\Psi_{pq} = C\exp(2i\pi pq/h)$ in chapter 5 from the postulate of covariance, and the derivation of the Schrodinger wave equation from this result are elegant, but I think that the reader would have been helped by a more detailed explanation of the mathematical reasoning behind the steps of the arguments.

J. E. G. Farina

obituary

B. E. Bykhovskii

ACADEMICIAN BORIS EVSEEVICH BYKHOVSKII, a leading Soviet parasitologist, and Director of the Institute of Zoology of the Academy of Sciences of the USSR, died on January 26, 1974.

Bykhovskii was born in 1908, in St Petersburg, and was educated at Leningrad University, graduating from the Biology Department in 1930. His first scientific post was as a laboratory assistant at the Institute of the Fishery Industry; by 1939, when he left the Institute, he had risen to the rank of senior scientist. In 1939, he moved to the Institute of Zoology of the Academy of Sciences of the USSR, which was from then onwards the centre of his scientific activity. From 1940–44 he worked in Tadjikstan as Deputy Chairman of the Tadzhik branch of the Academy, playing a great part in the transformation of this branch into the new Academy of Sciences of the Tadzhik SSR. From 1942–59 he was Head of the Laboratory of Helminthology of the Institute of Zoology of the Academy of Sciences of the USSR, and, simultaneously and until 1962, Deputy Director of the Institute of Zoology. In 1962 he became director of the Institute, a post which he was to hold for the rest of his life. In 1960 he was elected a Corresponding Member and in 1964 a Full Member of the Academy of Sciences of the USSR.

Bykhovskii's main field of research was the helminths of fish. His publications, however, deal with a considerable range of associated problems of general parasitology, ecology and evolution. He organised over twenty-five scientific research expeditions and was founder and Editor in Chief of the journal *Parasitologiya*.

His best-known papers include *Contributions to Knowledge about Monogeneic Trematodes with a Primitive Fastening Armature* (1955); *Information on Monogeneic Trematodes in the Fishes in Tadjikstan* (1960); *The Monogeneic Trematodes of* Silarus glanis (1966); and *Results and Further Prospects of the Work of Soviet Parasitologists in the Study of Parasites of Fish in the Seas of the USSR*.

In September 1965, at the joint session of the Presidium of the Academy of Sciences of the USSR and other scientific institutions, Bykhovskii was among those who strongly criticised Lysenkoism and its adverse effect on Soviet science. His support for the anti-Lysenkoists was of particular importance, as, unlike several other critics, Bykhovskii was a keen Party member with an active interest in politics, and from time to time held official positions in the Leningrad City and Regional Party organisations.

For his services to science and to the fishing industry, Bykhovskii was awarded a number of Soviet decorations including the Order of Lenin and the Order of the Red Banner of Labour.

P. K. Anokhin

ACADEMICIAN PETR. KUZ'MICH ANOKHIN, the eminent Soviet physiologist and brain specialist, died on March 6, 1974.

Anokhin was born on January 27, 1898, in Tsaritsyn (later Stalingrad and now Volgodrad). The son of a worker, he began his studies at the local agricultural and technical college, but, in 1917, these studies were interrupted by the revolution. Anokhin, whose sympathies were with the revolutionaries, took an active part in the defence of Trasitsyn and in the establishment of Soviet rule in the Don area, becoming, towards the end of the civil war, Commissar of Publications in Novocherkassk, and editor of the newspaper *Krasnyi Don*. In this latter capacity, while browsing for subject matter for popularised science articles, he happened upon a publication of the Leningrad Brain Institute, and became fascinated by the work of Bekhterev and Pavlov on conditioned reflexes.

When the civil war ended, Anokhin was able, through the intervention of A. V. Lunacharskii, People's Commissar for Culture, to transfer his studies to the Leningrad Institute of Medical Science where he graduated in 1926. After graduation, he proceeded to Pavlov's own laboratory, working and studying under Pavlov and Bekhterev until 1930, when he was appointed Professor of the Department of Physiological Medicine at the University of Gor'kii, a post which he held until 1934. Later positions included Head of the Department of General Physiology of the Higher Nervous System at the All-Union Institute of Experimental Medicine (1934–46), Director of the Institute of Physiology of the Academy of Medical Sciences of the USSR (1946–49), Head of the Departments of Physiology and Pathology of the Higher Nervous System at the Central Post-Graduate Medical Institute (1936–49 and 1953–55), and Head of the Department of Normal Physiology of the I. M. Sechenov Moscow Medical Institute. During the Second World War he served as neurosurgeon and assistant to the renowned surgeon Nikolai N. Burdenko.

Throughout his working life, Anokhin maintained the interest in conditioned reflexes and the action of the brain, which had first attracted him to neurophysiology. He extended and amended Pavlov's fundamental ideas in the light of later research and put forward a highly complex picture of brain reaction to stimuli, involving a number of areas of the brain, including subcortical areas. One of his postulates was that some 'intention' to perform an action must emerge between stimulus and reaction. Other fields in which he did notable work included the physiological theory of the neural cicatrix, the theory of pathogenesis of amputation pains and central paralysis, and medical cybernetics.

His numerous publications include *Problem of the Central and Peripheral Nervous systems in the Physiology of Nervous Activity* (1935); *Neuroplasty for Battle Injuries of the Peripheral Nervous System* (1944); *Systemogenesis as a General Rule of the Evolutionary Process* (1948); *General Principles of the Compensation of Functional Perturbances and their Physiological Basis* (1954), *Internal Inhibition as a Problem of Physiology* (1958); and *The Biology and Neurophysiology of the Conditioned Reflex* (1967) for which he was awarded a Lenin Prize in 1972. He also wrote a life of Pavlov (1949), edited a number of collections of essays (the most recent being *Cybernetic Aspects in Studying Brain Action* (1970)), was Physiology Editor for the large and small medical encyclopaedias and contributed a preface to the Russian edition of R. Ashby's *Construction of the Brain*.

He was a member of the Executive Committee of the International Organisation for Brain Research, and represented his country at a number of international conferences, including the

International Congresses of Physiologists in Brussels, 1956), and Buenos Aires (1959), the International Organisation for the Study of the Brain (Paris, 1960) and the International Symposium on the Development of the Brain (USA, 1963). He was elected a member of the Academy of Medical Sciences of the USSR in 1945 and a member of the Academy of Sciences of the USSR in 1966.

Announcements

Appointments

Robert C. Seamans, jr., has been re-elected **President** of the **National Academy of Engineering.**

Awards

J. Erik Jonsson has been awarded the **Founders Medal** of the **National Academy of Engineering.**

Ivar Giaever has been awarded the **Vladimir K. Zworykin Award** of the **National Academy of Engineering.**

Corrigendum

In the article "New species of *Dryopithecus* from Kenya" by P. Andrews (*Nature*, **249**, 188; 1974), in the description of *Rangwapithecus*, a new subgenus of *Dryopithecus*, the type species of the new subgenus is the one first listed, namely *Dryopithecus* (*Rangwapithecus*) *gordoni*.

Erratum

In the article "The neurogenic and myogenic hypotheses in human (Duchenne) muscular dystrophy" by W. H. Thomson, J. C. Sweetin and R. A. Elton, (*Nature*, **249**, 151; 1974) in line 9 of the legend to Fig. 1, 33 should read 23.

APPOINTMENTS VACANT

GEOPHYSICIST

The Lamont-Doherty Geological Observatory of Columbia University announces a position with the seismology group as a Research Associate or Senior Research Associate. Candidates must have a strong background in seismic instrumentation and data analysis and will be expected to lead existing and initiate new programs of research involving observations of earth strain, tilt, and long-period seismic waves. Qualified candidates are invited to submit a résumé of their qualifications, publications, names and addresses of three references by August 15, 1974, to Dr. Lynn R. Sykes, Lamont-Doherty Geological Observatory, Palisades, New York 10964. Columbia University is an equal opportunity employer.

(2260)

CAMBRIDGE UNIVERSITY
DEPARTMENT OF GENETICS

Application are invited from microbial or molecular geneticists for a University Demonstratorship that is expected to be available from October 1, 1974, or sooner.

The scale of stipends from October 1, 1974 will be £2,247 a year rising by annual increments to £2,931 or, if the person appointed is resident in College, £2,148 rising to £2,832.

Further particulars may be obtained from the Secretary of the Appointments Committee of the Faculty of Biology 'A', Department of Applied Biology, Downing Street, Cambridge CB2 3DX, to whom applications should be sent before June 21, 1974. (2254)

UNIVERSITY OF GLASGOW
DENTAL HOSPITAL AND SCHOOL
RESEARCH ASSISTANTSHIP IN BIOCHEMISTRY

Applications are invited for a RESEARCH ASSISTANTSHIP in BIOCHEMISTRY, tenable for a period of three years from September or October 1974.

Candidates should have an Honours Degree in Biochemistry or an allied subject. There will be an opportunity to apply to register for a higher degree.

The work will involve a study of salivary proteins with a view to correlating abnormalities with pathological disorders. The project is financed by a grant from the Scottish Home and Health Department.

Salary Scale £1,500 to £1,650 per annum. F.S.S.U.

Applications, including curriculum vitae and names of two referees, should be sent to Dr. J. A. Beeley, Department of Dental Biochemistry, University of Glasgow Dental School, 378 Sauchiehall Street, Glasgow, G2 3JZ, from whom further information may be obtained. (2298)

CSIRO

AUSTRALIA

DIVISION OF MINERAL PHYSICS
NORTH RYDE, N.S.W.

RESEARCH SCIENTIST

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

FIELD: **ELECTROMAGNETIC GEOPHYSICS**

GENERAL: The Division of Mineral Physics, a constituent Division of the CSIRO Minerals Research Laboratories, carries out research directed towards the application of the techniques of physics to mineral exploration and exploitation.

The Division is establishing a rock magnetism laboratory to develop the application of magnetic techniques in mineral exploration and processing, and research into the practical applications of palaeomagnetism. The Division has established a low sensitivity and high field laboratory at North Ryde, and plans are well advanced for the construction of a high sensitivity laboratory in a nearby magnetically quiet environment.

DUTIES: Under the general direction of the leader, to extend research in field and laboratory projects related to: studies of the earth's past magnetic field, interpretation of magnetic anomalies, origin and extensions of ore bodies, anisotropy of remnance and susceptibility, magnetic cleaning techniques and structural analysis using remnance techniques.

QUALIFICATIONS: A Ph.D. degree in Geophysics, Geology or Physics or equivalent qualifications, supported by demonstrated research ability, with a sound knowledge of palaeomagnetic field and laboratory techniques. A good grasp of geological field problems is essential. Experience in opaque mineralogy, or chemical leaching, or magnetic anisotropy or high magnetic fields would be an advantage.

SALARY: The appointment will be made within the salary ranges of Research Scientist or Senior Research Scientist: $A9,380-$A14,290 p.a.

TENURE: An indefinite or a three year fixed term appointment may be negotiated. An indefinite appointment carries Australian Government Superannuation benefits.

Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 589/27 should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
64-78, Kingsway,
LONDON,
WC2B 6BD

by the 5th July, 1974.

Applications in U.S.A. and Canada should be sent to:—
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(2361)

The University of Birmingham

THE WELLCOME FOUNDATION LIMITED

Wellcome

Structure, Physiology and Biochemistry of Insect Neuromuscular Junctions

Applications are invited for a CASE postgraduate studentship in the above field of work.

The student will work primarily in the Department of Zoology and Comparative Physiology at Birmingham University with some time spent in the Unit of Arthropod Physiology at the Wellcome Research Laboratories, Berkhamsted Hill, where biochemical aspects of work in this field are currently in progress.

The Studentship commences on 1st October, 1974 and is tenable for 3 years. The current value of the Studentship is £695 per annum.

Further details may be obtained from the Academic Supervisor:

Dr. M. P. Osborne,
Dept. of Zoology & Comparative Physiology,
University of Birmingham,
Edgbaston, BIRMINGHAM.

(2362)

LISTER INSTITUTE OF PREVENTIVE MEDICINE

Elstree, Hertfordshire

BLOOD PRODUCTS LABORATORY

Recent graduate in microbiology required for control testing of human blood products and to assist in development work.

Please apply stating qualifications, age and experience to The Secretary, Lister Institute of Preventive Medicine, Elstree, Hertfordshire, from whom further particulars can be obtained.

(2374)

Graduate Required

Physics/Chemistry Graduate required for interesting research post within our Central Laboratories Division. The job is concerned with the creepage along and wetting of metal surfaces by liquids. The position is new and offers excellent scope for originality and innovation.

Undergraduates qualifying this year will be considered.

Research facilities and future prospects are good.

Location : North London.

Hours : 9 am to 5.15 pm (Mon to Fri) 36¼ hr. week.

Apply :

EVER READY®

Administration Manager,
Ever Ready (Holdings) Limited,
Central Laboratories,
St. Ann's Road,
London, N15 3TJ. Tel. No. 01-800 1101. (2244)

UNIVERSITY OF SOUTHAMPTON

FACULTY OF MEDICINE—MICROBIOLOGY

Applications are invited from suitably qualified science graduates for the post of LECTURER IN MICROBIOLOGY. The person appointed will be expected to undertake teaching and research duties in the field of microbial infections. Preference will be given to candidates with an interest in immunochemistry, virology or the chemistry of microbial structure.

Salary scale: £2,118 to £4,896. The initial salary will depend on qualifications and experience. Further particulars may be obtained from the Deputy Secretary's section (Ext. 353), The University, Southampton SO9 5NH to whom applications (7 copies from United Kingdom applicants) should sent not later than June 22, 1974, quoting reference be sent not later than June 22, 1974, quoting 58/74/L. (2249)

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF BIOCHEMISTRY

POSTGRADUATE RESEARCH

Research activities open to graduates wishing to work for the M.Phil. or Ph.D. degree include:

Yeast viruses: host-virus relationships.

Mycoviruses: characterisation and biochemistry of virus replication cycle.

Grants will be available to suitable candidates. Enquiries should be made to:

Dr K. W. Buck,
Department of Biochemistry,
Imperial College,
London SW7 2AY. (2262)

Kings

HEALTH DISTRICT (TEACHING)
Lambeth, Southwark and Lewisham Area Health Authority (Teaching)

Research Graduate

Graduate required to work on the Biochemistry of various hormones in women with benign or malignant tumours of the breast.

Application forms obtainable from the Personnel Office, King's College Hospital, Denmark Hill, London, S.E.5. Tel: 01-274 6222 Ext. 2726 (Miss Millwood) should be completed and returned by two weeks after date of insertion. (2251)

OXFORD UNIVERSITY

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of Research Assistant to work under Dr Malcolm Coe on the reproductive biology of Giant Tortoises on Aldabra Island in the Indian Ocean. The appointment will be for a period not exceeding three years, of which two years will be spent carrying out field work on Aldabra and one year in Oxford.

Applicants should be available to take up this post by the beginning of August 1974. Preference will be given to candidates with an interest or experience in the field of Herpetology. Salary will be by arrangement according to age, qualifications and experience.

Applications with a full curriculum vitae and the names of two referees should be sent immediately to the Secretary, Animal Ecology Research Group, Department of Zoology, South Parks Road, Oxford OX1 3PS. (2334)

UNIVERSITY OF LEICESTER

The Department of Botany has a vacancy for a Research Technician. Preference will be given to candidates who have HND or HNC in Applied Biology and some relevant experience. The person appointed will be involved in various researches in plant physiology, particularly those involving the aseptic culture of tissues and cells, and will be required to give general assistance in the Department and in the preparation of some laboratory classes. Salary on scale for Grade 3 Technicians, £1,650 to £1,920 (under review). Applications should be forwarded by July 31, 1974 to the Professor of Botany, The University, Leicester. (2346)

UNIVERSITY OF NOTTINGHAM
School of Biological Sciences
DEPARTMENT OF ZOOLOGY

Applications are invited from candidates with good honours degrees for a RESEARCH ASSISTANTSHIP, tenable for three years from October 1, 1974. An interest in tissue culture or neurobiology would be an advantage but is not essential. The successful candidate will be able to register for a higher degree of the University. Salary will be within the range £1,422 to £1,569.

Further details and forms of application, returnable not later than June 30, 1974, are obtainable from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham. Ref. No. 371. (2345)

RESEARCH IN CHEMISTRY

RESEARCH GRANTS will be available from October 1974, for graduate courses in Chemistry, leading to the degree of MSc or PhD for candidates with a 1st or 2nd class honours degree or equivalent.

Write for further information to the Senior Administrative Assistant, School of Chemical Sciences, University of East Anglia, University Plain, Norwich, NOR 88C. (2342)

UNIVERSITY OF SURREY
DEPARTMENT OF BIOLOGICAL SCIENCES
ASSISTANT EXPERIMENTAL OFFICER

Qualified man or woman required with knowledge of computing and statistical analyses for biological, microbiological or medical research. The successful applicant will participate in project planning and associated experimental work as well as being responsible for program writing and organisation of data (ICL 1905F computer). Salary: £1,929 to £2,223.

Further particulars can be obtained from the Assistant Secretary (Personnel), University of Surrey, Guildford, Surrey, GU2 5XH. Tel: Guildford 71281, Ext. 452, to whom applications in the form of a curriculum vitae, including the names and addresses of three referees should be sent to by June 28. Telephone enquiries will be welcomed by Professor Smith, on Guildford 71281, Ext. 687. (2340)

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF PLANT BIOLOGY

Applications are invited from graduates or from students expecting to graduate in 1974 with a first or upper second class honours in Plant Biology or a related subject for an S.R.C., C.A.S.E. Studentship to work on the effects of carbon dioxide and oxygen concentration on the metabolism of germinating barley. The project will be carried out in co-operation with Arthur Guinness, Son & Co. (Park Royal) Ltd., Park Royal Brewery, London, N.W.10. Candidates will be expected to register for a higher degree.

Applications (including a curriculum vitae and names of two referees) should be addressed as soon as possible to Professor S. L. Ranson, Department of Plant Biology, Ridley Building, The University, Newcastle upon Tyne NE1 7RU. (2339)

UNIVERSITY OF IBADAN
NIGERIA

Applications are invited for (a) SENIOR LECTURESHIP or (b) LECTURESHIP IN FOREST MENSURATION, INVENTORY AND AERIAL SURVEY in the Department of FORESTRY. Applicants must possess a post-graduate degree and have teaching and research experience in this field. Appointee will be expected to have close liaison with Federal and State Departments of Forestry and to advise governments on the inventory and management of High Forest and Plantations. Salary scales: (a) N5,030 to N5,750 p.a. (b) N2,760 to N4,830 p.a. (£1 sterling = N1.47.) The British Government may supplement salary in range £750 to £1,150 p.a. (sterling) for married appointee or £250 to £650 p.a. (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. These supplementation rates are currently under review. F.S.S.U. Family passages; various allowances; regular overseas leave. Detailed applications (two copies), including a curriculum vitae and naming three referees, should be sent by air mail, not later than June 27, 1974, to the Registrar, University of Ibadan, Ibadan, Nigeria. Applicants resident in U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars of these appointments may be obtained from either address. (2355)

CSIRO
AUSTRALIA
DIVISION OF MATHEMATICAL STATISTICS

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees — 2,100 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

GENERAL: The Organisation's Division of Mathematical Statistics has approximately 100 staff, including 60 professional scientists, located at centres and laboratories in capital cities and some major country towns. It is to be reconstituted as the Division of Mathematics and Statistics later in 1974 after the new Chief of the Division, Dr. J. Gani, takes up duties in Canberra.

CSIRO research in mathematics and statistics currently includes distribution theory, multivariate analysis, scientific inference and experimental design, and will be extended to include mathematical and stochastic modelling, geostatistics, optimisation, operations research and management science. Application of such research, relevant to agricultural, biological, industrial and physical investigations, currently includes design and analysis of experiments and models for ecological, environmental, agricultural and climatological systems and is being extended to include work on industrial processes and mineral surveys.

Professional scientists of the Division act as consultants in planning research and in the application of mathematics and statistics to investigations and experimental results.

RESEARCH SCIENTIST

POSITION NUMBER 440/270

FIELD: **MATHEMATICAL STATISTICS FOR MULTIVARIATE SURVEYS**

LOCATION: Highett, Victoria.

DUTIES: To conduct research into mathematical statistics related to the design and analysis of multivariate social and economic surveys, and applied research related to the mathematical and statistical aspects of the organisation's building and/or engineering research in the Melbourne region and to pursue individual research interests.

QUALIFICATIONS: Applicants should have a Ph.D. degree or equivalent qualifications with demonstrable research ability. Experience in statistical methodology for sociological, psychological or economic studies and in sample surveys of social attitudes would be an advantage.

SALARY: The appointment will be made within the salary range of Research Scientist: $A9,380-$A11,827 p.a., or Senior Research Scientist $A12,298-$A14,290 p.a. Consideration would be given to appointment of a suitably qualified applicant at a more senior level.

TENURE: This position is available for an indefinite period and Australian Government Superannuation benefits are available.

RESEARCH SCIENTISTS

POSITION NUMBER 440/271

FIELD: **GEOSTATISTICS & OPTIMISATION**

LOCATION: Melbourne, Victoria.

DUTIES: To conduct research into multivariate aspects of geostatistics and optimisation, and applied research in mathematical and statistical aspects of the organisation's minerals and/or geomechanics research in the Melbourne region and to pursue individual research interests.

POSITION NUMBER 440/272

FIELD: **BIOMETRICS AND STOCHASTIC MODELLING**

LOCATION: Prospect, N.S.W.

DUTIES: To conduct research into aspects of biometrics and stochastic modelling and applied research related to statistical and mathematical aspects of the organisation's animal physiology research in the Sydney region and to pursue individual research interests.

QUALIFICATIONS: A Ph.D. degree, or equivalent qualifications, with demonstrable research ability and experience in relevant fields of applied research.

SALARY AND TENURE: Appointments will be made within the salary ranges of Research Scientist: $A9,380-$A11,827 p.a. or Senior Research Scientist: $A12,298-$A14,290 p.a.

Either an indefinite or a three year fixed term appointment may be negotiated. An indefinite appointment carries Australian Government Superannuation benefits.

Applications quoting the appropriate Position Number and stating full personal and professional details, and the names of at least two professional referees should reach:—

The Personnel Officer,
Australian Scientific Liaison Office,
64-78, Kingsway,
LONDON,
WC2B 6BD

by the 12th July, 1974.

Applications in U.S.A. and Canada should be sent to:—
The Counsellor (Scientific),
Embassy of Australia, 1601 Massachusetts Avenue, N.W.,
WASHINGTON, D.C. 20036, U.S.A.

(2383)

Principal Biochemist (Pharmacologist)

Two Positions

National Biological Standards Laboratory

Canberra

Duties: Evaluate the pharmacological and toxicological aspects of new drugs from data submitted by drug companies. Report on animal studies carried out to support the proposed uses of drugs and make recommendations on their suitability and adequacy. Provide advice as required on problems concerning the pharmacology and toxicology of substances and the interpretation of experimental data. Carry out and direct research into the actions of drugs with particular reference to methods of drug evaluation and mechanisms of drug toxicity.

Qualifications: An appropriate degree in Science, Applied Science, or Medical Laboratory Technology; or equivalent qualification. Post graduate qualifications and broad experience in drug related fields are desirable.

Salary: $A12,911 to $A13,796 per annum. NB. exchange rate: £1 = $A1.60 approx.

Conditions: First class passage by air for the successful applicant and his dependants together with generous baggage allowances. Salary will be paid from date of embarkation. Four weeks annual leave, accumulative sick leave provisions and a comprehensive superannuation scheme are available.

Please write giving full details of qualifications and experience together with date and place of birth to:

The Recruitment Officer
Public Service Board
Canberra House
10/16 Maltravers St
London WC2R 3EH

By July 5, 1974 (2358)

THE OPEN UNIVERSITY

BIOLOGY TECHNICIAN (2B)

READVERTISEMENT

A vacancy exists for a BIOLOGY TECHNICIAN (GRADE 2B) in the Faculty of Science commencing as soon as possible. Main duties will include: assistance with course experimental work; the construction and servicing of biology summer school and day school equipment; general maintenance of services and equipment in the biology laboratories.

Applicants should possess O.N.C. or equivalent qualifications. Some workshop experience would be required and in addition, general biological laboratory experience would be useful.

Salary, based on qualifications and experience will be within the Grade 2B scale: £1,524 to £1,794 per annum.

Further details and application forms are available from the Personnel Manager (TS5), The Open University, P.O. Box 75, Walton Hall, Milton Keynes MK7 6AL. (Tel: Milton Keynes 74066, extn. 3068). Closing date for applications: Monday, June 24, 1974. (2416)

UNIVERSITY OF DURHAM

DEPARTMENT OF APPLIED PHYSICS AND ELECTRONICS

SENIOR DEMONSTRATOR

Applications are invited from graduates in electronic engineering or solid state physics for one or more posts of Senior Demonstrator. The duties will include some teaching and the supervision of either a first year Electronics Laboratory or a Physics of Materials Laboratory. Participation in research will be encouraged in either digital electronics or electronic materials science.

The post is tenable from October 1, 1974 for two years in the first instance renewable for a third and final year.

Salary on the scale £1,719 to £2,613 (under review) plus F.S.S.U. benefits.

Applications (three copies) naming three referees should be sent by June 21 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (2338)

UNIVERSITY OF DURHAM

DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the post of Postdoctoral Research Assistant from August 1, 1974 (or as soon as possible thereafter) to pursue research in Cosmic Ray Physics (Extensive Air Showers) involving measurements of the night sky Cerenkov radiation at the Haverah Park Air Shower experiment. Short periods of work in the United States may also be involved.

The appointment, which is funded by the Science Research Council, will be for a period of two years in the first instance, renewable for a third and final year.

Salary on the scale £1,866 to £2,586 (under review) with F.S.S.U. benefits.

Applications (three copies) naming three referees should be sent by June 24, 1974 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE from whom further particulars may be obtained. (2337)

THE UNIVERSITY OF MANCHESTER

LIBRARIAN/CURATOR

Applications are invited for the post of Librarian/Curator in the Department of Geology. The person appointed will look after maps and books in the departmental library, and will also be responsible for the care of the Department's teaching and research collection of rocks, minerals and fossils. Candidates should have, or expect to have shortly, a degree in geology, or a combined degree including geology. Initial appointment within the Graduate Assistant salary range p.a. £1,569 to £1,791 (under review). F.S.S.U. Further particulars and application form (returnable by June 28) from the Registrar, The University, Manchester M13 9PL. Quote ref: 116/74/N. (2351)

UNIVERSITY OF EXETER

DEPARTMENT OF PHYSICS

Applications are invited for a Postdoctoral Research Assistantship, supported by the Science Research Council, for theoretical work on fluid flow through distensible tubes, with a view to physiological applications in the fields of urodynamics and venous haemodynamics. Experience in theoretical elasticity, hydrodynamics or computing would be an advantage.

The appointment is for one year in the first instance, from October 1, 1974, and is renewable for a second year. Starting salary £1,929 (under review) plus F.S.S.U. Applications with the names of two referees, should be sent by July 12, 1974, to Dr. D. J. Griffiths, Department of Physics, University of Exeter, Exeter EX4 4QL (Telephone Exeter 77911, ext. 625), from whom further information may be obtained. Please quote 1/12/7072 in all correspondence. (2350)

UNIVERSITY OF NOTTINGHAM

CANCER RESEARCH CAMPAIGN LABORATORIES

IMMUNOLOGY OF CANCER

Applications are invited for postgraduate and postdoctorate posts to participate in research on immunological aspects of cancer under the direction of Professor R. W. Baldwin. Applicants for the postgraduate posts should have a good honours degree and there will be the opportunity to read for a higher degree. The postdoctorate appointment will be on the scale commencing at £2,118 per annum, and the postgraduate appointment will be on a scale £1,422 to £1,569.

Further details and application forms from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham. Closing date, June 30. Ref. No. 372. (2347)

THAMES POLYTECHNIC

SCHOOL OF ARCHITECTURE

LECTURER II IN BUILDING ACOUSTICS AND ENVIRONMENTAL SCIENCE

The School of Architecture invites applications from suitably qualified graduates to teach building acoustics and the application of environmental science to building. Applications from recently qualified graduates who have an interest in these fields will be welcomed.

The successful candidate will be a member of the teaching Division of Construction Technology, which is part of the Faculty of Architecture and Surveying, located at Hammersmith, London, W.6 and will also be associated with teachers of Physics and Materials Science at the Woolwich site of the Polytechnic. Personal interests and research will be encouraged. Duties will include teaching students on full-time diploma courses in Architecture (including acoustics to the final year) and C.N.A.A. degree courses in Surveying.

Salary scale: £2,700 to £3,474 plus £118 London allowance.

Further particulars and form of application may be obtained from the Secretary, Thames Polytechnic, Wellington Street, London SE18 6PF to whom completed applications should be returned by June 25, 1974. (2363)

INSTITUTE OF CANCER RESEARCH

ROYAL MARSDEN HOSPITAL, S.W.3

TECHNICIAN IN CYTOGENETICS

Required to work in a group studying chromosomes in malignant diseases of man. Previous experience in this or related field desirable. Qualifications required: University Degree in relevant subject, H.N.C., or AIMLT. Salary scale £1,440 to £2,292 plus London Weighting.

Apply in duplicate to the Secretary, 34 Sumner Place, SW7 3NU, with names of two referees and quoting ref. 301/B/522. (2349)

BIOCHEMIST

A position at the rank of Assistant Professor is available in the Department of Biochemistry, College of Medicine, University of Saskatchewan. Applicants must have a Ph.D. and/or M.D. degree and have training and interests in the area of nutritional biochemistry. Duties will include research and teaching of biochemistry and nutrition to undergraduate and graduate students. Effective date of appointment is negotiable. Salary will be commensurate with experience and training. Send curriculum vitae and names of three referees to Dr. J. D. Wood, Chairman, Department of Biochemistry, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N OWO. (2365)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF EARTH SCIENCES

CHAIR OF GEOPHYSICS

Applications are invited for a Chair of Geophysics to fill the vacancy which will arise on the retirement of Professor R. M. Shackleton from the Chair of Geology on September 30, 1975.

The salary will be not less than £5,973 a year. The University reserves the right to consider for appointment persons other than those who submit formal applications.

Applications (two copies) stating age, qualifications and experience and naming three referees should reach the Registrar, The University, Leeds LS2 9JT, from whom further particulars may be obtained (quoting reference 29/32) not later than August 31, 1974. Applicants from overseas may apply in the first instance by cable naming three referees who should preferably be in the United Kingdom. (2357)

CSIRO

AUSTRALIA

DIVISION OF ANIMAL PHYSIOLOGY, PROSPECT, N.S.W.

CHIEF OF DIVISION

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

GENERAL: Applications are invited from scientists who have an established record of personal research achievement and leadership for the position of Chief, Division of Animal Physiology. The vacancy will arise following the retirement of Dr I. W. McDonald later this year. The division has its headquarters at Prospect, approximately 20 miles from the city of Sydney. The Pastoral Research Laboratory at Armidale, N.S.W., the Beef Cattle Research Unit, at Townsville, Qld., and the Bloat Research Unit at Melbourne are regional units of the Division. The total divisional staff is approximately 150, including 55 professional staff.

The work of the Division currently includes research on ruminant nutrition, endocrinology, wool growth, climate physiology, energy metabolism, reproduction, and the pasture ecosystem. The primary objective of the Division is to provide knowledge that will improve productivity and efficiency of Australia's animal industries.

DUTIES: The Chief is responsible to the Executive for the conduct and direction of the research activities of the Division, for its general administration and for the control of funds available to it. The Chief is expected to formulate proposals for new research programmes in association with other scientists in Universities and State Departments and rural industry leaders.

The Chief of the Division of Animal Physiology is also a member of the Animal Research Laboratories Committee, of which Dr K. A. Ferguson is Chairman. The Committee has overall responsibility for the co-ordination of the research effort of the CSIRO Animal Research Laboratories, comprising the Divisions of Animal Health, Animal Physiology, Animal Genetics and Nutritional Biochemistry.

SALARY: Salary for the appointment will be the subject of negotiation but will be not less than $A22,875 p.a.

TENURE: Appointment to the Organisation will be for an indefinite period, and Australian Government Superannuation benefits are available. The tenure of Appointment as Chief could be subject to negotiation, but a fixed-term (of the order of 7 years) would be envisaged initially. Such an agreement could be renegotiated for a further period, or arrangements made for a transfer to a senior research position in the Organisation.

FURTHER INFORMATION: Dr A. E. Pierce, a Member of the CSIRO Executive, will be visiting Washington, U.S.A., from August 5 to 9, 1974 and London, England, from August 12 to 16, 1974, and will be available for discussions concerning the appointment with applicants and those interested in hearing more about the position. Those wishing to discuss the appointment should contact either the Chief Scientific Liaison Officer, Australian Scientific Liaison Office, 64 Kingsway, London, WC2B 6BD, England or the Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C. 20036, U.S.A. Scientists interested in discussing the appointment should ensure that the appropriate oversea office is contacted in ample time to enable suitable arrangements to be made and supply a brief curriculum vitae.

Further information on the Division's activities can be obtained by writing to the Secretary (Administration), CSIRO, P.O. Box 225, Dickson, A.C.T. 2602, Australia.

APPLICATIONS: Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 245/599 should reach:—

The Secretary (Administration),
Head Office, CSIRO,
P.O. Box 225,
DICKSON, A.C.T. 2602
AUSTRALIA.

Wellcome

Graduate Scientists

• A chance to change course

The Wellcome Foundation is a rapidly growing British owned international pharmaceutical organisation.

A vital link between our R & D activities and the world-wide distribution of the companies of the Wellcome group is the product registration department based at its London headquarters. Most countries of the world require new medical products to be registered for sale before marketing starts and this work is the responsibility of this department. It involves intelligent use of R & D reports and commercial and other information to meet the varied requirements of registration.

We are looking for a graduate chemist, pharmacist or biological scientist, probably less than 30, to join the department. This is a chance to move away from pure technical work and gain experience in an interesting and important sphere of this group's international activities.

In addition to an attractive salary the group offer excellent conditions of employment including assistance with relocation expenses where appropriate.

Please write giving brief career details and quoting reference U.127, to the Personnel Officer, Group Personnel Division, **The Wellcome Foundation Ltd.,** 183, Euston Road, London NW1 2BP.

university of wales
university college of swansea

READER IN BIOCHEMICAL ENGINEERING

Applications are invited for the above post tenable in the Department of Chemical Engineering.

The salary will be on the scale £4,368 to £5,406 per annum, together with F.S.S.U. benefits, increasing to £4,707 to £5,844 per annum, on October 1, 1974.

Further particulars may be obtained from the Registrar/Secretary, University College of Swansea, Singleton Park, Swansea SA2 8PP, to whom applications (10 copies) should be returned by **Monday, July 22, 1974.**

(2344)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF BOTANY

Applications are invited for a post of JUNIOR RESEARCH FELLOW in BOTANY, tenable from October 1, 1974, for one year in the first instance renewable for two further years. Salary £1,473 a year. Further particulars from the Registrar and Secretary, The University, Sheffield S10 2TN to whom applications (three copies) should be sent by July 5, 1974. Quote Ref. R.90/G. (2364)

BANTING AND BEST DEPARTMENT OF MEDICAL RESEARCH
UNIVERSITY OF TORONTO

Applications and nominations are invited for a faculty position at the rank of Associate or Full Professor to start on or prior to July 1, 1975. The applicant's area of research should be related to the molecular aspects of animal cell differentiation. Exceptional junior candidates may also be considered. Salary negotiable and commensurate with rank. Send curriculum vitae to :

Dr Alan G. Goodridge,
Search Committee Chairman,
Banting and Best Department of Medical Research,
University of Toronto,
112 College Street,
Toronto, Ontario M5G 1L6,
Canada. (2360)

IMMUNOLOGICAL TECHNICIAN

Required to work on various aspects of cell mediated immunity. Salary on Whitley Council Scale for Medical Laboratory Technicians, i.e. £1,440 to £2,292 p.a. plus £126 L.W. Applications and enquiries to Dr H. E. Amos, Department of Immunology, Institute of Dermatology, St. John's Hospital for Diseases of the Skin, Homerton Grove, London E9 6BX. Telephone: 01-985 7061. (2353)

UNIVERSITY OF NEW SOUTH WALES
PROFESSOR OF PASTORAL SCIENCES

Applications are invited for appointment to the above-mentioned chair in the School of Wool and Pastoral Sciences. The present head of School is Professor P. R. McMahon. Applicants should have experience in the scientific development and technology of the pastoral industry and its products and be capable of providing leadership in their particular fields of interest. Professional qualifications and/or research experience in areas such as animal production, range management, agricultural economics and pastoral agronomy are desirable. The professor will supervise and participate in teaching and examining undergraduate and postgraduate students in the School and engage in and promote research and advanced study in the field of his chair.

Salary $A19,614 per annum. Subject to the consent of the University Council, professors may undertake a limited amount of higher consultative work. The University reserves the right to fill any chair by invitation.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on **October 18, 1974.** (2356)

BASIC GRADE PHYSICIST

Required in the Radiation Physics Department of St. Bartholomew's Hospital. Duties include radiotherapy treatment planning, radiation dosimetry and computer programming. The successful candidate will be expected to undertake research and development work. Salary (depending on qualifications and experience) £1,497 to £2,259 plus London Weighting. Applications to Personnel Department quoting reference PTA/4544/N. (2397)

HAILE SELASSIE I UNIVERSITY
ETHIOPIA

Applications are invited for two posts of ASSOCIATE PROFESSOR/ASSISTANT PROFESSOR IN GEOGRAPHY. The first post is in Human Geography with reference to political and economic geography as well as rural development. The second post is in Physical Geography. The appointments are for two years from September 1974. Appointee to the first post will teach junior classes (40 - 50 students) in Location and Interaction Systems and senior classes (30 - 40 students) in Political Geography and Regional Planning for about nine contact hours a week. Appointee to the second post will teach second year classes (40 students) in Physical Geography, third year classes (40 students) in Techniques of Map Making and third year classes (30 students) in Soils and Biogeography for about eight contact hours a week. Salary scales: Associate Professor Eth.$13,200—Eth.$18,000 p.a. Assistant Professor Eth.$9,600—Eth.$14,400 p.a. (normally free of Ethiopian tax). (£1 sterling = Eth. $5.04). There may be supplementation of salary in range £1,100 to £1,275 p.a. (sterling) (normally free of all tax) and provision of children's education allowances and holiday visit passages. This supplementation rate is currently under review. Housing allowance; dependants allowance; family passages; baggage allowance.

Detailed applications (two copies), including a curriculum vitae and naming three referees, should be sent by airmail, not later than June 27, 1974 to the **Dean, Faculty of Arts, Haile Selassie I University, PO Box 1176, Addis Ababa,** send one copy to: **Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Ethiopia.** Applicants resident in U.K. should also Further particulars may be obtained from either address. (2369)

UNIVERSITY OF SURREY

DEPARTMENT OF CHEMICAL PHYSICS
NEW M.Sc. PROGRAMMES IN CHEMICAL PHYSICS

The Department of Chemical Physics invites applications for enrolment, in October 1974, into programmes in branches of Chemical Physics, leading to the degree of M.Sc. by examination and project.

Four programmes, Applied Crystallography, Crystal and Molecular Structure Determination, Crystallography and Spectroscopy, are offered, both full-time and by a day-release scheme. Applicants need not decide upon their choice of programme before the end of Term 1, as this term is common to all four programmes.

Entrance qualifications include a first degree in one of the physical sciences, or an equivalent qualification, such as Grad.R.I.C., or Grad.Inst.P.

Further details and application forms may be obtained from Dr G. A. Webb, Department of Chemical Physics, University of Surrey, Guildford, Surrey GU2 5XH.

(2341)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF BIOLOGY

Applications are invited for the post of lecturer in the Department of Biology. Candidates should have an appropriate Honours Degree and a research interest preferably in cytogenetics or cell culture. Opportunities exist for collaboration with the work of the Clinical Geneticist in the Faculty of Medicine. The lecturer will be expected to play a major part in teaching genetics to undergraduates in the Department of Biology and the Faculty of Medicine. Salary scale: £2,118 to £4,896. F.S.S.U. Initial salary will depend on qualifications and experience. Further particulars may be obtained from the Deputy Secretary's Section (Ext. 2400), The University, Southampton SO9 5NH to whom applications (seven copies from United Kingdom applicants) should be sent not later than July 12, 1974. Please quote reference number Na236/A. (2378)

THE HANNAH RESEARCH INSTITUTE
BIOCHEMISTRY DEPARTMENT

Scientific Officer required to assist with work on the metabolism of aromatic compounds by ruminant animals which will include the development of techniques for the quantitative assay of phenolic compounds in forage plants. Candidates should have a degree or HNC in chemistry or biochemistry. The appointment will have a starting salary within the range £1,435 to £2,329. Superannuation with a non-pensionable allowance of 5¼% to offset contributions.

Applications giving age, curriculum vitae, and the names of three referees should be forwarded to the Secretary, The Hannah Research Institute, AYR KA6 5HL by June 28, 1974. (2373)

NATIONAL VEGETABLE RESEARCH STATION
PLANT PHYSIOLOGIST

There is a vacancy for a Plant Physiologist in the grade of Scientific Officer to join a team concerned with development of new and improved systems of vegetable crop production. Degree in agricultural science, horticulture or agriculture, will normally be required: exceptionally a candidate with other equivalent qualifications will be considered. Experience in research work or commercial arable crop production is essential. Appointment in grade of Scientific Officer (£1,435 to £2,329 — under review) according to qualifications and experience. Superannuation. Full particulars and application form (to be returned by July 4, 1974) from the Secretary, NVRS, Wellesbourne, Warwick CV35 9EF. (2371)

UNIVERSITY OF THE WEST INDIES
TRINIDAD

Applications are invited for the following posts in the Faculty of Agriculture:—

1 SENIOR LECTURER/LECTURER or LECTURER/ASSISTANT LECTURER IN THE DEPARTMENT OF LIVESTOCK SCIENCE. Applicants should be graduates in Animal Science or Agricultural Science (with a major in Animal Science) with postgraduate qualifications in ruminant nutrition and physiology. Interest in animal production would be an advantage.

2 RESEARCH FELLOW/JUNIOR RESEARCH FELLOW IN THE DEPARTMENT OF AGRICULTURAL EXTENSION. Applicants should hold a postgraduate degree in extension education, sociology of rural sociology and should have training and experience in rural social research.

Salary scales: Senior Lecturer TT$17,304 — TT$25,824 p.a. Lecturer/Research Fellow TT$12,612—TT$20,316 p.a. Assistant Lecturer/Junior Research Fellow TT$10,200—TT$11,232 p.a. (£1 sterling = TT$4.8). F.S.S.U. Unfurnished accommodation for maximum of three years at 10% of salary, thereafter 20% of salary paid in lieu of housing. Family passages. Detailed applications (six copies), including a curriculum vitae and naming three referees should be sent by airmail, as soon as possible to the Secretary, University of the West Indies, St. Augustine, Trinidad. Further particulars will be sent to all applicants. (2370)

BIOCHEMIST

Preferably with experience of cell culture techniques, to join a research team investigating the enzymology of inherited metabolic disorders. Starting salary up to £1,581 plus £126 London Weighting p.a. Apply, enclosing curriculum vitae and two referees to Dr. A. D. Patrick, Reader in Chemical Pathology, Institute of Child Health, 30 Guildford Street, London WC1N 1EH, (2398)

CSIRO
AUSTRALIA

ANIMAL HEALTH LABORATORY, GEELONG
OFFICER-IN-CHARGE

The Commonwealth Scientific and Industrial Research Organisation has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 6,500 employees—2,100 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

LOCATION: The appointee will be located initially at Melbourne and subsequently at Geelong, Victoria.

GENERAL: Applications are invited from scientists who have an established record of personal research achievement and leadership, interested in the position of Officer-in-Charge, Animal Health Laboratory, Geelong. Experience in the specific field of veterinary virology is essential. Some knowledge of the major diseases exotic to Australian livestock and the management and direction of studies on these diseases, under conditions of maximum microbiological security, would be highly desirable.

The decision to establish the laboratory complex which will constitute the Animal Health Laboratory at Geelong was announced recently. The current estimated capital cost of the complex is expected to be $A56 million and spending, to begin in 1976/77, will be spread over five years. At full operation the Animal Health Laboratory, Geelong, will employ a staff of 170 including 25 scientists. Its initial annual operating costs would be approximately $A3 million.

The Laboratory will have a vital role in minimising the impact of the Australian livestock industry of an outbreak of an exotic disease, such as Foot and Mouth Disease, and will provide a facility for the diagnosis of exotic animal diseases. It will carry out special tests on biological material from livestock held in quarantine before entry into Australia. It will also carry out research on those virus diseases endemic in Australian livestock. The Laboratory will provide facilities for testing the safety and potency of vaccines that may be required for the control of exotic diseases and, should the necessity ever arise, for the production of Foot and Mouth vaccine.

The Animal Health Laboratory, Geelong will be administered and operated by CSIRO on behalf of the Australian Government. Following the establishment of the laboratory, a consultative committee will assist in the determination of priorities and will ensure effective liaison on policy matters. This committee will provide an essential link with the Animal Quarantine Branch of the Department of Health for the testing of livestock in the proposed off-shore High Security Animal Quarantine Station. The committee will also provide a liaison channel with the State Departments of Agriculture and for special research, training, diagnosis and epidemiology with the proposed Bureau of Animal Health in the Department of Primary Industry.

DUTIES: The Officer-in-Charge will be responsible to the Chief, CSIRO Division of Animal Health for the direction of the Animal Health Laboratory, Geelong. Initially, he will play a major role in the planning and construction of the complex and will make recommendations, through the Chief of the Division, to the CSIRO Executive concerning its future operation. Subsequently, he will be responsible for the conduct and direction of the work of the Laboratory. He will also be required to play a major role in developing close relationships with Commonwealth and State groups possessing common interests.

SALARY: Appointment will be made within the salary ranges of Senior Principal Research Scientist or Chief Research Scientist, Grade 1. $A18,077—$A20,750 p.a.

TENURE: It is envisaged that an appointment would be made for an indefinite period with Australian Government Superannuation benefits available, but consideration could be given to a fixed-term appointment.

FURTHER INFORMATION: Dr. A. E. Pierce, a Member of the CSIRO Executive, will be visiting Washington, U.S.A. from 5th to 9th August 1974, and London, England, from 12th to 16th August, 1974, and will be available for discussions concerning the appointment with applicants and those interested in hearing more about the position. Those wishing to discuss the appointment should contact either the Chief Scientific Liaison Officer, Australian Scientific Liaison Office, 64 Kingsway, London, WC2B 6BD, England or the Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C. 20036, U.S.A. Scientists interested in discussing the appointment should ensure that the appropriate oversea office is contacted in ample time to enable suitable arrangements to be made and a brief curriculum vitae should be supplied.

Further information on the Division's activities can be obtained by writing to the Secretary (Administration), CSIRO, P.O. Box 225, Dickson, A.C.T. 2602, Australia.

APPLICATIONS: Applications stating full personal and professional details, the names of at least two professional referees, and quoting Reference Number 201/449 should reach:—

The Secretary (Administration), CSIRO,
P.O. Box 225,
Dickson, A.C.T. 2602,
AUSTRALIA.

by the 6th September, 1974.
(2396)

Department of Agriculture

Applications are invited for a permanent and pensionable post in the Crop and Animal Husbandry Division, Northern Ireland.

The successful applicant will undertake work on pig production with special reference to increased efficiency, and will be required to undertake teaching duties in the Faculty of Agriculture, Queen's University, Belfast.

Appointments to the post may be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level, the qualifications for which are:

SSO Over 25 and under 32 years of age with a 1st or 2nd Class Honours Degree in Agriculture and at least 4 years post-graduate experience, preferably in relation to pig production.

HSO Under 30 years of age with an Honours Degree as above and at least 2 years relevant post-graduate experience.

SO Under 27 years of age with an Honours Degree as above.

Grading and commencing salary will be related to qualifications and experience on the following scales:

SSO £2,798 to £3,895
HSO £2,221 to £2,834
SO £1,435 to £2,329

Please write or telephone for an application form and further information, quoting Ref. SB 135/74/N to the Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232 44300, ext. 26). Completed forms must be returned to arrive not later than June 24, 1974.

(2419)

NORTHERN IRELAND CIVIL SERVICE

UNIVERSITY OF THE WEST INDIES
JAMAICA

Applications are invited for LECTURESHIP IN THE DEPARTMENT OF BIOCHEMISTRY. Duties of appointee will include lecturing and demonstrating to classes of undergraduates in both the Medical and Science Faculties. Salary scale: J$6,168 to J$9,768 p.a. (£1 sterling = J$2.20). F.S.S.U. Unfurnished accommodation at rent of 10% of salary, for maximum of three years, thereafter 20% of salary paid in lieu of housing. Family passages; triennial study leave. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Further particulars are available and should be obtained from the same source before an application is made.

(2409)

MEDICAL RESEARCH COUNCIL

TOXICOLOGY UNIT

Technical staff required for (a) histology laboratory and (b) biochemical laboratories. Candidates should possess A.I.M.L.T. or H.N.C. Med. Lab. Sciences for post (a) or H.N.C. Appl. Biol. for posts in (b). All posts within the categories of Technician or Junior Technical Officer. Salaries according to age and experience. Apply in writing to the Director, Medical Research Council, Toxicology Unit, Woodmansterne Road, Carshalton, Surrey. (2381)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF EARTH SCIENCES

Applications are invited for a post as RESEARCH ASSISTANT to work on the N.E.R.C. supported project "Palaeomagnetic Study of the African Crust" under the supervision of Dr J. Briden.

The main aims of this project are to extend the palaeomagnetic record back to 3300 m.y., and to test whether relative movements between adjacent cratons can be detected.

The appointee will be expected to register for a higher degree and submit a thesis on his contribution to the project. The appointment is for three years commencing as soon as possible and the salary will be equivalent to that of an N.E.R.C. Research Studentship.

Applications should be made to Professor J. G. Ramsay, Department of Earth Sciences, The University, Leeds LS2 9JT, naming two referees. (2386)

GREENWICH & BEXLEY AREA HEALTH AUTHORITY
BROOK GENERAL HOSPITAL
SENIOR TECHNICIAN—
NEUROPATHOLOGY

A vacancy exists in a new department which will deal with routine material from Neurosurgical and Neurological Units and research projects. The person appointed will be jointly responsible for implementing the services of the department.

Applications to :—

Senior Chief Technician,
giving age, experience and two referees
Brook General Hospital,
Shooters Hill Road,
Woolwich,
London, SE18 4LW. (2401)

SUNDERLAND POLYTECHNIC

SCHOOL OF PHARMACY AND BIOLOGY

RESEARCH ASSISTANTS

Applications are invited for Research Assistant posts in the following areas of study:

Biology: Ultrastructural studies of blue-green algae (Rivulariaceae).

Pharmaceutics: (a) Physical Pharmacy—adsorption, solubilisation and monolayer studies; tabletting and drug release.

(b) Microbiology—mode of action of antimicrobial agents; biodeterioration of pharmaceuticals.

Pharmacognosy: Chemotaxonomic and anatomical studies on medicinal plants;

Pharmacology: Allergy; gastric blood flow.

Successful applicants must have, or be about to obtain, a good honours degree (or the equivalent) and will be registered for M.Phil. and/or Ph.D. degrees of C.N.A.A.

Salary £1,500 by £81 (2) to £1,662 per annum (to be confirmed).

Further details and application forms may be obtained from the Personnel Officer, Sunderland Polytechnic, Chester Road, Sunderland SR1 3SD. (2393)

STANDARDS LABORATORY FOR SEROLOGICAL REAGENTS

Technician AIMLT (Bacteriology or Virology) or HNC in Medical Laboratory Sciences (Microbiology) required to work with Australia Antigen. Graduates may apply for this position.

Written applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (2392)

BIRKBECK COLLEGE
(UNIVERSITY OF LONDON)

Applications are invited for the post of LECTURER IN ZOOLOGY with teaching responsibilities at both undergraduate and M.Sc. levels. Salary scale incremental from £2,118 to £4,986 p.a. plus London allowance of £162 p.a. Initial salary on scale will not exceed £2,580 p.a. Further details and forms of application should be obtained from the Secretary, (N) Birkbeck College, Malet Street, London, WC1E 7HX. Closing date: July 1. (2390)

CONSULTOX LABORATORIES LTD.

188 Brent Crescent
London, N.W.10

VACANCY FOR CHIEF TECHNICIAN IN CLINICAL BIOCHEMISTRY/ HAEMATOLOGY DEPT.

Experience in both of the above fields essential, preferably in the field of animal toxicology. Experience in bacteriology also preferred, qualified up to H.N.C./B.Sc. with at least 5 years post-degree experience. Attractive hours, salary negotiable.

Apply to Dr B. P. Block, Director, Consultox Laboratories Ltd., 188 Brent Crescent, London, N.W.10. Tel. No.: 01-965 1157.

(2375)

UNIVERSITY OF DUBLIN
Trinity College

Lecturer in Clinical Microbiology

Re-Advertisement

Applications are invited for the above post. Candidates should have several years experience in Clinical Microbiology, but need not hold a medical qualification.

The post will entail duties in the teaching and research aspects of the subject and in the provision of a Microbiology service to the Federal Dublin Voluntary Hospitals.

It would be of particular interest to a person who is considering a career in Clinical Microbiology.

Salary scale: £2,867 by £162 to £4,001 (bar); £4,163 by £162 to £4,649; plus marriage and children's allowances and a non-contributory Pension.

Further particulars and application forms may be obtained from:

The Staff Secretary,
West Theatre,
Trinity College,
Dublin 2.

Closing date for completed applications is Friday, July 12, 1974. (2391)

For starting new research work the Laboratories of the "Institute for the Research on Alternative Methods to Animal Experiments" need, in Vienna or Munich, MEDICAL AND TECHNICAL SPECIALISTS **with very good knowledge of Tissue Culture.** Some knowledge of German required.

Applicants please write, with references to studies, present activities and salary, to: International Society for the Research on Alternative Methods to Animal Experiments, Austrian Section, A-1060, Vienna, Webgasse 42/3-. (2399)

THE CITY UNIVERSITY
LONDON
DEPARTMENT OF CHEMISTRY

Applications are invited for the

CHAIR OF ORGANIC CHEMISTRY

The salary will be in the range for professorial appointments (minimum salary, £5,973 p.a. on scales operative from October 1, 1974) and there will be a London allowance of £162 p.a. Superannuation will be in accordance with the provisions of the F.S.S.U.

Further particulars may be obtained from the Academic Registrar, The City University, St. John Street, London, EC1V 4PB.

The closing date for applications is July 31, 1974.

Please quote reference number 142/C/N. (AK2394)

THE ROYAL VETERINARY COLLEGE
(UNIVERSITY OF LONDON)

LECTURER IN PHYSIOLOGY

Applications are invited from veterinary, medical and science graduates for the post of Lecturer in Physiology. The main teaching responsibility is Veterinary Physiology for the B.Vet.Med. degree, but the appointee will also be expected to assist with the Honours B.Sc. course and to pursue research. Prospective applicants are encouraged to contact the Head of Department of Physiology, Professor M. G. M. Jukes.

Salary scale £1,929 to £4,548 p.a. (£2,118 to £4,896 from October 1, 1974) plus London Allowance £162. Initial salary determined by experience and qualifications. Superannuation benefits under FSSU.

Application forms and further particulars from the Assistant Secretary (Personnel), (N) The Royal Veterinary College, Royal College Street, London NW1 0TU. The appointment is intended to become effective as near the beginning of October 1974 as can be arranged.

Closing date for applications July 5, 1974. (2388)

BP

Research in Offshore Exploration

With expansion of our offshore exploration activity, the following vacancies have arisen within the Exploration and Production Research Division at our Sunbury Research Centre.

Oceanic Geophysicist/Geologist

to study offshore seismic and other data from deep water areas. He will be aged under 35, have a good honours degree in Physics, Geology or Geophysics, and have at least five years' experience in marine geological and/or geophysical studies, preferably in deep water. He should be familiar both with the equipment used for reflection, refraction, gravity and magnetic surveys and in the processing and interpretation of results. Interest in recent developments in crustal research and/or sedimentary processes on the continental margins would be an advantage.

Marine Geophysicists

to work on surveys in connection with the engineering characteristics of the sea (currents and waves) and the sea bed (sediment type, thickness, etc.). A considerable amount of operational survey work is involved but the development of improved techniques will be a significant element.

Candidates aged under 35, should preferably hold an M.Sc. in Applied Geophysics or Marine Geotechnics. One post requires at least 5 years' experience in the supervision and interpretation of sea bed surveys using sparker, boomer and side-scan sonar equipment. The other requires less experience but a specific interest in equipment development.

Starting salaries will be competitive and will depend on age and experience. First class fringe benefits include a non-contributory pension scheme, subsidised lunches and full sports and social facilities.

■ Please write for an application form, quoting reference U.819, to: The Manager, Central Recruitment, the British Petroleum Company Limited, Britannic House, Moor Lane, London EC2Y 9BU. (2423)

RESEARCH OFFICER IN MATERIALS SCIENCE

Research Officer S.R.C. sponsored required to study solid state electrochemical systems involving oxide bronzes and fast ion conductors. There will be a strong emphasis on practical applications. Candidates with training in Physical Chemistry, or Solid state device fabrication would be especially suitable.

The appointment is tenable for three years from October 1, 1974. Salary will depend upon age and qualifications of the candidate up to £2,715 per annum, with two increments to £3,045 (London allowance included), scale under review.

Applications with curriculum vitae and names of two referees should be sent by July 1, 1974 to Dr Mino Green, Electrical Engineering Department, Materials Section, Imperial College, London SW7 2BT.

Enquiries please phone 589-5111, Ext. 2025.

(2402)

CHELSEA COLLEGE
UNIVERSITY OF LONDON

The Biophysics Laboratory has a vacancy for a LABORATORY TECHNICIAN GRADE 2B. The appointment of a trainee technician would be considered. The work involves research into electrical properties of biological materials and general teaching laboratory duties. Qualifications required are O.N.C. or equivalent, but two A-levels in appropriate Science subjects would be preferable; encouragement will be given for further study. Salary Scale: £1,699 to £1,969 per annum (including London Allowance) or for a trainee £973 to £1,426 per annum (including London Allowance). Please write, giving personal details, to Dr. D. Rosen, Biophysics Laboratory, (N) Chelsea College, Manresa Road, London, SW3 6LX. (2389)

UNIVERSITY OF THE WEST INDIES
JAMAICA

Applications are invited for CHAIR IN THE DEPARTMENT OF MATHEMATICS. This is one of two Chairs. Appointee should have broad interests and considerable research experience in Pure or Applied Mathematics and will be expected to participate in the direction of teaching and research carried out in the Department. Salary scale: J$12,336 to J$15,768 p.a. (£1 sterling = J$2.20). F.S.S.U. Unfurnished accommodation at rent of 10% of salary for maximum of three years, thereafter 20% of salary paid in lieu of housing. Family passages; triennial study leave. Detailed applications (10 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Detailed particulars are available and should be obtained from the same source before an application is made. (2408)

BIOMETRICIAN

Applications are invited for a permanent and pensionable post in the Biometrics Division of the Department of Agriculture, Northern Ireland. The successful candidate will be concerned mainly with the following;

(1) design and analysis of laboratory and field experiments and surveys;
(2) the statistical assessment of genetical studies on poultry, cattle and herbage plants;
(3) the development and application of computer based systems for handling scientific and other data associated with research and development in Agriculture.

The successful candidate may be required to undertake teaching duties in the Faculty of Agriculture, The Queen's University, Belfast.

Appointment to the post may be at Senior Scientific Officer, Higher Scientific Officer or Scientific Officer level, the qualifications for which are:

SSO Over 25 and under 32 years of age with a first or second class Honours Degree or equivalent in mathematics or biology with specialisation in and/or experience of statistics with special reference to the design and analysis of experiments and surveys. Candidates at this level should have at least 4 years relevant post-graduate experience.

HSO Under 30 years of age with an Honours Degree as above and at least 2 years relevant post-graduate experience.

SO Under 27 years of age with an Honours Degree as above.

Grading and commencing salary will be related to qualifications and experience on the following scales:

SSO £2,798 to £3,895 HSO £2,221 to £2,854 SO £1,435 to £2329

Please write or telephone for an application form, quoting Ref. SB 136/74/N to the Secretary, Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 0232-44300, ext. 26). Completed forms must be returned to arrive not later than June 28, 1974.

NORTHERN IRELAND CIVIL SERVICE (2420)

DUNSTAFFNAGE MARINE RESEARCH LABORATORY

OBAN, ARGYLL

SCIENTIFIC OFFICER

Applications are invited for the post of Scientific Officer to join a multidisciplinary group working on the breakdown of cellulose in marine sediments. The applicant would be expected to have a University degree or equivalent in Microbiology or related science. Post would be for initial period of two years; starting annual salary around £1,435.

Application forms can be obtained from the Director, Dunstaffnage Marine Research Laboratory, P.O. Box 3, Oban, Argyll PA34 4AD. (2387)

CHAIR OF PHARMACOLOGY

Medical college and large teaching hospital in major medical centre is considering applications for the Chair of Pharmacology. Rush-Presbyterian-St. Luke's Medical Center is an equal opportunity/affirmative action employer. Please send curriculum vitae and bibliography to Dr William Knospe, Chairperson of the Pharmacology Search Committee, Rush-Presbyterian-St. Luke's Medical Center, c/o Department of Medicine, 1753 West Congress Parkway, Chicago, Illinois 60612 U.S.A. (2405)

INSTITUTE OF MEDICAL LABORATORY TECHNOLOGY

Applications are invited for a vacancy in the editorial and information office.

Ideally the successful candidate will have had experience in a medical laboratory (and preferably hold medical technology qualifications and/or a science degree) and in addition some editorial or other office experience. Duties are likely to include editorial and advertising work on a monthly and other publications, liaison with printers and providing an information service to enquirers, for example members of the profession and school leavers.

Salary negotiable around £2,000.

Office is situated in central London convenient to the Underground.

Applications, giving brief curriculum vitae, to the General Secretary, Institute of Medical Laboratory Technology, 12 Queen Anne Street, London W1M 0AU, marked CONFIDENTIAL. (2404)

THE UNIVERSITY OF ADELAIDE

invites applications for appointment as

LECTURER

in

ANATOMY AND HISTOLOGY

A medical qualification registrable in South Australia is desirable but not essential. The appointment will be made as soon as the person concerned is able to assume duty.

The Department of Anatomy and Histology teaches University students of Medicine, Dentistry and Science, and in addition Physiotherapy and Occupational Therapy students of the South Australian Institute of Technology (for further particulars see Statement referred to below). Research fields are neuroendocrinology, human and comparative neurology, cell biology, experimental embryology, and clinical anatomy. Persons with an interest in clinical anatomy (medical graduates) or neuroendocrinology are especially invited to apply.

SALARY SCALE: $A8,698 by $A470(1) by $A469(6) to $A11,982 (plus a loading for medical qualifications at the rate of $A833 a year); with superannuation on the F.S.S.U. basis. Initial salary will be fixed within the scale in accordance with qualifications and previous experience.

FURTHER INFORMATION, including list of particulars required in an application, is available from the Registrar of the University or from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

APPLICATIONS should reach the Registrar, G.P.O. Box 498, Adelaide, South Australia, 5001 not later than **July 31, 1974.** (2407)

THE UNIVERSITY COLLEGE OF WALES

ABERYSTWYTH

DEPARTMENT OF BOTANY AND MICROBIOLOGY

Applications are invited for the post of DEMONSTRATOR, tenable from October 1, 1974. Applicants should have a special interest in Ecology.

Salary range: £1,758 to £1,923 per annum.

Application forms and particulars available from the Registrar. Closing date: June 28, 1974. (2380)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

There is an opening for a research assistant in a new small paediatric research laboratory which will undertake special investigations mainly into intestinal malabsorption.

Salary according to qualifications and experience within the range £1500-£2000 a year.

Applicants who wish to visit should make an appointment with Mrs. Colvin (Paediatric Secretary) 748 2050 Ext. 2034.

Applications in writing with full details of qualifications and experience and names of two referees to The Secretary, Charing Cross Medical School, Fulham Palace Road, London, W6 9HH by 24th June 1974 quoting reference Paed/HB. (2422)

RESEARCH IN MUSCLE DISEASE

Applications from honours graduates in biochemistry or a related discipline are invited for the post of Research Assistant in continuing studies of muscle metabolism in health and disease.

The successful applicant will be expected to register for the degree of Ph.D. at the University of Glasgow. The post carries N.H.S. grading, with appropriate superannuation and salary (£1,797 to £2,259) from October 1, 1974.

Applications naming two referees should be sent as soon as possible to Dr W. H. S. Thomson, Research Laboratory, Knightswood Hospital, Glasgow G13 2XG. (2428)

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF PHYSICS

RESEARCH ON SUPERFLUID HELIUM 3 BELOW 3 mK.

Applications invited for the post of Postdoctoral Research Assistant to work on the above topic under the direction of Professor H. E. Hall. The post is for two years from October 1st, 1974 or earlier; salary on the Lecturer scale (initially £2,412 p.a. for an applicant of 26 or over). Candidates with experience of experimental work below 100 mKare preferred. Curriculum vitae, publications list, and names of two referees should be sent to Professor H. E. Hall, Schuster Laboratory, The University, Manchester, M13 9PL. (2421)

POSTDOCTORAL RESEARCH ASSISTANT

required in Department of Clinical Pharmacology for work on the effect of drugs on the adrenal cortex. Previous experience with tissue culture and subcellular fractionation techniques would be an advantage. Appointment for up to 3 years. Salary, commensurate with experience, will be in non-clinical Lecturer range. Apply, The Secretary, St Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref. CPG. (2465)

UNIVERSITY OF AUCKLAND

NEW ZEALAND

LECTURESHIP IN MECHANICAL ENGINEERING

Applications are invited for the above-mentioned post from candidates wth qualifications in the areas of control engineering and dynamics; industrial thermodynamics; production engineering. Previous experience in research, in teaching and professional practice are all desirable but it is not essential that applicants should have experience in all three.

The salary scale for a Lecturer in NZ$6753 rising to $8568 p.a., commencing salary being determined in accordance with qualifications and experience.

Further particulars including details of superannuation, travel expenses, application procedure, are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on **8 July 1974.** (2414)

UNIVERSITY OF MALAWI

CHANCELLOR COLLEGE

Applications are invited for LECTURESHIP IN PHYSICS, tenable from 1 September 1974. Applicants should have a higher degree, preferably a Ph.D. with some teaching and research experience. Their theoretical or experimental research interests should include acoustics, solid state and vacuum physics. The appointee will be expected to teach at all levels of a four-year ordinary degree course. Salary scale (including expatriate addition): K2,809-K4,714 p.a. (£1 sterling = K2.01). Salary may be supplemented either by a University addition of K720 p.a. (taxable in Malawi) or the British Government may supplement salary by £600-£850 p.a. (sterling) for married appointee or £300-£550 p.a. (sterling) for single appointee (normally free of all tax) and provide children's education allowances and holiday visit passages. These latter supplementation rates are currently under review. Gratuity of 15%-25%; superannuation scheme transferable with F.S.S.U.; Family passages; various allowances; biennial overseas leave; housing. Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be forwarded by airmail not later than 4th July, 1974, to the Registrar, University of Malawi, University Office, P.O Box 278, Zomba, Malawi. Applicants resident in U.K. should also send 1 copy to Inter-University Council, 90/91 Tottenham Court Road, London, W1P 0DT. Further particulars may be obtained from either address. (2418)

BIOCHEMIST

A leading British pharmaceutical Research Organisation has a vacancy for a SENIOR BIOCHEMIST to initiate and direct research projects in the areas of pharmacokinetics, drug metabolism, molecular pharmacology and enzymology in association with the design and development of new medicines. Persons with apropriate experience are invited to apply in writing for further details, to: The Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB, marking the envelope CONFIDENTIAL. (2450)

UNIVERSITY OF WESTERN AUSTRALIA

PERTH

ANATOMY

Applications are invited for appointment as SENIOR LECTURER OR LECTURER in the Department of Anatomy. The University wants to appoint an anatomist interested in new educational methods, particularly in the teaching of gross anatomy and in the clinical applications of anatomy. The Department is well equipped for teaching and research, and is housed in a pleasant modern building. There are ten full-time academic staff and active research programmes in tissue regeneration, neurobiology, cytology, embryology and various aspects of human biology. The appointee will be encouraged to develop his research interests and train research students. Further information on the Department may be obtained from Professor D. B. Allbrook.

The salary ranges are: Senior Lecturer—$A12,268 to $A14,308 p.a.; Lecturer—$A8,698 to $A11,982 p.a. Benefits include superannuation similar to F.S.S.U., fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and housing loan scheme.

Applications in duplicate stating full personal particulars, qualifications and experience should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009, by **June 30, 1974.** Candidates should request three referees to write immediately to the Staffing Officer. (2415)

UNIVERSITY OF EAST ANGLIA

SCHOOL OF CHEMICAL SCIENCES

Applications are invited for Science Research Council Advanced Course Studentships to read for the

M.Sc. IN CHEMICAL SPECTROSCOPY

This one-year course, commencing October 1, 1974, covers a wide range of spectroscopic techniques and includes practical research experience. Applicants must possess at least a 2nd class honours degree or the equivalent. Application forms and further information may be obtained from the Senior Administrative Assistant, School of Chemical Sciences, University of East Anglia, Norwich NOR 88C. (2413)

HEDGES AND BUTLER LTD.

Microbiologist

We are seeking a graduate Microbiologist to provide an efficient and complete mycological and bacteriological service to our Central Laboratory situated in our major production and packing complex at Bromley-by-Bow.

Although primarily a quality control function some applied research together with development of existing methods is envisaged. Self motivation and initiative are essential.

Applicants, male or female, will probably be in the age bracket 24-35 and will possibly already have had three or more years industrial experience. An Upper Second in Microbiology is the minimum degree level required and a higher degree would be advantageous.

This position offers an excellent opportunity to a person interested in furthering management skills whilst retaining contact with the latest technical developments in this field.

Good conditions of employment and other benefits including free life assurance and a contributory pension scheme will apply. A good salary will be negotiated which will reflect the importance of this appointment.

Please write with a detailed curriculum vitae, including details of age, experience and current salary to: Miss J. Long, Personnel Department, Hedges and Butler Limited, Three Mill Lane, Bromley-by-Bow, E.3 or alternatively telephone 01-980 7133 for an application form.

(2400)

Section Leader — Quality Control

John Wyeth and Brother Limited, a major pharmaceutical company situated at Havant, Hants, has a vacancy for a Section Leader within their well equipped Quality Control laboratories. The successful applicant will be responsible to the Head of Chemical Control for the efficient operation of the raw materials and intermediates section and preferably will possess H.N.C. in Chemistry, together with at least three years analytical experience in the pharmaceutical or allied industries.

Conditions of employment are excellent. The Company offers a non-contributory Pension and Life Assurance Scheme and assistance with re-location expenses is given where necessary.

Please apply in writing to:—

Cameron Wolstenholme,
Director of Personnel and Industrial Relations,
John Wyeth and Brother Limited,
Huntercombe Lane South,
Taplow,
Maidenhead,
Berks, SL6 0PH.

Wyeth

(2467)

STEROID CHEMIST

The Radiochemical Centre Limited is a leading world supplier of radioactively labelled compounds for research in the life sciences. Expansion of our production work has created a vacancy for an experienced steroid chemist.

Applicants should have an honours degree and relevant experience in synthetic steroid chemistry.

We expect to make the appointment with a starting salary of up to £3,000 according to previous experience. Staff conditions include a contributory superannuation scheme, generous leave allowance, canteen and social club. Assistance with house purchase may be available.

Telephone Little Chalfont 4444 or write to the Personnel Officer for an application form.

The Radiochemical Centre

Amersham Bucks

(2470)

Education Overseas

Sudan

Lecturer/Instructor—Biology Laboratory Techniques

At the Institute of Laboratory Technicians, Khartoum Polytechnic, to teach (Lectures and Practicals) in Biology Laboratory Techniques. Applicants, aged 30-50 should be AIST or equivalent with technical teaching qualifications and experience in the prescribed duties of the post. Appointment for 3 years.

Salary in excess of current UK earnings plus a tax free overseas allowance. Other benefits include free family passages, paid leave, children's education allowances, and free accommodation and medical attention. Superannuation rights may be safeguarded; all emoluments paid by British Government. Applicants should normally be citizens of, and permanently resident in, the United Kingdom.

For full details and an application form please apply stating age, qualifications and experience to:—

Appointments Officer

Overseas Development Administration

Room 317
Eland House
Stag Place
London SW1E 5DH

(2458)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

Research Assistants (2) required for Endocrine Laboratory to join projects studying effects of hormones on the chemistry of cells, and the application of these studies to clinical investigation. Salary according to qualifications and experience, but the posts are junior, and suitable for new graduates. Applications to Dr J. R. Daly, Department of Chemical Pathology, Charing Cross Hospital Medical School, London W6 8RF, from whom further particulars may be obtained. (2426)

GRIFFITH UNIVERSITY

BRISBANE, AUSTRALIA

SCHOOL OF AUSTRALIAN ENVIRONMENTAL STUDIES

Griffith University will admit its first undergraduate students in March 1975. Its organisation is on a broad school of study basis and it has a commitment to interdisciplinary teaching. Applications are now invited from men and women for the following positions:

SENIOR LECTURER/LECTURER IN POLITICAL ECONOMY

Applicants should have a major interest in regional development or regional economics with relevant practical experience. The successful appointee will have qualifications in one or more of the fields of economics, geography, political science or administration. The School would be especially interested in an applicant who has combined some of these disciplines with teaching and research work.

LECTURER IN APPLIED MATHEMATICS

The appointee will be expected to assist in planning and developing a main study area in system science and applicable mathematics. This will include the study of applied mathematics with emphasis on mathematical methods and operations research. Some experience in the presentation of mathematical ideas to students with limited formal mathematical background would be an advantage.

Salaries will be within the range: Senior Lecturer —$A12,268 to $A14,308; Lecturer—$A8,698 to $A11,982. Rates of exchange as at May 1974 are $A1 = 62p; $A1=$US1.48.

Appointments to these positions will be from October 1, 1974, or as soon as possible thereafter.

For further details of these posts and for the method of application, write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (2443)

TECHNICIAN required by Department of Experimental Immunology of INSTITUTE OF CANCER RESEARCH, Clifton Avenue, Belmont, Sutton, Surrey. Duties include maintenance and transplantation of animal tumours (training will be given), general animal husbandry and supervision of juniors. Would suit animal technician washing to learn more general laboratory techniques. Applicants with A.I.A.T., A.I.S.T., preferred. Home office licence an advantage. Starting salary in region £1566-£1770 according to qualifications and experience. Apply in duplicate with names of two referees to the Secretary, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/523. (2435)

UNIVERSITY OF THE WITWATERSRAND,

JOHANNESBURG, SOUTH AFRICA

SENIOR LECTURER IN MATHEMATICS

Applications are invited for appointment to the above post in the Department of Mathematics. Duties are to be assumed on January 1, 1975, or earlier by mutual arrangement. Candidates should have a strong research interest in some field of modern pure mathematics.

Salary will be in the range R7,245 to R9,315, the initial salary to be determined according to qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy, if eligible.

Intending applicants should obtain the information sheet relating to this post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than June 30, 1974. U.K. applications may obtain the information sheet from the London Representative, University of the Witwatersrand, 278 High Holborn, London, W.C.1, to whom a copy of the application should be sent. (2430)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(UNIVERSITY OF LONDON)
DEPARTMENT OF NUCLEAR MEDICINE

RADIOIMMUNOASSAYIST

An experienced Biochemist (preferably post-doctoral) or medical graduate with a special interest in radioimmunoassay and saturation assay techniques is required to take charge of the service/development group in the Department of Nuclear Medicine. Responsibilities will include the oversight of routine work currently undertaken within the Department and by peripheral research groups, but special emphasis will be placed on the development of new and improved assay techniques. This is a new appointment offering a challenging opportunity to an imaginative and energetic scientist in a group with a long experience of R.I.A. methods and possessing excellent technical facilities. The successful applicant will be expected to participate in the undergraduate and postgraduate teaching. Salary on the Lecturer scale according to age, qualifications and experience £1,929 to £4,548 per annum plus £162 London allowance, rising on October 1, 1974 to £2,118 to £4,896 per annum plus London allowance. Applications including a curriculum vitae and the names and addresses of two referees should be submitted to Professor R. Ekins (N), The Middlesex Hospital Medical School, London W1P 7PN, by July 1, 1974. Further particulars may be obtained similarly by ringing 01-636 8333, Extn. 7289). (2446)

THE POLYTECHNIC OF CENTRAL LONDON SCHOOL OF ENGINEERING AND SCIENCE BIO-ORGANIC GROUP

RESEARCH FELLOW

£2,151 to £2,421

for work on the enzymology of penicillin production in penicillium chrysogenus. Candidates should have, or expect to obtain a Ph.D. in Enzymology or Protein Chemistry.

RESEARCH ASSISTANT (2 posts)
£1,427 to £1,592

(a) for work on the entry of drugs into mammalian cells in culture; (b) for work on hydrolytic enzymes capable of degrading the natural macromolecules present in sewage disposal systems.

Candidates for both posts should have, or expect to obtain a good Honours degree in Biochemistry or related subjects. Successful candidates may be registered for a higher degree of the CNAA.

Details and application form from The Establishment Officer, 309 Regent Street, London W1R 9AL. (2457)

THE MALAYSIAN RUBBER PRODUCERS' RESEARCH ASSOCIATION

requires an experienced ELECTRON MICROSCOPE TECHNICIAN to take charge of the operation and maintenance of its Siemens Elmiskop Mk 1 and ancillary equipment. The position is suitable for candidates aged between 25 and 35 with experience in biological and physical work and with a sound knowledge of replica embedding and sectioning techniques. The starting salary may be between £1,400 and £2,400 per annum depending on age, experience and qualifications. There is a pension scheme.

The Association will be moving in July to an attractive new location on a 30-acre site at Brickendonbury, near Hertford. Transport from Welwyn Garden City and locality may be provided.

Please write giving details of qualifications and experience to:

The Director,
The Malaysian Rubber Producers' Research Association,
56 Tewin Road,
Welwyn Garden City,
Herts. (2439)

Product Registration— Pharmaceuticals

As a major and successful U.K. based pharmaceutical manufacturer with world-wide interests, our activities and markets continue to expand. This expansion, coupled with new legislation, creates the need to appoint an additional graduate to join the Product Registration Department in Nottingham.

Responsibilities will consist of assistance in the preparation of submissions for registration of pharmaceutical products in the U.K. and overseas countries and in the preparation of technical dossiers for use in various departments of the Company. Liaison with marketing and technical specialists is an integral part of the job.

Applications are invited from graduates in pharmacy or a biological science who have worked in the pharmaceutical industry for about two years. Previous experience in product registration would be an advantage but is not essential.

Employment conditions are first class. Some help with relocation expenses will be given if appropriate. Please write for an application form to: J. F. Pattison, Employment Services Dept.

Boots

The Boots Co. Ltd.,
Station Street,
Nottingham NG2 3AA.

(2468)

Pharmacologist/ Neurochemist

We are looking for an experienced Biochemically orientated Pharmacologist or Neurochemist to join a multi-disciplinary team seeking novel drug therapy for mental illness.

He (or she) will probably possess a Ph.D and preferably have post-doctoral experience, but in any event should have substantial research experience concerning the Biochemistry of the central nervous system.

The person appointed will be expected to take responsibility for important areas of the project work and will work in close collaboration with scientists specialising in behavioural and electro-physiological techniques.

Salary will be competitive and there are good fringe benefits. The site is located one mile from Harlow New Town and Development Corporation property may be available to suitable candidates at economical rent.

If you would like to be considered for this post, please write, outlining your career to date, to:

BRL

John Atkinson,
Site Personnel Officer,
Beecham Research Laboratories,
The Pinnacles,
Harlow, Essex.

BRL 1972.

(2427)

Research in Surface Physics

A graduate Physicist or Electronics Engineer is required to join a team working on fundamental investigations of the thermal oxidation of silicon and the electrical properties of the silicon/oxide interface. Modern surface-physics electronic-measurement and computer-analysis techniques are used and the applicant will be expected to make electrical measurements and assist in their interpretation. A sound knowledge of semiconductor physics and electronic systems is essential and experience in electronic design, computer programming or UHV techniques would be an advantage.

We are situated on the attractive Surrey/Sussex border in close proximity to London, the South Downs and the Coast. Working conditions, salaries and conditions of employment are first class.

Mullard Research Laboratories

Application forms may be obtained from M. L. Malpass, Personnel Manager, Mullard Research Laboratories, Cross Oak Lane, Salfords, Nr. Redhill, Surrey. Ref. 358/N

(2438)

AGRICULTURAL RESEARCH INSTITUTE OF NORTHERN IRELAND
Hillsborough, Co. Down

ASSISTANT EXPERIMENTAL OFFICER

Applications are invited for the post of Assistant Experimental Officer to assist with experimental work with beef animals.

Salary scale: £1,435 to £2,329 plus Superannuation Allowance.

Candidates should possess—a pass degree; H.N.D.; or O.N.D. in Agriculture, or equivalent.

Previous experience of supervisory duties and working with animals would be an advantage.

Application forms and further particulars may be obtained from the Secretary to whom applications should be submitted by Monday, July 8, 1974.

Canvassing will disqualify. (2403)

UNIVERSITY OF PAPUA AND NEW GUINEA

Applications are invited for the Post of CHIEF TECHNICIAN, AGRICULTURE, tenable as soon as possible. Appointee should have a degree in Agriculture or equivalent qualification with appropriate research experience. Responsibilities will include supervision and assistance in research work, and the preparation of materials for examinations and practices. Salary: A$9,099 to A$10,432 p.a. plus A$360 p.a. dependant allowance (£1 sterling = A$1.62). Housing allowances. Applications (2 copies) including a curriculum vitae, a recent small photograph, an indication of starting date, and naming three referees should be sent by airmail to arrive as soon as possible to the Secretary, P.O. Box 4820, University, Papua New Guinea, from whom further particulars may be obtained. (2431)

SCIENTIFIC OFFICER/ HIGHER SCIENTIFIC OFFICER

required at the Agricultural Research Council Unit of Statistics, Edinburgh, to advise on application of existing statistical methods to agricultural research and to take part in the development of new methods.

QUALIFICATIONS: A good Honours degree in Mathematics or Statistics together with appropriate postgraduate statistical experience.

SALARY: Scientific Officer scale £1,435 to £2,329. Higher Scientific Officer scale £2,221 to £2,854 depending on qualifications and experience, a minimum of two years postgraduate experience being required for appointment to the HSO grade.

The post is superannuable, with an allowance to offset contributions. Enquiries and applications to the Director, Agricultural Research Council Unit of Statistics, 21 Buccleuch Place, Edinburgh EH8 9LN. (2442)

KINGSTON POLYTECHNIC
SCHOOL OF GEOLOGY
SENIOR TECHNICIANS
(1) FOR MINEROLOGY AND PETROLOGY SECTION
(2) FOR STRUCTURAL GEOLOGY SECTION

A degree in Geology or Advanced Certificate for Science Lab technicians or several years' appropriate experience desirable. Salary grade 3/4 £1,521 to £2,031.

Further details and application forms from Assistant Registrar, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. (2424)

UNIVERSITY OF THE WEST INDIES
JAMAICA

Applications are invited for (a) LECTURESHIP or (b) ASSISTANT LECTURESHIP IN THE DEPARTMENT OF PHARMACOLOGY. Duties of the post will be to instruct students in Pharmacology reading for the MB, BS degree of the University, and to do research in Pharmacology. Preference will be given to candidates with medical qualifications. Salary scales: (a) (Medical) J$7,860 to J$10,752 p.a. (Non-medical) J$6,168 to J$9,768 p.a.; (b) (Medical) J$6,300 to J$6,900 p.a. (Non-medical) J$5,006 to J$5,486 p.a. (£1 sterling=J$2.20). F.S.S.U. Unfurnished accommodation at rent of 10% of salary, for maximum of 3 years, thereafter 20% of salary paid in lieu of housing. Family passages; triennial study leave. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible, to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Further particulars are available and should be obtained from the same source before an application is made. (2434)

MANCHESTER AREA HEALTH AUTHORITY (TEACHING)
SOUTH DISTRICT
WITHINGTON HOSPITAL
MANCHESTER M20 8LR
GRADUATE

required with a good honours degree in biochemistry. The appointee will take part in research into thrombosis and development work in the National Reference Laboratory for Anticoagulant Control Reagents at Withington Hospital.

Further information can be obtained from Dr. L. Poller, Consultant Haematologist, Withington Hospital.

Applications with the names of two referees to the Hospital Secretary, quoting ref. B22. (51323) (2453)

UNIVERSITY OF THE WEST INDIES
JAMAICA

Applications are invited for (a) LECTURESHIP or (b) ASSISTANT LECTURESHIP IN THE DEPARTMENT OF ZOOLOGY, tenable as soon as possible. Preference will be given to persons with an interest in Marine Ecology. Salary scale: (a) J$6,168 to J$9,768 p.a.; (b) J$5,006 to J$5,486 p.a. (£1 sterling=J$2.20). F.S.S.U. Unfurnished accommodation at rent of 10% of salary for maximum of three years, thereafter 20% of salary paid in lieu of housing. Family passages; triennial study leave. Detailed applications (6 copies), including a curriculum vitae and naming 3 referees, should be sent by airmail, as soon as possible to the Registrar, University of the West Indies, Mona, Kingston 7, Jamaica. Detailed particulars are available and should be obtained from the same source before an application is made. (2433)

UNIVERSITY OF EXETER
Demonstratorship in Organic Chemistry

Applications are invited for a Demonstratorship in Organic Chemistry, tenable from 1 October 1974 for two years. Applicants should have a Ph.D. degree or equivalent research experience.

Salary within the range £1941-£2247 per annum with initial placement in accordance with qualifications and experience. The post is superannuable (FSSU).

Further particulars may be obtained from: The Secretary of the University, Northcote House, The Queen's Drive, Exeter EX4 4QJ, to whom applications (six copies; overseas applicants one copy), together with the names of two referees, should be sent by 15 July, 1974. Please quote Reference No. 1/12/7074 in all correspondence. (2436)

UNIVERSITY OF THE WITWATERSRAND,
JOHANNESBURG, SOUTH AFRICA

BERNARD PRICE INSTITUTE FOR PALAEONTOLOGICAL RESEARCH

VACANCY: SENIOR RESEARCH OFFICER/RESEARCH OFFICER

Applications for the above position are invited from the persons whose research interests lie in the fields of palaeobotany and/or palynology. Experience in the field of Gondwana palaeobotany is preferred, but will not be an essential condition of appointment. The level of appointment will depend on the appointee's qualifications and experience.

Salary will be in the following ranges:

Senior Research Officer: R7,245 to R9,315.

Research Officer: R5,520 to R7,935;

the initial salary to be determined according to qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy, if eligible.

Intending applicants should obtain the information sheet relating to this post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, with whom applications should be lodged not later than July 31, 1974. U.K. applicants may obtain the information sheet from the London Representative University of the Witwatersrand, 278 High Holborn, London, W.C.1, to whom a copy of the application should be sent. (2429)

UNIVERSITY OF MALAYA
FACULTY OF SCIENCE

Applications are invited for the posts of LECTURER/ASSISTANT LECTURER in the Departments listed below. Subject to academic suitability and experience, preference will be given to candidates who are competent in Bahasa Malaysia (Malay). Candidates should have at least a good honours degree with suitable teaching and research experience in addition to the special qualifications where indicated. For the Lectureships, a doctorate is normally required.

DEPARTMENT OF GEOLOGY (One post). Applicants should have a higher degree in Geology and be qualified in Palaeontology/Stratigraphy.
SCHOOL OF BIOLOGICAL SCIENCES:

One post in the field of LOWER PLANT PHYSIOLOGY. Preference will be given to the candidate who possesses a good knowledge of the Metabolism and Morphogenesis of Lower plants.

One post in the field of QUANTITATIVE ECOLOGY/BIOMETRICS. Candidates should have a sound biomathematical background with suitable teaching and/or research experience in aspects of quantitative ecology such as population estimation and dynamics, distribution patterns, association and community analysis, and systems analysis.

One post in the field of SOIL MICROBIOLOGY. Special interests in one or more of the following areas:- (1) decomposition of organic materials (2) nitrogen fixation (3) bio-degradation of pollutants.

One post of Lecturer/Assistant Lecturer to be in charge of the UNIVERSITY OF MALAYA FIELD STUDIES CENTRE for the School of Biological Sciences. Candidates should have at least a good honours degree with interest and research experience in Field Biology. Administrative experience would be an advantage.

One post in the field of BIOLOGY OF VASCULAR CRYPTOGAMS with special interest in research, particularly in ferns, mosses or other cryptogamic groups of the Malesian flora.

Salary scales (approx. stg. equivs.): Lecturer £1524-2441; Asistant Lecturer £1330-1460 p.a. In addition the folowing allowances are payable: Variable Allowance £243 min. £649 max. p.a. calculated at 35% of basic salary. Supplementary Housing Allowance £503 p.a. and medical benefits.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is **15 July, 1974.** (2444)

CHEMISTRY DEPARTMENT
UNIVERSITY COLLEGE LONDON

There is a vacancy for the post of POST-DOCTORAL RESEARCH ASSISTANT sponsored by the S.R.C. to work on the kinetics, stereochemistry and mechanism of oxidatively-induced reactions of organotransition metal complexes. Appointment for one year, salary £1,929 plus £162 London Allowance (under review). Please write to Mr F. Widdas, Chemistry Department, University College, 20 Gordon Street, London WC1H 0AJ. (2447)

Ministry of Agriculture, Fisheries and Food
Plant Pathology Laboratory, Harpenden

Plant Scientist

■ **To work in team engaged on cereal disease surveys** ■ **Research into the epidemiology of plant diseases** ■ **Develop techniques for disease assessment** ■ **Disease forecasting and appraisal of crop losses** ■ **Opportunity for individual investigation.**
□ Degree or equivalent in Plant Science or related subject □ Interest in quantitative aspects of plant pathology essential □ Experience or interest in the use of computers an advantage □ Age under 30 □ Appointment as Higher Scientific Officer (£2283-£2916) or Scientific Officer (£1497-£2391) according to age and experience □ Salaries under review □ Ref: SB/4/AG.

Ministry of Agriculture, Fisheries and Food
Salmon and Freshwater Fisheries Laboratory, London

Zoologist/Physiologist

■ **To initiate and conduct research into fish migration and 'homing' problems** ■ **Study reactions of fish to altered river conditions resulting from large-scale water transfers** ■ **Liaise with other organisations.**
□ 1st/2nd hons degree or equivalent in Zoology or Physiology □ At least 4 years' postgraduate experience □ Background in Zoological/Physiological research in fisheries desirable □ Age under 32 □ Appointment as Senior Scientific Officer (£3088-£4185 under review) □ Ref: SB/2/AK.
□ Application forms (to be returned by 8 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Science group
CIVIL SERVICE

(2448)

ROBERT GORDON'S INSTITUTE OF TECHNOLOGY, ABERDEEN

School of Pharmacy

LECTURER
IN PHARMACEUTICAL CHEMISTRY

Relevant academic, industrial or research experience required.

Salary in range £1,733-£4,173 per annum.

Details from Director, Robert Gordon's Institute of Technology, Schoolhill, Aberdeen, AB9 1FR.

(2462)

Glamorgan Polytechnic

POLITECHNIG MORGANNWG

Research

Applications are invited from suitably qualified persons for positions as Research Assistants or Research Students for projects in the following Faculties:—

Engineering (including Mining);

Science;

Social Sciences and Arts (including Management and Business Studies).

Particular vacancies exist for work on

(a) The fracture of concrete;

(b) The electrical properties of carbon impregnated plastics;

(c) The microbial degradation of coal.

The appointments will be for an initial period of two years but will normally be extended for three years. The persons appointed will be required to register for a Higher Degree of the Council for National Academic Awards. They will be expected to hold a good Honours Degree or a similar qualification. Applications from candidates with some experience in employment since graduation will be particularly welcome. The salary will be £1,500 for research assistants. For research students the payment will be similar to SRC scales but some additional income may be available.

Applications, to be returned by 5th July, should be made by letter stating age, qualifications, educational background, experience and specific field of interest to:

The Secretary (Reference VN), Glamorgan Polytechnic, Llantwit Road, Treforest, Pontypridd, CF37 1DL. Telephone: Pontypridd 0443-405133.

(2464)

Reckitt & Colman
PHARMACEUTICAL DIVISION

Mass Spectroscopist

We are seeking the services of a chemist or biochemist to operate a gas chromatograph—mass spectrometer within the Spectroscopy Section of the Analytical Services Department. The successful candidates will be responsible for running and maintaining an LKB 2091 GC-MS instrument and the development of mass spectroscopy for the determination of structures of reaction intermediates, contaminants of drug candidates, and metabolites of potential drugs undergoing toxicological and clinical evaluation.

Preferred candidates will have had experience in GC-MS either in the pharmaceutical or related industry or a university.

Contributory pension and bonus schemes are in operation, and the Company offers 4 weeks annual holiday, together with excellent social and welfare facilities.

Please apply giving details of qualifications, experience and career to date to: Mrs P A Haynes, Staff Personnel Officer, Reckitt & Colman, Dansom Lane, Hull HU8 7DS.

(2437)

OXFORDSHIRE AREA HEALTH AUTHORITY (TEACHING)

RESEARCH INSTITUTE, CHURCHILL HOSPITAL, HEADINGTON, OXFORD OX3 7LJ

RESEARCH TECHNICIAN

required to assist in our investigation of the effects of radiation on the vascular system of the central nervous system. Previous laboratory experience desirable but not essential. Further details from Dr. J. W. Hopewell, Research Institute, Churchill Hospital, Oxford; applications to The Secretary of the Board of Management, Research Institute. (2469)

UNIVERSITY OF GLASGOW LECTURESHIP IN VIROLOGY

Applications are invited for a Lectureship in the Department of Virology. Candidates should have research experience with bacteriophage. The new salary scale for Lecturers is £2,118 to £4,896 per annum, which will be effective from October 1, 1974, initial salary placement will be within the range £2,118 to £3,285 per annum. F.S.S.U.

Applications (eight copies) should be lodged not later than June 28, 1974, with the undersigned, from whom further particulars may be obtained.

In reply please quote Ref. No. 3443/IM.

ROBT. T. HUTCHESON, Secretary of the University Court. (2451)

CENTRAL BIRMINGHAM HEALTH DISTRICT
THE CHILDREN'S HOSPITAL
PRINCIPAL AND SENIOR GRADE BIOCHEMIST

The Clinical Chemistry Department of the Children's Hospital gives a Regional Paediatric service and offers experience in a wide range of Biochemical techniques, including screening and research into inherited metabolic disease. The appointment of the successful candidate will depend on previous hospital experience, qualifications, and ability to deputise for the Consultant Chemical Pathologist. Salary:— Principal £3,969 to £5,175; Senior £2,964 to £3,843.

For further information please contact Dr. D. N. Raine (telephone 021-454 4851), to whom applications giving personal details and the names of two referees should be sent. The Children's Hospital, Ladywood Middleway, Fiveways, Birmingham B16 8ET. (2452)

BROOM'S BARN EXPERIMENTAL STATION

HIGHAM, BURY ST. EDMUNDS, SUFFOLK IP28 6NP

A ZOOLOGIST

is required as SBREC Fellow at Broom's Barn (which is a unit of Bothamsted Experimental Station). The subject of study is bird and small mammal pests of sugar beet.

Qualifications—1st or 2nd class honours degree, but those graduating in 1974 will be considered. The fellowship is for three years and will enable a suitably qualified applicant to register for a higher degree. The salary scale will be related to the first three points of the Scientific Officer scale: £1,435 x £84 to £1,519 x £97 to £1,616 (scale under review). Superannuation under FSSU with a 4½% non-pensionable allowance to offset personal contribution.

Applications should be sent by July 11, 1974, to the Head of the Station, from whom further particulars can be obtained. (2460)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS AL5 2JQ

ASSISTANT STATISTICIANS

to analyse and interpret data from agricultural and other biological experiments using the Station's computer. Degree, HNC or equivalent qualification in mathematics or statistics. Some knowledge of agriculture or biology an advantage.

Appointment in grade of Scientific Officer (£1,435 to £2,329). Starting salary according to qualifications and experience. Superannuation with non-pensionable allowance to offset contributions.

Apply in writing to the Secretary giving names and addresses of two referees and quoting reference 2262 by July 11, 1974. (2461)

Administrative Assistant

County Environment Department

The South Yorkshire County Council places great emphasis on the importance of the total environment and has established a separate Environment Department, headed by a Chief Officer. The Department is responsible for initiating and carrying into effect, in accordance with the Council's overall corporate policies, active programmes for the improvement of the environment in South Yorkshire.

Applications are invited for the following post in the Assessment Division of the Department

ENVIRONMENTAL SCIENTIST £3,273 to £3,729

The officer appointed will work within a multi-disciplinary team engaged on research and the formulation of the County Council's Environment Policy. The team, in consultation with local and national authorities, will identify the causes and extent of environmental and ecological damage and advise the County Council on policies for remedial action and future protection.

In particular, the officer will be responsible for the assessment of the natural environment of South Yorkshire and will recommend policies for the protection of areas of scientific importance in the County. He, or she, will be involved, within the corporate approach adopted by the Department, as a point of reference on planning application, protection and improvement schemes proposed by the Department.

The post will be attractive to graduates in natural sciences with experience in assessment techniques and the management of the countryside, including areas requiring environmental protection or improvement and sites of scientific interest.

Please write or telephone for an application form, quoting Post Ref: V40 to the Chief Executive (Personnel), South Yorkshire County Council, Regent Street, Barnsley S70 2TN. Telephone Barnsley 86141 Ext. 13.

Closing date for applications will be: 25 June 1974.

South Yorkshire County Council

The post is advertised after consultation with the Local Government Staff Commission and is not restricted to Local Authority staff, although other things being equal, preference will be given to Local Government Officers serving in England (excluding London) and Wales. (2463)

UNIVERSITY OF LEEDS

DEPARTMENT OF GENETICS

A TECHNICIAN (GRADE 3)

is required for assistance in research in the above department. Familiarity with chemical biochemical and/or microbiological techniques would be a decided advantage. Candidates should have at least 2 'A' levels plus some 'O' levels plus 3 years relevant experience, or comparable qualifications. The work would not be inappropriate for graduates. Salary on the scale £1,650 to £1,920 per annum. Replies to Professor J. R. S. Fincham, Department of Genetics, University of Leeds, Leeds LS2 9JT. (2449)

CHEMIST/BIOCHEMIST

To take part in a study of bile Salt Metabolism in Diabetes and Thyroid Diseases.

Project suitable for thesis. Training will be provided for techniques necessary for the project.

Salary £1,900.

Apply in writing to Dr. G. H. Tomkin, M.D., F.R.C.P.I., F.A.C.P., Dept. of Endocrinology, Dudley Road Hospital. Box 293, Birmingham B18 7QH. Quote ref. 549/N. (2459)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY COLLEGE OF NORTH WALES, BANGOR

SCHOOL OF PHYSICAL AND MOLECULAR SCIENCES

POSTDOCTORAL RESEARCH FELLOWSHIP IN CHEMISTRY

Applications are invited for an S.R.C. Postdoctoral Fellowship to work in collaboration with Professor C. J. M. Stirling on mechanistic studies of carbanions in solution.

The salary will be in the range £2,118 to £2,247 per annum plus F.S.S.U., and the Fellowship will be tenable from October 1, 1974, or such other date as may be arranged.

Applications (two copies), giving details of qualifications, research experience, and the names and addresses of two referees, should be sent as soon as possible to the Secretary and Registrar, University College of North Wales, Bangor, from whom further details may be obtained. (2348)

THE UNIVERSITY OF MANCHESTER

C.A.S.E. STUDENTSHIP IN CHEMICAL METALLURGY

Applications are invited for an S.R.C. studentship leading to the Ph.D. degree for work on the recovery and separation of metals by hydrochlorination and hydropyrolysis reactions. The work will be carried out in the Department of Metallurgy and in the Metals Extraction Division, Warren Spring Laboratory, D.T.I. Stevenage. Applicants should possess or expect to obtain a good honours degree or an M.Sc. in Metallurgy or Chemistry and have a strong interest in extractive metallurgy or physical inorganic chemistry. Conditions in accordance with S.R.C. regulations. Applications to Dr. R. A. J. Shelton, Department of Metallurgy, The University, Manchester, M13 9PL (2343)

UNIVERSITY OF BIRMINGHAM

Department of Pharmacology (Preclinical) and MRC Neuropharmacology Unit

POSTGRADUATE RESEARCH STUDENTSHIPS

Applications are invited for 2 research studentships supported by the Medical Research Council, commencing on 1 October 1974. The research work of the Department and Unit covers various aspects of the pharmacology of the central nervous system with special reference to the mode of action of drugs, and there are opportunities for learning new techniques such as microiontophoresis, radiochemical assay and zonal centrifugation.

Applicants should have a 1st or upper 2nd Class Honours degree in pharmacology, biochemistry, physiology or related biological subjects.

Applications, in writing to:

Professor P. B. Bradley,
Dept. of Pharmacology (Preclinical),
Medical School,
Birmingham,
B15 2TJ (2273)

WESTFIELD COLLEGE

(UNIVERSITY OF LONDON)
DEPARTMENT OF BOTANY AND BIOCHEMISTRY

S.R.C. CASE STUDENTSHIP

For work on the effect of phosphorous concentration on competition between planktonic algae and on the interactions between phosphorus and other inorganic nutrients involved in the eutrophication of surface waters. The work will be in collaboration with the Unilever Research Laboratory at Port Sunlight where the student will spend a minimum of one month per year

N.E.R.C. RESEARCH STUDENTSHIP

For work on "Water and ion movement in live **Sphagnum** and peat". About 2% of the earth's surface is covered by peat and the ecology of one of the major peat forming plants is to be studied.

Both studentships are available from October 1974. Applicants should have, or expect to obtain a 1st or upper 2nd class honours degree in a Biological Science, although consideration will be given to graduates in Physical or Chemical Science who have a keen interest in biological systems.

Apply by July 15 to Mrs B. Thake (CASE) or Dr R. S. Clymo (NERC), Westfield College, Kidderpore Avenue, Hampstead, London, NW3 7ST. (2354)

UNIVERSITY OF SOUTHAMPTON ELECTROCHEMICAL TECHNOLOGY

Applications are invited for Postdoctoral Fellowships and Postgraduate Studentships from suitably qualified scientists and engineers who wish to join a multidisciplinary group working on long term studies of energy storage systems, metal recovery, novel chemical syntheses and pollution control.

Further details are obtainable from Dr. R. E. W. Jansson, Department of Chemistry. The University, Southampton SO9 5NH. (2412)

ULSTER: THE NEW UNIVERSITY

SCHOOL OF BIOLOGICAL AND ENVIRONMENTAL STUDIES

RESEARCH STUDENTSHIPS IN LIMNOLOGY

Applications are invited for two research studentships tenable at the Limnology Laboratory of The New University of Ulster.

1. To study the initial stages of colonisation of a large artificial lake to be filled in the near future with storm water discharge from the new city of Craigavon. The study will have a management-orientated bias and will be primarily concerned with aspects of the physics, chemistry and biology of the open water. The grant is for two years and the candidate will be expected to register for the M.Phil. degree.
2. To study the zooplankton of Lough Neagh with particular emphasis on grazing and re-cycling of nutrients. The successful candidate will be expected to contribute to the work of a small group comparing limnological conditions in Lough Neagh with those inside a large Lund-type butylite enclosure set in the lough.

The grant is for three years and the candidate will be expected to register for a D.Phil. degree.

Both grants, financed by the Northern Ireland Department of the Environment, will be at Research Council rates.

Application forms and Further Details should be obtained from The Registrar, The New University of Ulster, Coleraine, Northern Ireland (quoting Ref: 74/82) to whom completed applications, including the names and addresses of two referees, should be returned not later than 5th July, 1974. (2382)

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF CHEMISTRY

Applications are invited for the following:

1. POSTDOCTORAL RESEARCH FELLOWSHIP for studies on chemical carcinogenesis. The appointee will join a team working on chemical and biochemical aspects of polycyclic aromatic hydrocarbon binding to DNA, ranging from synthetic and structural organic chemistry to tissue culture. Candidates should hold (or except to gain) a Ph.D. in organic or biological chemistry and experience in nucleic acid chemistry is desirable but not essential. The appointment is from October 1, 1974 or a date to be arranged until September 30, 1975 at a salary not less than £1,923 per annum plus F.S.S.U.

2. AN S.R.C. (C.A.S.E.) STUDENTSHIP for a project involving the synthesis of a novel group of heterocyclic compounds. These are designed to possess controlled chemical reactivity and potential herbicidal character. The work will be carried out in conjunction with I.C.I. Plant Protection Limited and part of the programme will be performed at their Jealott's Hill Research Station. Applicants should have (or expect to obtain this summer) a good Honours degree or G.R.I.C. in chemistry and the successful will be expected to register for a Ph.D.

Applications for either of the above, including a curriculum vitae and names and addresses of two referees to: Dr. G. M. Blackburn, Department of Chemistry, The University, Sheffield S3 7HF (from whom further information is available in respect of the Studentship). (2352)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF AERONAUTICS AND ASTRONAUTICS
COMBUSTION HEAT TRANSFER

Applications are invited for a Research Fellow at post-doctoral level to work on a Science Research Council sponsored continuing programme concerned with the measurement and prediction of heat transfer from simulated combustion systems. The experimental programme utilises the department's shock tube facilities and involves modern techniques for heat transfer measurement.

The appointment, which requires relevant postgraduate experience, is for one year but may be extended until January 31, 1976. Salary will be in the range £1,929 to £3,048 (under review) plus F.S.S.U. benefits.

Applications, giving details of age and relevant background and quoting the names of two referees, should be made to the Deputy Secretary's Section, The University, Southampton SO9 5NH, as soon as possible. Please quote reference number: Na/238/R. (2376)

YORK UNIVERSITY
POSTDOCTORAL FELLOWSHIP

A Fellowship will be available in one of the following areas:

1. Laboratory studies of small particles using laser techniques.
2. Low temperature matrix isolation spectroscopy.

Applicants should have a strong experimental background in aerosol physics or chemistry, low temperature spectroscopy, or laser applications.

Salary to $8,700 p.a. Contact Dr. W. W. Duley, Physics Department, York University, Toronto, Canada. (2367)

UNIVERSITY OF SOUTHAMPTON
RESEARCH STUDENTSHIP IN CRYOGENICS

Applications are invited for a three-year Research Studentship sponsored by A.E.R.E., Harwell, to study the condensation behaviour of cryogenic fluids. A large cryogenic rig has been constructed at A.E.R.E. for this project. Condensation studies will be confined, at first, to nitrogen, but will lead on to binary and multicomponent fluids to model the condensation of LNG in large plant. Successful applicants will be required to register for a higher degree of the University.

Applicants should have a First or Upper Second Class degree in Physics or Chemical Engineering, or equivalent qualification, and should write, together with the names of two referees, to the Academic Registrar, The University, Southampton SO9 5NH. (2379)

RESEARCH STUDENTSHIPS BASIC AND MOLECULAR ANIMAL VIROLOGY
INSTITUTE OF VIROLOGY, THE UNIVERSITY OF GLASGOW, GLASGOW

Two further research studentships for British Nationals will be available from October 1974 for graduates with a first or at least an upper second class honours degree in a biological science who wish to work for a Ph.D. The Institute is well equipped, has a large scientific staff and the current research programme covers the following fields:

•Virus-specified nucleic acids and proteins; genetics and physiology of mammalian viruses; tumour virology; electron microscopy of cells, viruses and nucleic acids; genetics of mammalian cells.

Applicants should send a curriculum vitae and the names and addresses of three academic referees to Professor J. H. Subak-Sharpe at the above address. (2372)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF PHYSICS
RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Research Fellowship in Theoretical Physics for an investigation of Gauge Symmetries in High Energy Physics. The precise experience of applicants is not crucial but familiarity with the study of symmetries in Elementary Particle Physics is essential. The Fellowship is tenable for up to two years nine months from October 1, 1974, and the initial salary will be on a range up to £2,223 plus F.S.S.U. benefits. Further particulars may be obtained from Miss J. Hodgson, Department of Physics, and applications should be sent to Mr. D. A. S. Copland, Secretary and Registrar's Department, The University, Southampton SO9 5NH, to arrive by July 5, 1974. Please quote ref: Na237/R. (2377)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF DENTAL SCIENCES

Applications are invited for a M.R.C. postgraduate studentship for work related to the combined effects of mechanical stress and the physiological environment on the performance of dental and surgical prosthetic materials.

Candidates must possess a First or Upper Second Class Honours Degree in Materials Science or a related subject and the successful applicant will be expected to register for a higher degree.

Applications, together with the names of two academic referees, should be received not later than July 5, 1974, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote reference RV/276064/N. (2385)

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF BOTANY

Applications are invited for a Postdoctoral Fellowship established under a grant from Country Kitchen Foods Ltd., Churchill, Somerset, for pursuit of research on virus diseases of the cultivated mushroom, as a continuation of work already in progress. The work will be undertaken, in close collaboration with Dr R. R. Frost, in the Cryptogamic Botany Laboratories of the University. Appointment will be for one year from October 1 in the first instance, renewable for two further years. Salary £2,118 to £2,247 to £2,412 p.a. Particulars and application forms (returnable by July 1, 1974) from the Registrar, The University, Manchester M13 9PL. Quote ref: 110/74/N. (2411)

UNIVERSITY OF BRISTOL
ORGANIC GEOCHEMISTRY UNIT
POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Fellowship to work in collaboration with Professor G. Eglinton and Dr J. R. Maxwell on the lipid-type constituents of recently-deposited aquatic sediments and their contributing organisms, with a view to understanding the distributions which characterise these sediments, the contributions to different sediments and the reactions which alter organic compounds in the sedimentary environment. The research will involve the use of the Unit's computerised gas chromatograph-mass spectrometer system. Previous experience in gas chromatography and mass spectrometry would be useful, though not essential.

The appointment is for one year, and is available from a date to be arranged with the successful applicant, at a salary of £2,118 minimum.

Applications, giving details of age, qualifications and experience, together with the names of three referees, should be sent by July 20, 1974, to Professor G. Eglinton, Organic Geochemistry Unit, School of Chemistry, University of Bristol, Bristol BS8 1TS, from whom further particulars may be obtained. (2425)

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF BIOCHEMISTRY
RESEARCH STUDENTSHIP

Applications are invited for a Research Studentship available from October 1, 1974, in one of the following areas: structural studies on cytochrome oxidase; control of ketone body metabolism; effects of drugs and hormones on glyceride biosynthesis. Where appropriate, research will involve collaboration with clinicians.

Candidates should hold, or expect to graduate this summer with, a 1st or upper 2nd class Honours degree in an appropriate discipline.

Applications should be sent as soon as possible to Dr Dils, Department of Biochemistry, The Medical School, University of Nottingham, Nottingham NG7 2RD. For further details telephone 0602 56101, ext. 3229. (2410)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for the following:

RESEARCH SCHOOL OF CHEMISTRY

RESEARCH FELLOWS:

Appointments will be for two or three years beginning in 1975, and may be made in the following areas:

Organic Chemistry: (Professor A. J. Birch, Mr. R. W. Rickards, Dr. J. K. MacLeod): Structure determination and biosynthesis of natural products, including antibiotics and other biologically-active compounds, mould metabolites, and plant and marine products; insect chemistry; total synthesis involving new reactions, organic aspects of organometallic chemistry; mechanisms and results of metal-ammonia and related reductions.

Inorganic Chemistry: (Professor R. L. Martin, Dr. A. M. Sargeson, Dr. D. A. Buckingham, Dr. M. A. Bennett): Synthesis, structure, and reaction mechanisms of a wide range of transition metal complexes. Current interests involve substitution mechanisms at metal ion centres, reactions of coordinated ligands, strategy and stereospecificity in synthesis and quantitative conformational analysis. Interests in inorganic biochemistry include sulphur chelates, iron and ruthenium porphyrins iron transport chelates and the metal promoted synthesis and hydrolysis of small peptides and related substrates. Organometallic complexes, especially those of olefins, carbon monoxide tertiary phosphines and unstable organic molecules such as cyclic acetylenes. Electronic and magnetic properties of paramagnetic materials.

Physical and Theoretical Chemistry: (Professor D. P. Craig, Dr. J. Ferguson, Dr. R. Bramley): Electronic spectroscopy, especially of crystalline solids, U.V. spectroscopy and photochemistry especially of molecular crystals and small aggregates. Transition metal ion spectroscopy, ion pair interactions, exchange effects and magnetic circular dichroism. Intermolecular forces. Electronic properties of molecular crystals. Magnetic resonance spectroscopy, particularly EPR of photo-excited triplets in molecular crystals.

X-Ray Crystallography: (Dr. G. B. Robertson): Structural chemistry of organometallic, inorganic and biologically active organic molecules (with present emphasis on organometallics). Improved methods in X-ray diffraction analysis.

Mass Spectrometry: (Dr. J. K. MacLeod): Isotope labelling and metastable studies of specific fragmentation processes, combined g.c.-m.s. analyses of biological mixtures. Ion Cyclotron Resonance spectrometry involving studies of gas phase ion-molecule reactions to investigate their structures; reactivities and thermodynamic properties.

Analytical Chemistry: (Miss B. J. Stevenson): Micro and submicro metal and anion analyses. The School is non-departmental and is well equipped to contemporary standards, especially in optical, NMR and EPR spectroscopy, mass spectrometry, X-ray, crystallography and cryogenics. There are comprehensive workshop facilities. In computing there is access to the School PDP 11 and the University Univac 1108 systems.

There is no application form. Applicants for these posts should supply a curriculum vitae, list of publications, a statement of research interest, together with two passport-sized photographs and the names and addresses of three academic referees, to the Acting Academic Registrar, Australian National University, P.O. Box 4, Canberra, ACT 2600, Australia.

Closing Date: **15 July 1974.**

SALARIES: Salaries on appointment to the posts will be in accordance with qualifications and experience within the ranges: Research Fellow $A8696-$11901 p.a. Current exchange rates are approximately $A1 : 67NP : $US1.49.

OTHER CONDITIONS: Tenure: Research Fellow normally for three years in the first instance with the possibility of extension to a maximum of five years.

Reasonable travel expenses are paid and assistance with housing is provided for an appointee from outside Canberra. Superannuation (where applicable) is on the FSSU pattern with supplementary benefits.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants for the post in the Urban Research Unit should write to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF for further particulars before applying. (2445)

POSTDOCTORAL FELLOWSHIP IN MATHEMATICS/ECOLOGY

A Mathematician is required to assist in developing theoretical models of ecological systems and testing them against experimental data. No previous experience in biology is required. The fellowship will be tenable for one year and the initial salary will be £2,280. Enquiries should be addressed to: Dr P. T. Saunders, Department of Mathematics, Queen Elizabeth College (University of London), Campden Hill Road, Kensington, London W8 7AH. (2432)

THE UNIVERSITY OF THE WEST INDIES

TRINIDAD

Applications are invited for the post of RESEARCH FELLOW/JUNIOR RESEARCH FELLOW (ANIMAL NUTRITION CHEMIST), DEPARTMENT OF LIVESTOCK SCIENCE. Applicants should be graduates in Animal Science or Agricultural Science (with a major in Animal Science) with postgraduate qualifications in the nutrition of livestock; an interest in the nutrition of non-ruminant animals is desirable. Salary Scales: Research Fellow: TT$12,612-TT$20,316 p.a. Junior Research Fellow: TT$10,200-TT$11,232 p.a. (£1 sterling = TT$4.8). FSSU Unfurnished accommodation for a maximum of three years will be let by the University at 10% of salary thereafter 20% of salary is payable in lieu of housing. Family passages Triennial Study leave. Detailed applications (six copies) including a curriculum vitae, and naming three referees should be sent to the Secretary, University of the West Indies, St. Augustine, Trinidad. Further particulars for these posts will be sent to all applicants. (2417)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF GEOLOGY

Applications for a Research Fellowship are invited from candidates with interests in Carbonate Sedimentology and preferably also in Geochemistry and/or ultra-structures. Appointment to date from October 1, 1974.

Salary: £1,929 to £2,223 (under review) F.S.S.U.

Further particulars, including information about advanced research facilities, from Assistant Registrar (S), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (3 copies) with names of three referees should be submitted by July 15, 1974. Please quote reference: NXZ. (2406)

UNIVERSITY OF SUSSEX

SCHOOL OF BIOLOGICAL SCIENCES

BIOCHEMISTRY GROUP

RESEARCH STUDENTSHIP

Applications are invited for an **SRC postgraduate research studentship for studies on the mechanism of hormone action.** Investigations into protein hormone-membrane receptor interaction and adenylate cyclase involvement in hormonal control processes are contemplated.

Applicants are expected to have a first or upper second class honours degree in Biochemistry or a related field.

Applicants with brief Curriculum Vitae and names of two referees to Secretary of Science, Science Office (E), University of Sussex, Falmer, BRIGHTON BN1 9RH (2456)

UNIVERSITY OF ABERDEEN

DEPARTMENT OF ENGINEERING

S.R.C. RESEARCH STUDENTSHIPS

Applications are invited from graduates with good honours degrees in engineering, physics, mathematics or geology for a few Research Studentships. Research groups within the department include those relating to linear electric motors (Professor J. F. Eastham), electronics and control, electro-chemical forming of metal, engineering dynamics, fluid mechanics, geotechnics including ground anchors and mining subsidence and structures. Further particulars may be obtained from the Head of Department (Professor T. M. Charlton, Engineering Department, University of Aberdeen, Marischal College, Aberdeen AB9 1AS), and applications must be complete by mid-July. (2455)

LECTURES AND COURSES

KINGSTON POLYTECHNIC

Graduate Membership of the Royal Institute of Chemistry

A one-year full-time course with next intake in September 1974. Kingston Polytechnic acts on behalf of the R.I.C. as the administrative college for the Part II examination in the Group 10 region.

Enquiries are invited from suitably qualified candidates (Grad. R.I.C. Pt. I or B.Sc.).

MSc (CNAA) In Molecular Spectroscopy

A two-year part-time postgraduate course in chemical spectroscopy with next intake in September 1974.

First year: lectures, tutorials and practical work in the methods of molecular spectroscopy. Second year: computer work and a research project.

One whole day per week.

Further particulars from the Secretary, School of Chemical and Physical Sciences, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. (2359)

A BAT-SHEVA SEMINAR

on "The interaction of Art and Science"

will be held in JERUSALEM, NOVEMBER 3 to 14, 1974

Sponsored by the B. de Rothschild Foundation for the Advancement of Science in Israel

Lecturers: J. Benthall, V. Bonacic, A. A. Buzzatti-Traverso, H. W. Franke, G. Kepes, A. A. Moles, A. M. Noll, W. Sandberg, J. J. Sweeney, several local lecturers.

Topics: Interaction and trends in art and science; Computer in graphics and design; Trends in computer art (audio, visual, tactile); A new language in art; Applicability of theories to computer art; Computer as a creative partner; The sociology of science and art; Aesthetics of the urban environment and problems of civic art.

The seminar is intended for research workers and advanced students.

Early registration (by Sept. 30, 1974) is desirable; applicants will receive background and preparatory material.

Please write, with brief Curriculum Vitae, to: Dr. Vladimir Bonacic, Art and Science, Bezalel Academy of Arts and Design, 10 Sh. Hanagid St. Jerusalem, Israel.

Preliminary information

April 1974 (2440)

CHELSEA COLLEGE
UNIVERSITY OF LONDON
DEPARTMENT OF PHYSIOLOGY

POST-EXPERIENCE COURSE IN IMMUNOLOGY

Principal Lecturers: Profs. J. G. Feinberg and I. M. Roitt.

The course is designed for graduates and senior laboratory staff interested in acquiring a broad background in Immunology. It will be conducted on Monday evenings during the three terms of the 1974-75 academic year, beginning on October 7, 1974. A certificate of completion will be issued to students who elect to sit and successfully pass a final examination.

For further information and prospectus apply to The Secretary, Department of Physiology, Chelsea College, Manresa Road, London SW3 6LX. (2466)

GRANTS

THE ROYAL SOCIETY GOVERNMENT GRANT FOR SCIENTIFIC INVESTIGATIONS

Applications for grants from the second allotment of the Government Grant for Scientific Investigations for the year 1974 should be made as soon as possible on forms of application to be obtained from the Executive Secretary of the Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG. No application can be considered which is received later than July 31, 1974.

Applicants must be of British nationality, resident in Great Britain or Northern Ireland. Grants may be made for purposes in connexion with the promotion and support of research in pure science other than for personal maintenance or payment of stipends; for the assistance of scientific expeditions and collections; but not in aid of scientific publications. (2366)

THE NATIONAL KIDNEY RESEARCH FUND

invites applications for grants for renal research at units within the United Kingdom. Application forms are available from The Secretary, 184B Station Road, Harrow, Middlesex HA1 2RH (01-863 4460). Completed applications will be required by July 31, 1974. (2454)

FOR SALE AND WANTED

Always wanted:
BACK RUNS OF JOURNALS
IN SCIENCE AND THE HUMANITIES
WM. DAWSON & SONS LTD.
Back Issues Department,
Cannon House, Park Farm Road,
Folkestone, Kent, England.
Tel.: Folkestone 57421. (1)

MISCELLANEOUS

SCANNING ELECTRON MICROSCOPY

Complete service offered for examination of biological and fibrous materials, including specimen preparation and photography. For further information write Box No. 2441, Nature, T. G. Scott & Son Ltd., Clement's Inn, London WC2A 2ED. (2441)

MEETING

NUDE MICE—THEIR HUSBANDRY AND USE

An informal one-day meeting on the husbandry and use of the Nude mouse will be held at the Medical Research Council, Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, SM5 4EF (Tel: 01 643 8000) on Tuesday, July 16, 1974. Applications to attend this meeting (for which there will be no charge) are invited from interested research workers. Numbers will be restricted to a total of 40 people. Copies of the programme are available from Dr. M. Festing at the above address. (2368)

Vth International Biophysics Congress 1975

COPENHAGEN, AUGUST 4-9, 1975

The Vth International Biophysics Congress will be held in Copenhagen from August 4 to 9, 1975. The opening and closing plenary sessions will be concerned with:

1. Secretory epithelia and the active transport of ions;
2. Electrical and chemical excitation.

The scientific programme will also include symposia organised by the Union's Special and Affiliated Commissions on

3. The role of proteins in membranes;
4. Ionic channels, ionophores, and noise in membranes;
5. The dynamics of macromolecules;
6. Spectroscopic methods and biological structure;
7. Cell injury and repair processes;
8. Fundamental studies with light and other types of radiation;
9. The assembly and structure of membranes;
10. Bioenergetics;
11. Contractile systems;
12. Structural characteristics and rheology of biological membranes.

On two evenings there will be symposia in memory of Aharon Katchalsky. Contributed communications will be presented at Poster Sessions.

In connection with the Congress an exhibition of scientific instruments will be arranged. Interested manufacturers should apply to the Congress Secretariat.

Those wishing to attend the Congress should apply for pre-registration forms to:
Vth International Biophysics Congress
c/o DIS Congress Service
3 Knabrostraede
DK 1210 Copenhagen K
Denmark

The deadline for pre-registration is August 15, 1974. Since the number of hotel rooms available in Copenhagen is limited, late applicants may have to find their own accommodation.

The number of participants will be limited to 2,300 active participants, 200 students and 500 accompanying family members. Priority will be given to persons who have first sent in the pre-registration form and fee.

A SHARP IMAGE FREE OF DISTORTION

Zeiss pocket magnifiers come in three sizes:

Single lens × 6	£8.75
Single lens × 10	£8.75
Double lens × 3 × 6 (and thus × 9)	£11.50

Made by Carl Zeiss of West Germany, these invaluable magnifiers are used in science, industry, medicine, map-reading, philately, electronics, geology, nature study etc etc all over the world. Beautifully made and remarkable value.

Prices include VAT and postage.

Send cheque or PO, or ask for a leaflet, to Carl Zeiss (Oberkochen) Ltd Degenhardt House 31-36 Foley Street, London W1P 8AP 01-636 8050 (15 lines)

ZEISS POCKET MAGNIFIERS

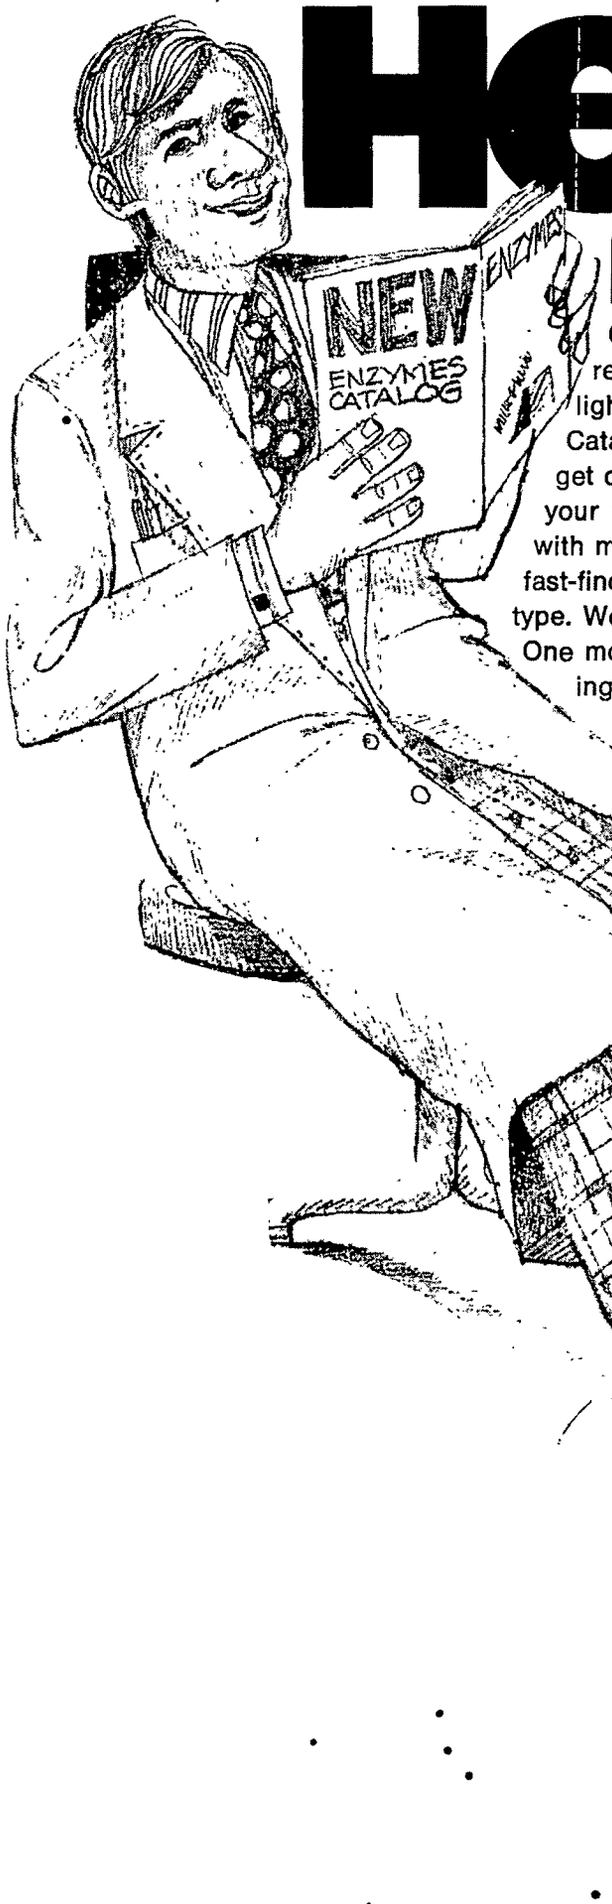
Research without the use of *LIVING* animals

Funds are urgently needed for equipping Tissue Culture laboratories and to sponsor scientists working on methods of orthodox medical research, especially Arthritis, without experimenting on living animals.

Further details on request.

Please send donations to:

The Dr. Hadwen Trust for Humane Research,
47 Whitehall, London SW1A 2BZ
Tel: 01-930 7698



Studies in History and Philosophy of Science

Studies in History and Philosophy of Science is a quarterly journal which analyses the genesis, evolution and logic of scientific thought. It attempts to unite historical and philosophical approaches to science

Recent papers include:
Maxwell's Methodology and his application of it to Electromagnetism, A. P. Chalmers. **The Astronomy of Eudoxus: Geometry or Physics?,** Larry Wright. **Conceptual Structures and Scientific Change,** Garry Gutting. **Whewell's Theory of Scientific Language,** Morton L. Schagrin. **Speculation in Physics:** The theory and practice of **Naturphilosophie,** Barry Gower **Feyerabend and Galileo: the interaction of theories, and the reinterpretation of experience,** Peter K. Machamer. Edited by Gerd Buchdahl, Reader in History and Philosophy of Science, University of Cambridge and Professor L. L. Laudan, Chairman, History and Philosophy of Science, University of Pittsburgh. Published by Macmillan Journals Limited.

Annual Subscription £8.50 (£9.50 U.S.A. and Canada). Prices applicable only to orders starting before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Heavy READING

Our 1974 Enzyme Catalog contains some pretty heavy reading—important reading. That's why we're making this lighthearted (but serious) offer to you: a new 1974 Enzyme Catalog. Great, you say, but what's in it for me? Lots. You get over 150 enzymes listed, both usual and unusual. To save your time, the brief, yet complete descriptions are included with method and units of assay and up-to-date references. The fast-finding groupings list enzymes both alphabetically and by type. We've lightened the burden of finding just what you want! One more thing: You'll be kept up-to-date on new enzyme listings as they are developed and made available. This service is provided on a periodic basis for all those on our mailing list. A request from you is all we need to make this offer complete. Call or write:

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.
- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.
- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

This is a new P.A.G.E.

Pharmacia Gel Electrophoresis System

for polyacrylamide gradient electrophoresis and other P.A.G.E. techniques

The complete system
Full capabilities for the new pore gradient electrophoresis technique, two dimensional studies, gel rod electrophoresis.

Polyacrylamide gradient gels PAA 4/30
Convenient ready-to-use gradient gel slabs give extreme resolution over the whole range 50,000—2 million MW. Self-limiting migration concentrates the zones after separation by molecular size.

Gel electrophoresis apparatus GE-4
4 gel slabs, 12 samples on each, or 16 gel rod capacity. Robust moulded construction with built-in cooling system. Full range of accessories for all applications.

Electrophoresis power supply EPS 500/400
Compact, all solid state. 0—400 mA constant current, 0—500 V constant voltage with automatic cross-over. Maximum effect 60 W. Full personnel and instrument protection. Available 1974.

Gel destainer GD-4
Electrophoretic or diffusion destaining of slabs or rods in a single operation. Twin cells. Active dye removal and solvent circulation. Results can be inspected at any time.

Destainer power supply DPS
Compact, reliable, all solid state. Push-button selected constant voltages 12, 24, or 36 V. Timer controls electrophoretic destaining up to 90 minutes.

Find out more about the Pharmacia Gel Electrophoresis System from your usual supplier of Sephadex® and Sepharose®.

Rising tide of energy nationalism

THIS issue of *Nature* is devoted largely to energy questions as seen by the scientist, from the whisky distillery in Scotland to the cattle dung plants of agricultural India. We cannot claim to be comprehensive in our coverage, but since it is not entirely unfashionable these days to devote large portions of journals to energy considerations it is unlikely that by half way through 1974 anyone who reads at all could claim that he lacked adequate briefing on almost any aspect of the energy situation. And yet it may be that although one can emerge convinced that there are large numbers of competent people in many countries exploring every avenue and leaving no stone unturned, there is still something naggingly wrong with the utterances of policy makers. "Self sufficiency by the 1980s", "indigenous resources", "national energy research strategies". Is not this talk the distant rumblings of a nationalism in science and technology that could make energy as isolated a field to work in as defence?

For some time, of course, marketing of energy has fostered nationalism through the possibilities of economic warfare, and the events of last winter must presumably be called an energy skirmish if nothing else. It is inevitable that countries which have traditionally disliked each other will now use energy as a weapon with no more hesitation than they have used blockades in the past. That is hardly a matter for debate. What is debatable is whether the remarkable nationalism that the energy crisis has engendered even amongst allies can do anything but harm to world order, and lead to tensions where previously there were none, and unnecessary duplication of activity where previously there was collaboration.

The disturbing thing for a scientist is not just that the possession of energy should be viewed in a national framework but that research itself into all aspects of energy should also be seen as too exclusively a national property. For instance, is it rational to talk of a programme to make the United States independent of the external world in energy matters when it shares thousands of miles of frontier, one common language and many similarities in life-style with Canada? Is the great nuclear reactor debate in Britain one which is too polarised into Britain against the United States. Is it further, one which should have been conducted at an international, or at least, a European level? If brain power as well as energy were regarded as a valuable resource the answer to all these questions would be yes. The giant oil companies have been an interesting example of supranational research and development; it would be unfortunate if with the decline in their influence this mode of operation were to be lost entirely, when it could with profit be used as a model for others.

If narrow interests restricted by geographical frontiers are to be overcome it is urgently necessary that international initiatives be pursued with great vigour. For this reason a proposal of Lord Robens on page 699 is worthy of attention. He suggests the formation of international energy research projects for such matters of common interest as solar energy. It is only around fairly specific objects that international research collaboration is likely to gel, and this as much as anything may be the reason the scientific community has been almost silent on the Kissinger initiative to internationalise energy concerns.

Solar energy would be an ideal project if only because of its world-wide applicability. As Dr Brinkworth points out on page 729, research and development in solar energy could also be seen as a means of giving aid to developing countries. What is more, the equipment need not be so complex that it is impossible to build and operate except in high technology societies. This too is a subtle consequence of too much national research policy; that the device only works when its maker is on hand and consequently it proves impossible to export. Further, if the work is removed to a government laboratory the economic need for an exportable product may be less to the fore and the formal obstacles to international collaboration much more extensive.

The dangers of nationalism in energy research are great. The antidote to them is not to be found in international committees of bureaucrats but in grass roots action by scientists themselves working across frontiers.

100 years ago

Proposed Issue of Daily Weather Charts of Europe and the North Atlantic

I HAVE the honour to inform you that Capt. Hoffmeyer, Director of the Royal Meteorological Institute of Copenhagen, has sent me a circular announcing his intention to publish daily charts of the weather for the district from 60° E. to 60° W. long. and from 30° to 75° N. lat. The charts for the three months—Dec. 1873-Feb. 1874—will be published as an experiment.

The cost will be four francs per month, exclusive of postal charges.

Capt. Hoffmeyer states that he can only deal with central offices, and has requested me to undertake these islands as regards the distribution of the charts. I have therefore to announce that I have been instructed by the committee to subscribe for twenty-five copies of these charts, and I shall be happy to supply copies for the three months to any gentleman, at the cost of 11*s*. to cover carriage from Copenhagen, and postage from London to his address. ROBERT H. SCOTT, *Director*

Meteorological Office, June 22

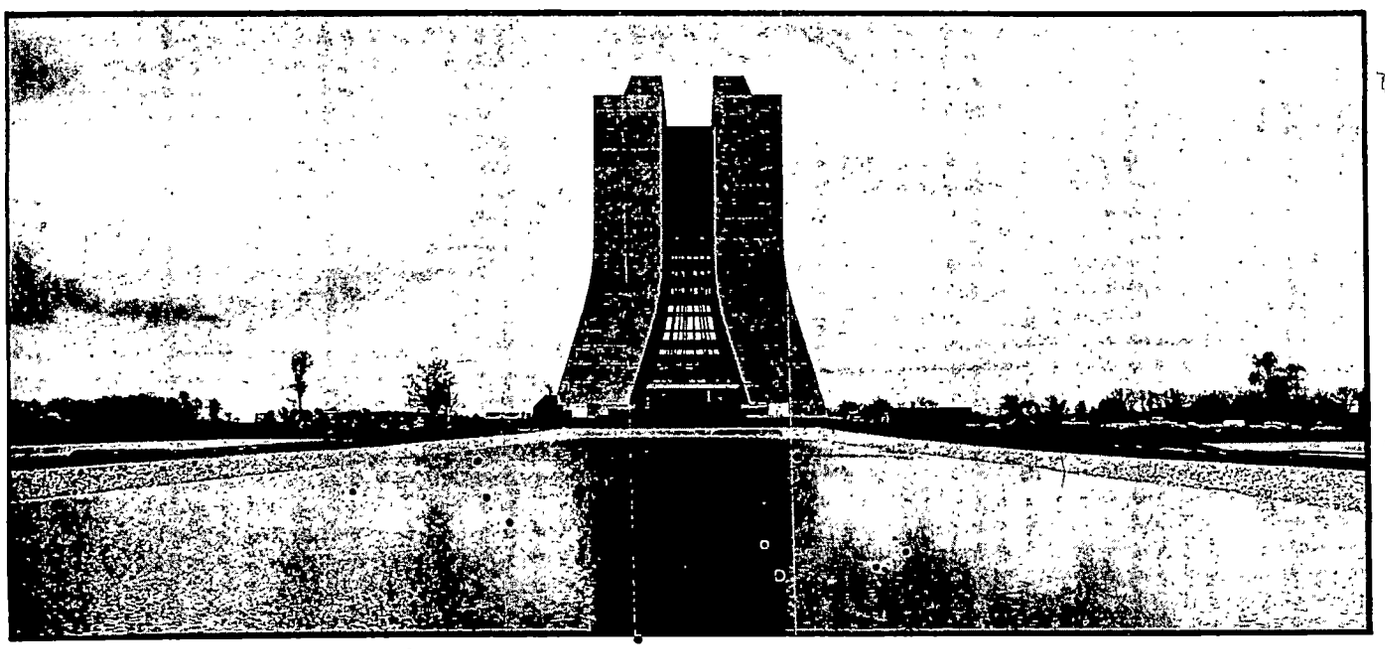
From *Nature*, **10**, 146, June 25, 1875.

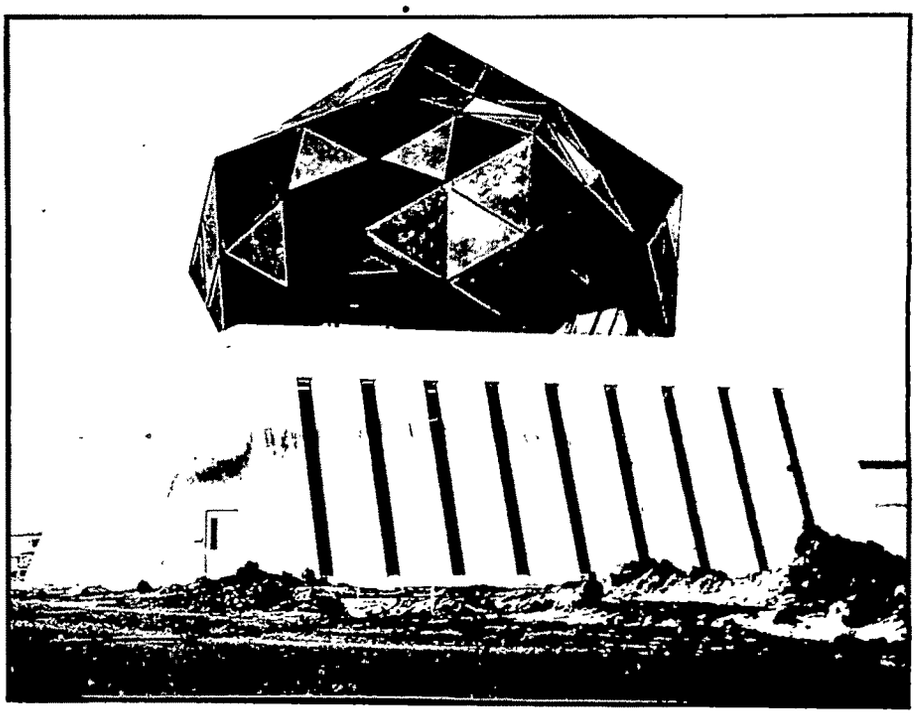
Sealing wax and string at $250 million

Miranda Robertson discusses the contribution that the Fermi National Accelerator Laboratory (pictured at bottom) is making to high energy physics.

THE dedication last month of the National Accelerator Laboratory (FNAL) to Enrico Fermi was a tribute to the man and an acknowledgement of the traditional link between the Chicago laboratory which saw the first nuclear chain reaction and the laboratory at Batavia, 35 miles west of Chicago, which now houses Fermi's original Chicago cyclotron (demoted to muon focussing) as well as the world's most powerful proton accelerator.

But historical links apart, the laboratory must stand as a monument to its director Robert Wilson, one of many ex-colleagues or students of Fermi now working at Batavia. When he agreed in 1967 to undertake the task of constructing the machine, Wilson brought to an already controversial project not only the experience he had gained in building the Cornell accelerator, but his own controversial approach—a latter-day, $250-million version of the sealing-wax-and-string tradition combined with a willingness to take a venture on the chance of greater dividends.





Robert Wilson: controversial

The commitment of funds to so expensive a project was a problem from the start. Wilson's achievement has been to do more than was planned with less than was hoped: to build a 500-GeV accelerator instead of a 200-GeV one with an initial commitment of $250 million instead of $350 million. A second source of early contention was the siting in America's middle West of what was to be an important international research centre. The geodesic dome of the bubble-chamber assembly building, the curved and corrugated roof of the meson area, and the main building with its trapezoid tower and ground floor forest are all part of a conscious attempt to mitigate the otherwise somewhat featureless Illinois landscape and avoid the standard laboratory concrete block.

Wilson's brave innovations have created problems of their own. One of the least of these is the leaky roof of the meson building, actually made of sections of sewer; what is adequate to contain sewage, it turns out, is not adequate to withstand wind and rain. More serious problems connected with the functioning of the machine itself are candidly documented by Wilson in a recent article (*Scient. Amer.*, **230**, 72; 1974) tracing the progress of the project from its inception until pretty well the moment that the article went to press, when the situation was still changing. At that time, infuriatingly for the scientific community, the proton beam was only operational for about half the time. Moreover, operation at more than 300 GeV threatened to become a source of grievance to the local community by causing a 1% voltage drop in the Commonwealth Edison power lines which feed the machine.

By the time of the dedication, however, the voltage drop had been reduced to within an acceptable 0.5% by means of further capacitors and the accelerator was running at 485 GeV. Better still, it is now operational most of the

The geodesic dome at FNAL: red, white and blue fibreglass panels containing 120,000 'beverage cans' donated by the public.

time and the beam intensity has shifted up from 6×10^{12} to 1×10^{13} protons per pulse close to the goal of 5×10^{13}.

Not that either the teething troubles of the laboratory or its tradition of bold innovation are now at an end. Within days of the dedication ceremony, a new transformer inexplicably failed, setting the machine back to an upper energy limit of 300 GeV for most of the summer. On the other hand, a project budgeted at between $4 million and $9 million is under way to test the feasibility of doubling the beam energy yet again. Wilson's path to the tera electron volt would be through superconducting magnets (more new technology), possibly housed within the existing tunnel (more penny saving). So far, because of the technical uncertainties, plans extend only as far as a protodoubler, to be inserted into a small section of the ring through which part of the beam could be run. Experience with the protodoubler should make it possible to gauge the problems of construction, refrigeration and installation of the superconducting magnets, as well as the possible damaging effects of radiation.

Superconducting magnets also enter into plans, still awaiting proton beams and one electron beam approval, for three intersecting storage rings to contain two, and known as POPAE: protons on protons and electrons. But meanwhile, important new phenomena in high energy physics are emerging at an alarming rate from other laboratories, in particular CERN in Geneva and SLAC at Stanford where the last year has seen the first evidence for a unified theory of the weak and electromagnetic interactions (*Nature*, **245**, 119; 1973), and the quark in a curiously paradoxical position—strongly supported by some recent results and equally seriously threatened by others. At this exciting and critical phase in fundamental particle research and with only two years to go before the new CERN accelerator achieves comparable energies, what has FNAL, as the principal sink for high energy funds in the United States, to offer?

The answer lies in the range of high energy secondary particles produced by the collision of the proton beam with its target. FNAL neutrinos and mesons come out at higher energies than those at CERN, and the Batavia synchrotron is the only source of really high energy muons, whose existence as a kind of massive electron is one of the outstanding puzzles of fundamental particle physics. Colliding beams, which have produced all the surprises, produce secondary particles of only relative low energy.

Many of the most recent results promise to support the efforts of theoretical physicists to find a unified explanation of the four physical forces, and to tie together within some fundamental relationship the embarrassing plethora of particles that comes hurtling out of the nucleus when it is hit with particles of energy more than a GeV or so. But some of the very latest threaten to leave them gasping. FNAL should be in a unique position to fill in the emerging picture in three areas.

The first is that opened up by CERN experiments with a neutrino beam on a stationary target of liquid freon in the giant bubble chamber Gargemelle, where the apparent observation of neutral currents represented evidence for the unity of the weak and the electromagnetic force, as proposed by Steven Weinberg and Abdus Salam. FNAL, with its much higher energy neutrino beam, has already corroborated the CERN result (*Nature*, **249**, 211; 1974) and should now be able to contribute a more quantitative understanding of the phenomenon.

Preliminary data should soon be available on a second question, raised this time by CERN's proton-proton colliding beams. Quite unexpectedly, the interaction probability (or cross section) of the protons, instead of remaining constant, turned out to increase with increasing energy. Investigations at FNAL with other kinds of strongly interacting particle, which seem to be subject to the same non linearity, will concentrate on the problematic transition energy between constant and rising cross section.

The third question is that of the structure of the hadron: are all the strongly interacting particles made up of combinations of two or three quarks, according to the theories independently developed by Zweig and Gell-Mann? Both the neutrino scattering experiments and the colliding beams of protons on protons say yes, they could be, although the existence of internal structure in the hadron has to be inferred from the distribution of the emerging particles: no force has yet succeeded in ejecting a quark from its nucleon. Both high energy neutrinos and muons are available at FNAL for probing the interstices of the proton in more detail than before, and at a time when experiments with colliding beams of electrons and positrons at SLAC have produced results which stretch quark theory to the limits of its plausibility. The simplest version of the theory (and the pursuit of simplicity is the vocation of the theoretical physicist) predicts a constant ratio of emerging hadrons to muons as collision energy rises. But the SLAC experiment revealed a hadron/muon ration that increased with energy with no sign of levelling off at the highest reached. Some increase can be accommodated in more complex versions of quark theory, but if the curve goes up any further it will leave even the most elaborate quarks behind.

FNAL should be able to provide the answers to some of the new questions posed by the current spate of exciting and baffling results, and take its place as a focus of scientific, rather than political or administrative, controversy.

Moscow seminar under attack

from Vera Rich

THE latest development in the preparations for the "underground" Moscow seminar on Collective Phenomena and the Applications of Physics to Other Fields of Science' scheduled for July 1–5, 1974, has been threats of prison and (or) exile for the 'host', physicist Aleksandr Voronel, and military conscription for a number of participants.

In a statement made by telephone and addressed to the sponsors of the Seminar, the American Academy of Physics, the Royal Society, the association of scientific workers of France, Italy, Germany and other countries, and to the International Society of Jurists, Voronel said that on the morning of June 8, he was "taken by force" by agents of the KGB (in civilian clothes) from near his home and conveyed to the 43rd department of the militia (civil police), where "two hours later, Lt. Col. Anfisov read out to me a warning in the name of the State Security organs", in terms of the decree of the Supreme Soviet of December 25, 1972. This decree has never been published, nor was the text of it shown to Voronel. The warning, however, consisted of the following three points: the seminar is a "provocative measure, pursuing anti-Soviet aims"; holding it will be "in violation of the order existing in the USSR"; and Voronel's actions in promoting the seminar will fall under statute 74 of the criminal code of the Russian Federative Republic: "incitement of national emnity".

This is the first time that so serious an accusation has been levelled at an individual scientist. Previous harassment of Jewish scientists dismissed from their posts as a result of applying to emigrate to Israel has either consisted of charges of "parasitism" (of not being gainfully employed) or else of offences not directly related to their predicament (as in the case of physicist Viktor Polskii, charged with a serious driving offence).

Although Voronel, as the 'host' for the seminar is obviously the prime target, he is not the only participant personally threatened. Three members of the organising committee: Viktor Brailovskii, Grigorii Rozenshtein and Dmitrii Ram, who are under 40 years of age (the upper limit of liability to conscription) and also two intending participants M. A. Mikulinskii and a certain Khaits (no forename available) have been ordered to report for military service. Although their failure to comply with the order renders them liable to criminal prosecution, the conscriptees (whose academic exemption is assumed to have lapsed when they lost their jobs) are, in the long-standing tradition of those wanted by the KGB or its Imperial predecessors, "hiding in the countryside" until July 1 when (if not apprehended in the meantime) they will return to Moscow for the meeting. Mrs Irina Brailovskaya (herself an intending participant) and Mrs Rozenshtein are being subjected, like Voronel himself, to close surveillance by the KGB, in the hope of discovering the whereabouts of the missing men.

Voronel: threatened

Last Thursday it was reported that another committee member, cybernetici**s**t Aleksandr Lunts, had been arrested. The Scientific Council of the Institute of Solid State Physics of the Soviet Academy of Sciences has officially censured the participation of Professor Venyamin Fain and Professor Yakov Yosilevskii for their membership of the Organising Committee. Yosilevskii, having already resigned from his post at the Institute, could not be threatened with dismissal; Fain, however, after refusing an order to withdraw from the seminar, was formally reprimanded, which is normally the first step to dismissal. In spite of this pressure campaign, which, following his release, Voronel, in a telephone call to a contact in Israel, described as "unprecedentedly rough treatment", the Committee and the participants from the Soviet Union are still prepared to go ahead.

This harassment of the scientists seems to indicate that the preliminary attacks on the seminar (see *Trud* and *Sovetskay Kultura* of May 17, 1974), which attempted to present it as a "provocational attitude" initiated by the University of Tel Aviv have had little impact, except, as Voronel wryly commented, to give it unhoped for publicity in the Soviet press. In fact, the whole concept of the seminar originated in Moscow, as an almost spontaneous by-product of the summary dismissal from their posts of Jewish scientists who wished to emigrate to Israel. In 1973, a number of scientists who had been sacked in this manner were prevented from presenting their papers at an International Physics Conference in Moscow, They succeeded, however, in making the fact known to the foreign

delegates, and an open invitation was issued to attend an unofficial session in Dr Voronel's apartment, to hear and discuss the banned papers. In all, some 40 delegates attended this meeting, sitting tightly packed upon the floor.

Since that time, the dismissed scientists, in order to foster and preserve some sort of scientific environment for themselves, have been holding regular Sunday seminars. Although representing a wide range of disciplines, from Cybernetics to Sinology, the meetings have, in fact, proved a fruitful source of discussion and interdisciplinary understanding (far more so, perhaps, than the official type of conference in the Soviet Union which, after one or two "plenary" sessions, normally fragments into a number of narrow working groups meeting simultaneously so that virtually no interdisciplinary exchange is possible).

Although a second seminar was later instituted, under the leadership of Dr Grigorii Rozenshtein, dealing with the life sciences (Voronel's original seminar contained a preponderance of mathematicians and physicists), the idea of interdisciplinary exchange has remained a cornerstone of the concept of these seminars. Accordingly, the International Seminar planned for July is not, therefore, in any way an outside interference in the activities of Soviet science. Rather is it an invitation from a group of dismissed scientists—who are, incidentally, only exercising the "freedom of speech" and "freedom of assembly" guaranteed to them by articles 125–127 of the Soviet Constitution of 1936—for their colleagues abroad to participate in a special 6-day session of the seminar. The three international secretaries of the meeting, Professor Edward Stern of the University of Washington, Dr Norman Chigier of the University of Sheffield, and Dr Raymond Orbach of the University of Tel Aviv are in no way the organisers—they are, as it were, the intermediaries between the would-be participants abroad and the committee in Moscow. Consequently, in spite of the fears expressed by certain scientists abroad for the safety of their Soviet colleagues, the international secretaries cannot take it upon themselves to cancel the seminar—only Voronel and his colleagues in Moscow could take such an action, and this they are resolutely opposed to doing.

In spite of the increasing pressure, which Voronel himself attributes to the "unfortunate" coincidence of the Nixon visit with the date of the seminar, which, he says, has given the authorities an added incentive and "justification" for taking the meeting as a provocation, at the time of going to press, plans are still going ahead. Certain counter measures to the Soviet pressure are in preparation—the submission of letters signed, respectively, by the international sponsors of the seminar and by leading physicists to Dr Philip Handler of the National Academy of Sciences of the USA and Professor W. K. H. Panofsky of the American Physical Society, urging that the bodies they represent should give appropriate consideration to the situation. A conference on high energy physics, to be held at Imperial College, London, at the same time as the seminar, will be asked to express its solidarity and sympathy. The possibility of formal telegrams to Mstislav V. Keldysh, President of the Soviet Academy of Science, has also been suggested.

Meanwhile, the submission of papers continues: some 120 having been submitted so far, more than 75 of which are from the United States, and including such names as R. A. Dwek (Oxford), D. W. Sciama (Oxford), George Wald (Harvard), John Ziman (Bristol), Sergio Ricossa (Turin), D. Bargeton (Paris) and Peter Hemmerich (Konstanz); the subjects cover a wide range from theoretical cybernetics to medicine, from cytology to the theory of education, and from Marxist sociology to theology.

The intending participants from abroad have made the necessary applications for their visas, and, at the time of going to press, are still awaiting an answer. In the meantime, scientists attending the "official" physics conference in the Soviet Union at the end of June have been invited to stay on for the seminar, as happened last year. In Moscow, the organising committee, under increasing pressure, continue their preparations, and, it is understood, have arranged for alternative venues, should Voronel's apartment become unavailable at the last minute. Although the final outcome remains uncertain, it is clear from the attitude of the organisers, both at home and abroad, that should the International Seminar fail to materialise, it will not be due to any slackening of efforts on their part.

Israelis hope for Mediterranean oil

Nechemia Meyers, Rehovot

DRILLINGS in the Mediterranean may soon bring the promise of oil self-sufficiency to Israel. Preliminary surveys of the sea bed off Israel's coastline—at the edge of, or just beyond, the continental shelf—have turned up geological structures which may yield oil, according to a statement made last week by the head of Israel's Oceanographic and Limnological Research Company, Yohai Ben-Nun. Ben-Nun, former OC of the Israeli Navy, was reporting on surveys made by his company in cooperation with the Marine Geology Unit of the Geological Institute.

Advanced seismic equipment has already been acquired, added the Admiral, for more exact investigation of these structures and for pinpointing possible drilling sites. While not guaranteeing that oil would be found, he described the anticlinal structures as "very promising indeed". Some of the sites are at depths that make exploitation difficult, given present-day technology, but new techniques being developed elsewhere in the world should make drilling economically and technologically feasible in a few years time.

Meanwhile, plans are going forward for drilling on the continental shelf and on the mainland. Dr Zvi Dinstein, who is in charge of Government oil operations, has announced that IL25 million (£2.5 million)—most of it private capital—will shortly be invested in probes along and just off the Coast Plain from Netanya to the Lebanese border. Surveys are also going on further to the south, particularly in the Gaza Strip area.

Considerable differences of opinion exist in regard to the possibility of striking oil around the Dead Sea. A group of foreign and local investors is reportedly willing to invest millions in drillings there, because, they believe, the asphalt found in the area indicates the likely presence of oil. Other observers—and geologists—think the asphalt only shows that oil was there, but that this oil has 'migrated' away.

Israel hoped that it had entered the oil era 20 years ago. For in September 1955, regular broadcasts were interrupted to announce that oil had been struck in the Lower Cretaceous sands at Heletz, 35 miles south of Tel Aviv and seven miles east of the Mediterranean coast. Special songs were composed in honour of the occasion and stocks of local oil companies shot sky-high. But production did not live up to expectations. In 1965, at its peak, Heletz and the surrounding fields yielded 202,000 tons of crude oil. Today production is only one-quarter of that figure.

The Six Day War brought Israel access to the Abu Rodeis oil fields in Sinai, which yielded 4.5 million tons in 1973, as against 5.3 million tons in 1972. A further pull back of Israeli forces could cut off that supply of oil altogether, a fact which lends special urgency to drillings in 'old Israel'.

Dear Russell . . . Dear Dixie . . .

by Colin Norman, Washington

A COUPLE of months ago, the Atomic Energy Commission (AEC) received a rude shock from a sister agency in the federal government when the Environmental Protection Agency published a blistering critique of some of the AEC's key justifications for pushing ahead at breakneck speed with the breeder reactor programme. EPA's temerity in questioning some of the arguments made in support of the most important energy research and development programme in the United States evidently hit a raw nerve in the AEC for it has prompted a frosty letter from AEC chairman Dixie Lee Ray to EPA administrator Russell E. Train, and a polite but equally frosty defence of EPA's actions in a reply from Train to Ray.

EPA's critique, which was published on May 4, tore to pieces many of the arguments put forward by AEC in a draft report on the environmental impact of the breeder reactor programme, and EPA gave the report the lowest possible rating of "inadequate". AEC was under court order to put the draft report into final form by June 14, but following EPA's criticisms, AEC sought and received an extension of the deadline. A final environmental impact statement is now expected sometime late in the summer or early autumn.

The dispute between the two agencies could later play an even more important part in the fierce battle now being waged over the breeder reactor, however, for EPA's criticisms may provide the basis for legal action to delay or block the programme by nuclear critics if AEC's final impact statement fails to respond adequately to the points raised by EPA.

But what seems to have offended AEC officials in particular is the manner in which the criticisms were delivered. According to Dixie Lee Ray's letter, the criticisms came as a shock because the two agencies had previously agreed to cooperate in preparing the draft environmental impact statement, and EPA officials had given "repeated telephonic assurances throughout (the) drafting period that there were no problems" with AEC's analyses. "We cannot understand the way in which EPA handled its recent comments" Ray said, and added that "surely there are more constructive ways of handling this and similar situations".

Train replied that although he shares Ray's concern that the two agencies should work constructively together, effective coordination in producing the statement proved to be impossible, and he said that when differences of opinion arise on impact statements, "our official comments must and will identify these issues and EPA's concerns". In other words Train made it perfectly clear that when his agency believes that another agency in the federal government has produced a poor environmental impact statement, EPA will continue to speak out.

Because of the importance of the fast breeder reactor programme—it is the largest single energy research and development programme in the United States and it will provide the keystone to the entire nuclear power programme in the 1990s and beyond—officials of the AEC, EPA and the White House Council on Environmental Quality met in September last year to try to ensure that the drafting stage of the impact statement would proceed as smoothly as possible. It was agreed at that meeting that AEC would provide EPA with draft copies of chapters of the statement as soon as they were written.

But, according to Train's letter, although AEC supplied EPA with material beginning in December last year, the three most controversial aspects of the statement—those dealing with plutonium toxicity, safety and cost-benefit analysis—were not completed until February. As far as the cost benefit material was concerned, EPA in fact received no draft at all. Thus EPA had little or no input into those parts of the statement, and as it turned out they were the most heavily criticised parts. Train also pointed out that in the September meeting last year EPA officials identified 14 topics which should be discussed in the impact statement, but only two were addressed in full and five were addressed in part.

Although AEC's pique and EPA's defence of its actions represent little more on the surface than a bureaucratic squabble, they do underline a couple of important points. The first is that with the White House beleaguered by calls for President Nixon's impeachment and resignation, federal agencies are taking an idependent line on many issues which would normally be under tight White House control—the EPA, for example, has been taking a stand against several administration policies and several top administration officials have even said in public that they have no fear of White House pressures any more. And the second point is that EPA's independent stand on the breeder reactor statement, which would have been much more difficult in pre-Watergate days, is a vital part of the procedure laid down by the National Environmental Policy Act for ensuring that environmental concerns are taken fully into account in decisions made by the federal government.

Test ban soon?

MR BREZHNEV has now indicated that the Soviet Union is prepared to discuss a ban on underground nuclear weapons tests when Mr Nixon visits Moscow in late June. This together with the continued interest in Washington makes some sort of agreement, even if only an agreement to agree, a near certainty this summer. A treaty is likely to take the form of a threshold agreement in which tests are forbidden only if they produce a seismic signal larger than a specified value. This concept has been strongly criticised in recent weeks; the sort of value being talked about would permit explosions of up to fifty kilotons to be fired if appropriately muffled. A large majority of all tests fired at present are below that level of yield, so the threat to a weapons programme of a threshold treaty could be modest. The speech of Mr Brezhnev does however mention the question of a timetable for phasing out weapons tests entirely, an idea that will be much more difficult to sell to the United States. It will be interesting to see whether the Soviet Union insists on such an addition to any treaty that is signed, as it is potentially embarrassing to the United States and could endanger the talks.

Nuclear safeguards

STUNG by a series of public criticisms of the adequacy of its safeguards against the theft of nuclear materials, the Atomic Energy Commission has elevated nuclear security to a higher position in its bureaucratic hierarchy. The move is, however, unlikely to satisfy the AEC's critics in Congress who are pushing ahead with a bill to force the commission to pay much more attention to nuclear safeguards than it has in the past.

The move consists of amalgamating the present Division of Nuclear Security and the Division of Nuclear Materials Security into a single entity whose job will be to prevent the theft of weapons-grade plutonium and enriched uranium from AEC facilities and in transportation. Critics have long argued that responsibilities for preventing nuclear theft have been fragmented, and so the reorganisation at least helps to answer some of the complaints.

But it falls far short of recommendations contained in two recent studies of the AEC's safeguard regulations, and it also addresses only part of the safeguard problem, for the new division will be responsible only for

Anti-revisionism hits Scientia Sinica

THE attacks on Lin Piao and Confucianism in China which began in August 1973 have now spilled over into the pages of *Scientia Sinica*, the distinguished English-language journal of Chinese science published in Peking. In the most recent issue (Vol. 17, No. 2) alongside papers on a Markov description of stationary turbulence, graptoloidea and graptodendroids and pathogens of rice black streak dwarf disease is a section entitled 'Criticising Lin Piao and Confucius; combating and preventing revisionism'. Three testimonies are presented of the absurdity of Confucius' saying 'only the highest who are wise, and the lowest, who are stupid, cannot be changed'. Lin Piao, at one time Mao's Defence Minister and widely believed to have been killed in a plane crash in Mongolia in September 1971 whilst attempting to flee to the Soviet Union, is accused of following Confucius and 'twaddling that knowledge was endowed by nature' and 'slandering the working people as philistines . . . only caring for oil, salt, sauce, vinegar and firewood'.

"Many hands make mercury vapour light work . . ."

The first paper, uncompromisingly entitled '"The Lowest, who are stupid" are the wisest while "The Highest, who are wise" are the most stupid' is by Tsai Tzu-chuan of the Laboratory for Electric Light Source, Shanghai. He was exercised in the early 1960s by the imperialists who gloated over the Chinese incapacity to make a high-pressure mercury vapour lamp. However his group started from scratch and within half-a-year had delivered the goods. This success greatly heightened the morale of the proletariat and smashed the imperialist slander against China: 'advanced architecture but backward lighting'—which, it must be admitted, isn't heard too often these days. One in the eye for Lin Piao who wanted to restore capitalism by subjugating the working class to his fascist rule. As Chairman Mao put it 'Lifting a rock only to drop it on one's own feet is the behaviour of a reactionary fool'.

Next Yao Shih-chang of the Tuanchieh Production Brigade, Shantung, relates how Mao's saying that 'correct ideas come from the struggle for production, the class struggle and scientific experiment' is illustrated by his quest for growth of the peanut. His first attempt to raise the yield of his own village's crop of peanuts by importing the methods of a neighbouring village actually decreased the yield and he 'got snubbed'. Next year however he studied the cycle of growth more closely—'I was, so to speak, living together with the peanuts'. Eventually by removing earth round the basal parts of peanut plants he found he could raise the yield 25%. This he concludes is the result of not fearing hardships, being bold to practise and ready to get to the bottom of the matter. Lin Piao would not have encouraged this as he thought that the working classes cared only about money, and would have restored landlords. But now millions are clapping hands for joy, so 'let the reactionaries at home and abroad bark what they like.' Finally, Chao Pu-hü, a 'worker-peasant-soldier student' at Kirin Medical College describes his transformation from 'half-baked medical orderly' to 'people's medical officer'. He worked in a deaf-mute clinic and was intrigued by the failure of acupuncture in this field. The books said that there were forbidden zones, and that needles should only be inserted a restricted amount. Chao Pu-hü perceived this as akin to the 'idealist apriorism of Liu Shao-chi, Lin Piao and other swindlers' and proceeded to experiment on himself with prodigious lengths of insertion. This warmed his throat up so he applied the same to a girl Wang Ya-chiu. Three days of the treatment and she called out, for the first time in her life, 'Long live Chairman Mao!' Thus emboldened, he and his colleagues have cured more than 3,000 deaf-mutes in the last five years.

His last colourful words are—'Now those who had tried to check the advance of history as mantis shanks would a carriage were ground to pieces by the wheel of history, yet their reactionary ideology still stinks. We will thoroughly criticise their reactionary world outlook and carry the socialist revolution in the realm of the superstructure through to the end!' And so, on the next page, to a homogeneous denumerable Markov process.

nuclear material contained in AEC facilities, while the AEC's Regulatory division will retain responsibility for safeguarding nuclear material held by the nuclear power industry.

The reorganisation is thus unlikely to disrupt a move, spearheaded by Senator Abraham Ribicoff, to place nuclear security on the same bureaucratic level as the safety of nuclear power plants and to force increased security within the nuclear industry. The move, in the shape of an amendment to a bill designed to split up the AEC into a Nuclear Safety and Licensing Commission and an Energy Research and Development Administration, would create a top-level bureau concerned solely with nuclear safeguards. The bill has now been passed by the Senate Government Operations Committee and it is awaiting full Senate action.

Nature conservation

THE Nature Conservancy Council, having devoted the first months of its existence to internal reorganisation and the task of disentangling itself from the arms of the Natural Environment Research Council, is now ready to turn its attentions outwards again.

At a meeting in London recently, the Director, Mr R. E. Boote, outlined the aims of the 'new' Nature Conservancy. According to the Nature Conservancy Council Act of 1973 the NCC is now required to provide advice to the government on the development and implementation of all policies for or affecting nature conservation in Great Britain. This has enormous implications for the NCC which they intend to take very seriously, now that they are an independent body.

Mr Boote promised that they would not hesitate to make public advice given to the government and disregarded when they felt that circumstances warranted such disclosure.

The NCC continues to manage the 300,000 acres of nature reserves under its control but has relinquished its research stations to NERC. The NCC now commissions the necessary research, mainly from NERC, on the Rothschild customer/contractor principle. When asked whether conflict might arise between the research carried out for the government for NERC and that commissioned by the NCC, Mr Boote replied that as they had complete control over the commissioning of their own research they could always go elsewhere. The NCC is at present financed by a parliamentary grant which this year has been "sufficient".

correspondence

Earth scientists

SIR,—Sir Peter Kent, Sir Kingsley Dunham and Professor Percival Allen charge (*Nature*, June 14) that my article of April 26 was "erroneous and misleading" and "appeared in *Nature* without an attempt to check the facts". They are quite wrong; indeed in their letter they commit the very sins of which they choose to accuse me, not the least of which is to put into quotation marks an inaccurate version of a phrase I actually wrote.

In my original article I claimed that the General Secretary of the European Geophysical Society (EGS) discovered the planning of the Reading meeting of European geological societies "more or less accidentally"—a claim that Sir Peter and his colleagues attempt to refute by pointing out that the EGS General Secretary was specially informed of the meeting by its organisers. Indeed he was; but the fact is that the meeting had first come to his attention (more or less accidentally, as I said) more than two months before the 'official' information was received. Sir Peter and his cosignatories also point out that the EGS President was sent a "special letter" inviting EGS members to participate in the Reading meeting and soliciting topics for discussion. A letter was indeed sent, although in view of the fact that it bears a remarkable resemblance to other letters sent elsewhere, its "special" nature may be doubted.

The most significant aspect of the letter to the EGS President, however, is that the contents of the letter are precisely as Sir Peter and his colleagues describe them—which suggests that the basic point of my article has been missed. No one has suggested that EGS members have not been invited to, or would not be welcome at, the Reading meeting. But what is being suggested is that the organisers of the Reading committee have gone ahead with the first stage of what may well develop into a Geological Society of Europe (GSE) without first consulting the governing bodies of the European earth science societies already in existence, most notably the Council of the EGS.

Sir Peter and his colleagues presumably felt that such consultation was unnecessary. Others, including myself, disagree. For reasons which are too complex to go into here, in both Britain and the United States (and possibly in other countries too) geologists and geophysicists have come to be associated with different organisations. It is perhaps now too late to change that situation; but in my view it would be a tragedy if a similar sort of separation were to be perpetuated on a European-wide basis. This does not necessarily imply the need for an all-embracing European Earth Science Society, for, as I pointed out in my original article, the problems involved in running such a Society would be almost insurmountable. But what it does mean is the need for close coordination. Geologists may deplore it, but in view of the fact that the EGS already exists the onus must be on anyone thinking, however remotely, about a GSE, to take special care to avoid harmful separation. In return, I feel sure that existing organisations will see the need to modify their own programmes accordingly. In any event, true coordination is much more than simply sending letters announcing a conference.

Sincerely yours,

PETER J. SMITH

Kidney transplants

SIR,—The article "Transplantation: the failing machinery", (*Nature*, April 19, 1974) I thought, represented the kidney donor problem in this country very accurately and unfortunately its comments were confirmed by Dr Dudley's letter (May 31). He was quite right that in the north-west area of London there are no neurosurgical centres, but for years the Atkinson Morley Hospital in the south-west has been the source of many kidneys going to St Mary's. It should be pointed out that head injuries form only a small proportion of the potential donors. In the south-east only 20% of all kidneys come from patients dying from trauma and less than 5% from a recognised neurosurgical unit. The majority of our donors come from general hospitals and they are by no means always on a ventilator. Indeed, in September, 1973 there was a suitable donor at St Mary's Hospital, Harrow Road, which was turned down by their Transplant Unit. This year there was a similar case at St Charles Hospital, W10. These kidneys were in fact taken by clinicians from the London Transplant Group and used in the national pool. It cannot be argued that kidneys from these donors were unsuitable for transplantation. In fact I have sent similar kidneys to St Mary's Hospital and the national pool with good results. Eighty per cent of all kidneys taken in south-east London are from similar donors (60% are not on a ventilator) and 50% function immediately.

As far as potential donors suffering from primary cerebral tumours are concerned, and the fact that they go elsewhere for terminal care, is no reason why those kidneys should be lost to the transplant pool. In Newcastle, all similar patients are put on a donor register and whichever hospital is concerned with their terminal events notifies the transplant team before death.

From my own experience of working in the Casualty Department at St Mary's, Harrow Road, and from conversations with nurses, housemen and students, it is fairly obvious that there is suitable donor material not being collected in at least one of the hospitals in the north-west area of London. I think that this represents "unequivocal evidence" that there is a lack of understanding and cooperation between doctors which is responsible for the lack of kidneys available for transplantation today.

Yours faithfully,

M. BEWICK

Department of Surgery,
Guy's Hospital, London SE1 9RT

SIR,—May I make a few comments on Mr H. A. F. Dudley's criticisms (May 31) of my article on kidney transplants (April 19)?

The figures for the numbers of kidneys received from and contributed to the central pool came from the DHSS Organ Matching Service at Bristol. And having spoken to a number of doctors and surgeons, I was convinced that there was, in some cases, more take than give—and not necessarily because of any variation in the number of cranial trauma patients.

The lack of cooperation between doctors was one of the reasons given by the Royal College of Physicians for the lack of kidneys. I also spoke to a considerable number of hospitals and doctors and found in many cases complete ignorance about the transplant programme and about transplant procedures regarding donor kidneys. And if Mr Dudley wants "unequivocal evidence" surely Mr Barnes' story is it.

Yours faithfully,

ROBIN LAURANCE

Riverwoods, Marlow, Bucks SL7 1QY

Collaboration fixes unique QSO spectra

IN these days of proliferating publications, the article which appears on page 743 of this issue of *Nature* is worthy of more than just passing attention. The paper itself is of great significance to astronomers, since it provides some of the first indications of the radio spectra of the QSOs OH471 and OQ172. These are the only radio sources yet definitely identified with optical objects which have redshifts greater than $z=3$, and as such they are, on the cosmological interpretation of those redshifts, the two most distant objects known to man.

The very high redshifts also affect the radio spectra, of course, although the absence of features comparable to the lines in optical spectra makes it impossible to measure the redshift of any QSO by radio observations alone. But in effect by shifting the radio spectra the redshift brings new regions into the band of frequencies which can be covered by radio telescopes based on Earth. Perhaps some of the features seen in these spectra are, then, typical of features which would be discovered at rather shorter wavelengths in the spectra of QSOs with smaller redshifts.

In the excitement caused by the identification of these objects, it would surely have been natural to expect everybody with access to a radiotelescope to make observations and rush them into print. The result would undoubtedly have been a scattering of reports in various journals, causing much adrenalin to be produced by other frustrated radio astronomers desperately trying to keep up with 'the literature' and to find some overall picture of the radio spectra of the two QSOs.

But in fact a different approach has been adopted. Contributions which might have formed the basis of ten separate short notes here, there and everywhere have been combined in the one article we are publishing today. The degree of international cooperation involved is notable even for astronomy; as a result this paper provides in one place just about all that needs to be said (at this stage) about the radio spectra of OH471 and OQ172. *Nature* is always happy to cooperate in ventures like this which both reduce the number of separate papers we have waiting to be published and, we hope, provide a service to the scientific community (see, for example, the Cygnus X-3 issue of *Nature Physical Science*, **239**, 113–136; 1972).

JOHN GRIBBIN

Origin of plasmocytoma cells

THE DNA polymerase activity known as terminal deoxynucleotidyl transferase has been reported in murine plasmocytoma cells, with interesting implications for the study if tissue differentiation (see page 775 of this issue of *Nature*).

Terminal deoxynucleotidyl transferase differs from the other known DNA polymerase activities in mammalian cells in that it catalyses the addition of deoxyribonucleotides to the 3′-OH end of preformed polynucleotide chains in the absence of a DNA template. Although this effect has been useful as a model for the mechanism of polymerisation (*Proc. natn. Acad. Sci. U.S.A.*, **65**, 1041–1048; 1971) and for end group labelling of deoxyoligonucleotides (*Eur. J. Biochem.*, **22**, 271–276; 1971), the biological function of the enzyme is unclear, and it has been suggested that it is a degradation product of DNA polymerase. But its role as a marker for the origin and state of differentiation of certain cells is an interesting possibility.

The terminal transferase activity was first isolated in calf thymus, and has since been demonstrated in the thymus of numerous animals, but in no other tissue. Thus the activity seems to be entirely tissue specific, and also shows a development cycle which arises early in the process of embryonic development and persists in the thymus of young and adolescent animals.

McCaffrey *et al.* (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 521–515; 1973) have found that cells from a patient with childhood acute lymphoblastic leukaemia (ALL) contain an enzyme with the properties of terminal transerase; this suggests that these tumour cells are thymic cells blocked very early in differentiation. Furthermore, the ALL cells lacked detectable surface immunoglobulin, a chacteristic of thymocytes. No activity was found in normal T-cells (thymus-derived lymphocytes), nor in three cultured human cell lines. This suggests that the enzyme was a marker for true thymocytes and provides hopes that an assay of this DNA polymerase might provide a diagnostic marker for whether a given leukaemia is of thymus or bone-marrow (bursal) origin.

Now Penit, Paraf and Chapeville have found that terminal transferase exists in murine plasmocytoma cells. This finding is surprising since these tissue-cultured cells have been thought of as B-cells (they express the immunological properties of cells derived from bone marrow). If the presence of terminal transferase activity in a cell is truly indicative of a thymic origin, then it would not be unreasonable to suggest that plasmocytoma cells represent an intermediate stage of differentiation between B and T cells. As Penit *et al.* point out, this has a precedent in a cloned line of thymoma (thymic tumour) cells produced by irradiation in mice. The thymoma cells possessed the T-cell characteristics of θ-antigen and anatomically thymic origin, and the B-cell characteristics of readily detectable surface immunoglobulin and immune complex receptor activity.

Unfortunately it is not yet possible to be certain that the expression of terminal transferase is evidence of an intermediate state of differentiation in plasmocytoma cells since immunological data are lacking, especially with regard to thymus antigens. A synthesis of immunological and biochemical approaches may elucidate the origin of cells containing terminal transferase activity and determine whether this will have diagnostic uses.

TONY PAWSON

Minor tyrosine genes of major importance

THE structure and function of transfer RNA are so well understood that it is surprising how little is known of the transcription of this RNA and of the genes from which it is transcribed. This is partly due to the difficulties involved in isolating the tRNA genes which are scattered through the genome in small clusters.

Unless the tDNA is chemically synthesised, it is only possible to obtain DNA enriched in tDNA genes, rather than pure tDNA. For example, using the DNA of a species of mycoplasma enriched so that the tDNA is 10% of the total, it has been possible to show that uridine is converted to pseudouridine post-transcriptionally. Forming hybrids between total cell DNA and tRNA has given some information about the size of the genes and supports the idea that the genes for tRNA are grouped together in twos or threes. But by far the most informative method has made use of the transducing bacteriophage φ80. This phase has an attachment site (in *Escherichia coli*) near the two minor tyrosine genes which together contribute 30% of the total tyrosine tRNA. The two genes are indistinguishable except in su^+_{III} cells where one of them—the suppressor gene—has a single base change in the anticodon region, which allows tyrosine to be read instead of the terminator codon UAG.

When the phage carrying one or other of the two minor tyrosine tRNA genes is transduced into *E. coli*, large amounts of tyr tRNA can be detected in the post-infection phase. In mutants in which this amount of RNA is reduced, it was found that this was because the processing of the RNA was less efficient, leading to an accumulation of the first transcription product. Using φ80 carrying one of the minor *tyr* tRNA genes (the suppressor mutant), the accumulated RNA was examined by Altman and was shown to contain some 40 nucleotides more than the mature tyr tRNA (*Nature new Biol.*, **229**, 19; 1971). Subsequent sequencing of the molecule by Altman and Smith (*Nature new Biol.*, **233**, 35; 1971) revealed several interesting features of this tyr tRNA precursor. It seems that, like the mature tRNA, the precursor also has a 'clover-leaf' secondary structure but differs from it in that bases modified on the active tRNA are unmodified in the precursor. The authors also present evidence that mutations which alter the amount of mature RNA produced are close to the point at which the precursor molecule is cleaved.

Chysen and Celis have used one of these mutations—one which reduces the rate of synthesis of su^+_{III} tyr tRNA—to determine whether the two minor *tyr* tRNA genes are transcribed into one large precursor or two separate ones (their results are described in *Nature*, **249**, 418; 1974). In this case it was necessary to infect *E. coli* with a transducing phage carrying both su^+_{III} and wild type *tyr* genes. They reasoned that if the two genes are jointly transcribed then a mutation which affects the rate of transcription of the su^+_{III} gene should also affect the rate of transcription of the wild type gene.

The experimental approach made use of the separation of tyrosine tRNA from bulk tRNA obtained by polyacrylamide gel electrophoresis. Once eluted from the gel the ^{32}P-labelled tyrosine tRNA was subjected to RNase T_1 digestion. Characteristic T_1 fragments identified tyr_{II} tRNA (the major species) and the two minor species tyr_I su^+_{III} and tyr_I wild type. By comparing the relative amounts of tyr tRNA I and II mutations which reduced the amount of tyr_I tRNA were identified, and those which reduced the level of su^+_{III} tRNA also reduced the level of wild-type tRNA. It seems therefore that the two genes are transscribed into one single precursor tRNA. Confirmatory evidence of this was obtained from an analysis of the RNA synthesised, after infection with φ80 carrying both minor *tyr* genes in cells deficient in RNase P (RNase P is the enzyme which cleaves the precursor to form the mature tRNA). The bands obtained by electrophoresis of the RNA were eluted and digested with RNase T_1. Of the fingerprints obtained there was none characteristic for a 'singlet' precursor of the wild-type tRNA.

Knowing that the two minor tyrosine tRNAs are transcribed together, it becomes particularly interesting to have some information concerning the structure of the genes. This is provided in an article in page 738 of this issue of *Nature* by Landy, Foeller and Ross, although at the time of writing the existence of the 'doublet' precursor was not fully established. Their approach was to compare the DNase digestion pattern of phage φ80 (parental) with φ80 su^+_{III} (singlet—the suppressor gene) and with φ80 su^+_{III} (doublet—the suppressor gene and the wild type). Limited digestion with site-specific nuclease endo R. *Hin*d, followed by electrophesis under different conditions, led to complete resolution of all the fragments. Most of the fragments were the same for all three RNAs of course, but three fragments were unique to the parental φ80; one fragment was unique to the singlet, one to the doublet, and five fragments were found in both singlet and doublet but not in the parental phage. These last fragments did not form hybrids with mature tyr tRNA and so their transcript may be that part of the precursor which is cleaved during tRNA biosynthesis. It seems that the size of one tRNA gene plus any unduplicated intergenic sequence is approximately 200-260 base pairs—about two or three times the size of tyr tRNA. The authors suggest a maximum of 125 base pairs for the intergenic sequence between the duplicated genes. Further sequencing of the DNase fragments will allow these figures to be more accurately assigned and provide a complete analysis of the *tyr* tRNA gene(s).

PAMELA HAMLYN

Alpine tundra change after road building

from Peter D. Moore
Plant Ecology Correspondent

ALPINE tundra habitats are simple in structure, yet often diverse in species. The species which can survive under such rigorous climatic conditions are of considerable biological interest because of their elaborate phenological and physiological adaptations (see Billings and Mooney, *Biol. Rev.*, **43**, 481; 1968). Their extreme adaptation to climatic stress may render them particularly susceptible to hardships of other kinds, such as human interference. A short growing season results in low productivity and this means that recovery following disturbance is bound to be slow.

Bell and Bliss (*Biol. Conserv.*, **5**, 25; 1973) studied regeneration of vegetation on areas laid bare by road construction in Olympic National Park, Washington, and found that after more than 30 years plant cover was still very low. Greller (*ibid.*, **6**, 84; 1974) has now produced similar data from Rocky Mountain National Park, Colorado. In this park two roads provide easy access to an open expanse of alpine tundra; one of the roads was constructed in 1920 and the other in 1932, but recolonisation of the verges, laid bare by construction activities, has been very slow.

Greller found that north-facing slopes had become dominated by *Poa fendleriana*, and south-facing slopes by *Agropyron scribneri*, both of which are tussock-grass species, well adapted to growth on unstable soils. It is a matter for concern that these slope communities are low in diversity and lack many of the more interesting

species of the tundra vegetation, but Greller's conclusion that succession plays only a minor part in these situations cannot be justified from his data. Fifty years is a relatively short time in the history of most successions and under the extreme climatic stress of alpine habitats one might expect even slower developmental rates. The current lack of vegetation can hardly be construed as proving a lack of successional development. Natural periglacial soil processes must surely act in an equivalent fashion to produce similarly denuded slopes.

Greller's suggestion that succession may be curtailed by soil dryness on the artificially steepened slopes of the banks is not likely to be correct. Many alpine species have xeromorphic adaptations, and Teeri (*Science*, **179**, 496; 1973) has found that *Saxifraga oppositifolia* can withstand water deficits as great as −55 bar. Drought is unlikely to prove a serious hindrance to the growth of alpine communities. Soil instability may slow down or even divert the course of succession, but one cannot assume that this is the case after only 50 years.

Nevertheless, one is faced with the fact that habitat disturbance caused by road building leaves scars upon the tundra landscape which may take many generations to heal and which, indeed, may never heal at all. This consideration should occupy a position of importance in the minds of those responsible for the routing of such highways. An additional problem is that of trampling pressures by those who gain access to the tundra along the highways. Alpine vegetation is particularly susceptible to this additional stress, as has been demonstrated in the Cairngorm mountains of Scotland, where the provision of easy access to the public (by roads and a ski lift) has led to ever-widening paths and trampled soils (see Watson in, *The Biotic Effects of Public Pressures on the Environment*, edit. by E. Duffey, Natural Environment Research Council, London; 1967). It may be that the instability of roadside slopes in the tundra areas of Rocky Mountains National Park will be one of the least concerns of its conservators.

Blastokinin induction by steroids

from our Steroid Biochemistry Correspondent

SINCE the identification in rabbit uterine fluid of a specific protein blastokinin or uteroglobin, much research has been carried out to define the precise physiological role of this compound. It appears in uterine fluid after ovulation and its concentration is high at the time of implantation. One of the effects of the protein is to stimulate the transition of the morula to the blastocyst, a transition, however, which will also occur *in vitro* without blastokinin provided some other protein which will bind progesterone is present. Addition of progesterone to culture media containing blastokinin stimulates RNA and protein synthesis by the embryo and blastokinin may function as a binding protein for steroids which may be needed by the embryo. Blastokinin will not only bind progesterone but also seems to be controlled by progesterone.

The control of this protein by progesterone and related compounds has been investigated by Arthur and Chang (*Fert. Steril.*, **25**, 217–221; 1974). Steroids were administered to rabbits daily for 5 d post-oestrus; 24 h later the animals were killed and the uterine fluid was examined by Sephadex column chromatography for the presence of blastokinin. The protein was detected in rabbits treated with progesterone and the 17α-acetoxyprogestogens, chlormadinone acetate and medroxyprogesterone acetate. The amount of blastokinin in uterine fluid was similar after treatment for 5 d with these steroids to that found on the fifth day of pregnancy. These progestogens are known to have a spectrum of biological activity similar to progesterone whereas the other group of orally active progestational compounds related to 19-nortestosterone have a different spectrum of activity; these latter compounds, as well as oestrogens, were ineffective in inducing blastokinin.

The relation between steroid structure and blastokinin induction merits further investigation because the inducing effect of some of these steroids may be related to their contraceptive action. It is now recognised that the hormonal contraceptives owe their high efficacy to effects at a number of sites in the reproductive process and contraceptive efficacy can be obtained with doses of synthetic steroids which do not inhibit ovulation. Arthur and Chang suggest that administration of steroids during the pre-ovulatory phase of the cycle may change the uterine environment by induction of specific uterine proteins so that it will no longer support embryonic development and/or implantation. Furthermore it might be possible to develop compounds which have this effect but which would be without the adverse side effects associated with some of the hormonal contraceptives currently used. The idea is attractive but so far blastokinin has not been demonstrated in human uterine fluid.

The topologist meets the biologist

from a Correspondent

A MEETING on May 21-24 organised by the Mathematics Institute of the University of Warwick and sponsored by the Science Research Council was intended to initiate a dialogue between biologists, mainly in embryology and neurophysiology, and specialists in differential topology and dynamical systems.

The possibility of such a dialogue owes much to the efforts of C. H. Waddington (University of Edinburgh), R. Thom (Institute des Hautes Etudes Scientifiques, Paris) and E. C. Zeeman (University of Warwick). Waddington has for many years stressed that topology is a natural language for developmental biology. Thom sees his catastrophe theory as an essay towards an algebra of morphology, enriching the range of our ways of describing and classifying forms. His talk at the Warwick meeting was euphoric, aphoristic, enthralling and exasperating in turns.

Zeeman has taken on the task of convincing biologists, by means of concrete applications to problems they see as important, that catastrophe theory can be predictive. The reaction to his talk on amphibian gastrulation suggested that a fruitful dialogue has begun. A sequence of talks on development—by P. D. Nieuwkoop (State University of Utrecht), D. Ede (University of Glasgow), J. Cooke (National Institute for Medical Research, Mill Hill), J. Lewis (Middlesex Hospital Medical School, London) and P. Shelton (University of Leicester)—could have left the mathematicians in no doubt about the fascination and complexity of the regions into which they are venturing.

At other points the meeting turned more to debate between biologists, notably in a marathon session on hardware and software in perception, involving principally D. Marr (University of Cambridge), W. R. Adey (University of California, Los Angeles) and D. Sunday (California State University). It seemed that the brain is not ready for the topologists or that they are not ready for the brain.

One session was devoted to problems in which differential equation models have traditionally been used. Handling solutions of coupled ordinary differential equations as trajectories is an essentially topological procedure. So it seems very likely that the power and scope of models for interacting animal species, chemical oscillators and circadian rhythms can be greatly extended. In this session A. Winfree (Purdue University) revealed how illuminating it can be to apply topological reasoning to circadian rhythms and to travelling waves in chemical reactions.

Convection in a layered mantle

from Peter J. Smith
Geomagnetism Correspondent

SEISMIC data have revealed that the Earth's upper mantle contains several discontinuities in density and seismic velocity, the most prominent of which lies at a depth of about 650 km. But what constraints does the existence of such discontinuities place on the form and magnitude of the convention currents which are believed to share the same region of upper mantle space? The full answer to this question would depend on a complete knowledge of the nature of the transitions producing the discontinuities—a matter which is far from being resolved. Insofar as the discontinuous changes in physical properties are due to mineralogical phase transitions they are relatively well understood; and their effect on convection is probably quite small. Richter (*Rev. Geophys. Space Phys.*, **11**, 223; 1973), for example, has shown that the Rayleigh–Benard convection driven solely by unstable vertical temperature gradients, the presence of the olivine–spinel phase transformation does not alter the structure of the flow and produces a roughly two-fold increase in steady amplitude. But if, in addition, chemical changes are involved, the problem changes because the position of the critical boundary will depend not on state parameters but on advection.

The question of whether or not the mantle is chemically inhomogeneous is still a matter of debate, although there must be a strong presumption in its favour. Press (in *The Nature of the Solid Earth*, McGraw-Hill, 1972), for example, investigated bulk sound velocity as a function of density for a set of Earth models obtained using Monte Carlo techniques and concluded that an offset in the velocity–density plot near the 650 km phase transition represents an increase in the Fe/Mg ratio. Several other workers have reached similar conclusions, although such agreement is not necessarily as impressive as it seems because there are known to be certain problems associated with the determination of mean atomic weight using bulk velocity–density data. Moreover Wang (*J. geophys. Res.*, **75**, 3264; 1970) has shown that it is possible to find an Earth model with a chemically homogeneous upper mantle which is quite consistent with free oscillation data. Anderson and Jordan (*Phys. Earth Planet. Interiors*, **3**, 23; 1970), on the other hand, support iron enrichment of the lower mantle using several methods which are apparently not open to the objections directed at bulk velocity–density systematics.

In summary, then, chemical stratification in the upper mantle, though not proven, is highly likely; and so it is important to investigate what effects such layering is likely to have on convection processes. Richter and Johnson (*J. geophys. Res.*, **79**, 1635; 1974) have now attempted to do this by analysing the stability, to heating from below, of a system comprising two immiscible fluid layers of different density separated by a boundary which will be advected by the flow. What emerges from the fluid dynamical analysis is a stability diagram for the system showing the critical Rayleigh number (that is, the critical value of the normal Rayleigh number, R_a) for the most unstable mode as a function of R_ρ, the Rayleigh number based on the density contrast between layers. In other words, the stability diagram is a curve in R_aR_ρ space which separates the stable region below (towards lower R_a, R_ρ values) from the unstable region about (towards higher R_a, R_ρ values). In this context, stability means that at a given point in R_a-R_ρ space all perturbations decay with time.

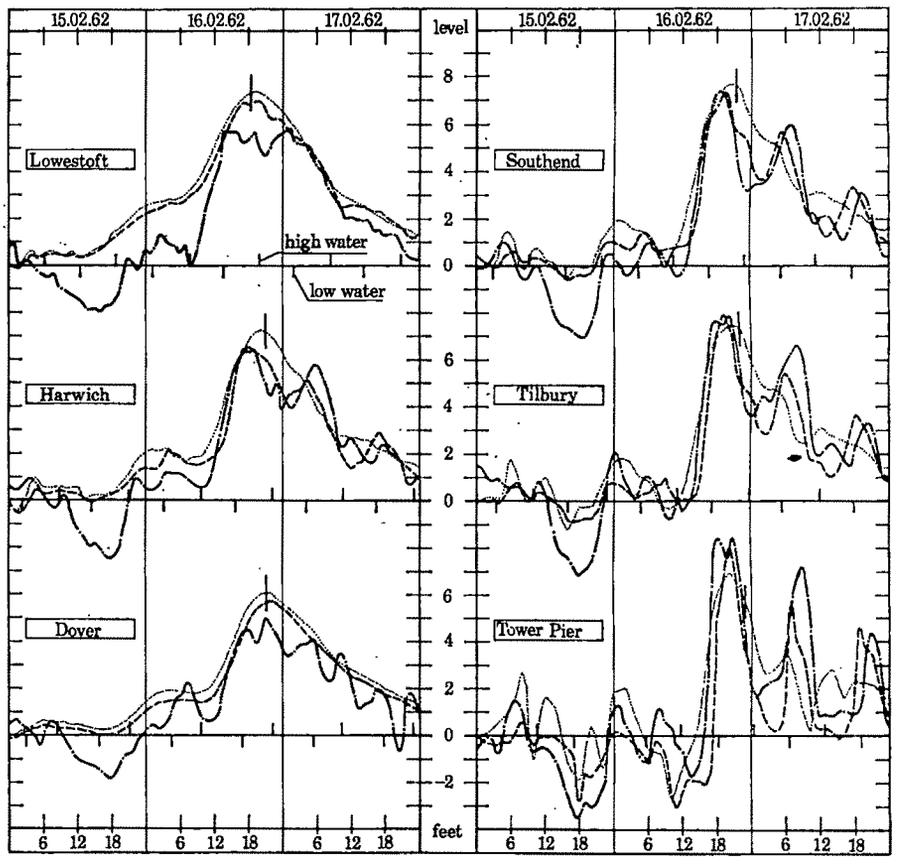
For R_ρ lower than about 5×10^3, the most unstable mode is a standing oscillation on the interface between the two layers (overstable mode); and once the oscillatory motion begins, the fluid never returns to a state of total immobility. This overstable regime only exists within a very narrow band of R_a values, however, suggesting that its occurrence is not very probable. Below this band (lower R_a) the system is stable, but above it (R_a higher than about 10^4) direct convection throughout the entire depth of fluid (that is, throughout both layers) becomes possible. If such convection were actually to take place it would, of course, destroy the original chemical layering; conversely the persistence of a chemical boundary precludes total-depth convection. For R_ρ higher than about 5×10^3 the situation is quite different. In this region the most unstable mode comprises separate convection within each layer and is thus independent of the density jump across the boundary between the layers. The stability curve separating the stable and unstable regions in R_a-R_ρ space is now parallel to the R_ρ axis, and so the stability or instability of the system depends only on the value of R_a.

These results place important bounds on acceptable Earth models. If the overstable mode is ruled out as improbable, for a model in which R_ρ is lower than 5×10^3 the occurrence of convection is consistent with the continued presence of a chemical boundary because the convection would cross the boundary and chemically homogenise the system. Thus in a model in which both convection and chemical layering are inferred, R_ρ must be higher than 5×10^3—and in this case there will be separate convection within each layer. In the case of the real Earth, much therefore depends on whether the 650 km discontinuity is just a phase change or whether it represents the combined effect of a phase transformation and a chemical change. Assuming that a chemical change is indeed present and that it involves an increase in iron relative to magnesium, several authors have calculated that R_ρ would be of the order of 10^6. This clearly implies that convention may only occur separately above and below a depth of about 650 km.

This result does much to emphasise the importance of resolving the problem of whether or not the upper mantle is chemically inhomogeneous. The convective motions for seafloor spreading are likely to be those in the uppermost layer, and the thickness of this layer will influence the magnitude of the convective cells within it. Richter (*Rev. Geophys. Space Phys.*, **11**, 223; 1973), for example, showed that many of the possible flows in the mantle have horizontal scales comparable with the depth scale. The fact that the depth scale may be governed by the presence of chemical layering clearly makes it necessary to determine whether or not such layering actually exists.

Modeling tide and surge interaction

from J. Darbyshire



GREAT disasters and natural upheavals often provide an incentive for scientific research and this has been very true in the investigation of storm surges (or the extra tides caused by meteorological effects). The first such stimulus was probably the great Thames flood of 1928 which led to the systematic recording of these effects at Southend and to work on their prediction at the Bidston Observatory near Birkenhead. The methods originally used were largely empirical and the work of Doodson and Corkan was very important during this period.

The next great stimulus was the disastrous flooding of the English east coast and the Dutch coast during January 31–February 1, 1953, when many lives were lost and many of the Dutch dykes were seriously breached. After this there was set up at the British Meteorological Office, a flood warning system which made use of the fact that tidal abnormalities on the English side of the southern North Sea are usually preceded by similar smaller but detectable abnormalities at Aberdeen about 9 h earlier. This would give an even longer warning to the continental

coasts. The 1953 surge also led to a spate of research. Rossiter published an article in the *Philosophical Transactions* which described very accurately the abnormalities at various times at all the ports on the circumference of the North Sea where tidal records were available. These results led to further attempts to improve methods of prediction and I was involved with one of them (J. and M. Darbyshire, *Proc. R. Soc.*, **A235**, 260–274; 1956). Hansen of Hamburg, on the basis of these observations, produced (*Tellus*, **8**, 287–300; 1956) the first mathematical model based on the use of digital computers and achieved a very high measure of success. The storage capacity of computers of this period were, however, rather too limited to cope with the hundreds of equations involved in finite difference methods and Ishiguro of the National Institute of Oceanography devised methods based on an electrical analogue of the North Sea which were to prove very useful (*Storm Surges in the North Sea—An Electronic Model Approach*, report 4, paper 25 (iii), Advisory Committee on Oceanographic and Meteorological Research; 1966).

The research effort in Britain, however, was still largely centred at the Liverpool Tidal Observatory at Bidston (later on to become the Institute of Coastal Oceanography and Tides and now a part of the Institute of Oceanographic Sciences) and the lead of the late J. R. Rossiter in this field will always be remembered. The work was extended to river estuaries, particularly the Thames, but it soon became evident that there was a large interaction effect between tide and surge which could not be ignored. Proudman had already predicted this on theoretical grounds. A computer model of the Thames based on these considerations was produced by Rossiter and subsequently Rossiter and Lennon. Models of the North Sea had ignored this interaction effect, but a new article by Joyce Banks, also from Bidston, extends the river model into the southern North Sea and allows for the effect of tidal interaction (*Phil. Trans. R. Soc.*, **A275**, 567–609; 1974).

Banks confines the investigation to the period of the notorious Hamburg surge of February 1962. In the figure is reproduced part of one of her diagrams which shows a comparison of observed surge effects at various English ports with predictions based on her model both with and without allowance for tidal interaction. An examination of the results shows that the tidal effect is very small in the open sea and the only appreciable difference is at Tower Pier. The initial negative surge is not successfully predicted and this is probably due to its being caused by conditions outside the southern North Sea and not accounted for by the model.

Time variations in wind-induced sea levels of the Hamburg surge at British ports. –.–, Observed residual elevation after removal of the barometric surge; – –, surge level ξ_{5+1} computed on the basis of wind and tide; . . . . , wind surge ξ_5 computed in the absence of a tide. Times of high and low water of the total predicted tide are marked along the abscissae. The vertical line near the peak surge corresponds to the time of high water of the computed lunar tide.

It seems a very far cry from the early empirical days to the modern highly sophisticated computer methods, yet a prediction of the surge at Lowestoft for February 1962, based on my very simple formula published in 1956, compares very favourably with that storm in the figure and as the formula took some account of conditions in the northern North Sea, the results do show a slight initial negative surge. Empirical methods, although very useful from a practical point of view, do not, however, help a great deal to gain a fuller understanding of the fundamental processes involved.

Randomness in evolution

from A. Hallam
Palaeontology Correspondent

HISTORICAL events can be studied in two radically different ways. Each individual event can be considered on its own merits, and interpreted independently, or many such events can be dealt with collectively, with a view to formulating general laws. The first type of approach can be termed idiographic and the second nomothetic. All historical events have both idiographic and nomothetic aspects, but palaeontologists have traditionally focused on the former. With regard to the major question of evolutionary diversification and extinction of particular fossil groups, a wide variety of patterns has been recognised, but little success has been achieved in attributing these to specific causes or in creating general models with predictive power. Consequently several American workers have recently adopted the nomothetic approach, to test the possibility that some aspects of the evolutionary record behave as stochastic or random variables. Each event may depend on the joint occurrence of many underlying genetic, morphological, physiological and ecological causes but the event itself may only be predictable statistically, even though it has a conventional cause. The analogy of the gas laws in physics comes to mind, with each fossil taxon playing the part of individual gas molecules.

Van Valen, in the first number of a new journal called *Evolutionary Theory* (July 1973), tackled the problem of faunal extinctions by applying the

survivorship curve technique of population ecology, which is a simple plot of the proportion of the original sample that survives for various intervals of time. The use of a logarithmic ordinate ensures that the slope of the curve at any given age is proportional to the probability of extinction at that age. Van Valen's analyses of numerous taxa showed almost uniform linearity in the survivorship curves, allowing for sampling error. This is rather surprising, because it requires that the probability of fossil discovery does not decrease appreciably with the age of the strata, as has been argued by Raup in an article in *Science* (**117**, 1065; 1972); also because, for living taxa, both constant origination and extinction rates are implied. Van Valen is led on to propose a new evolutionary 'law', that extinction in any adaptive zone occurs at a stochastically constant rate. Exceptions to the 'law' are considered to be either spurious, rare or doubtful. He also proposes a new unit to measure the rate of extinction, the macarthur, named after a well known American evolutionary ecologist.

Raup, Gould, Schopf and Simberloff adopt a different approach in the *Journal of Geology* (**81**, 525; 1973) to the more general question of diversification and extinction, by using a computer to generate phylogenetic diagrams, or cladograms. The lineage of each clade, or monophyletic subunit, was generated by the computer program and caused to terminate or branch in order to produce a hypothetical phylogeny, with the termination and branching events being stochastically controlled using random numbers. Part of the input dealt with the establishment of an equilibrium diversity, in accord with modern evolutionary theory. The cladograms so produced exhibit a great variety of shapes: some underwent early exponential increase in diversity and then declined gradually to extinction (the trilobites); others showed a gradual diversity increase followed by a rapid extinction (dinosaurs) or passed through a near-extinction phase to develop a new phase of high diversity (ammonites). The average extinct clade increases in diversity up to the mid point of its stratigraphical range and then declines in diversity until extinction. When faced with such variation in pattern many palaeontologists have been inclined to suspect or postulate that the organisms in question were inherently different in evolutionary potential. The observed variation does not exclude, but nor does it demand this. Comparison with a real example, the fossil record of the reptiles, shows good general agreement but also some interesting differences. Thus the late Cretaceous extinctions showed more coincidence between different groups than predicted from the computer model.

It seems therefore that an exceedingly simple stochastic model can produce branching and diversity patterns very similar to those described in the real world; also that the taxonomy utilised by palaeontologists imposes various constraints similar to those used in the logic of the computer program. The question arises, where does one go from here? In the first place palaeontologists should be even more suspicious of any glib deterministic explanation of the diversification and extinction of any particular fossil group. More positively, there is a more sophisticated tool for investigating the extent to which the coincidence in time of extinction of different fossil groups departs from randomness. This should be easy to demonstrate for the striking mass extinctions at the end of the Permian and Cretaceous, but what of the other geological periods?

Two dimensional rotons

from Peter V. E. McClintock
Condensed Matter Correspondent

A ROTON in a two-dimensional assembly of helium atoms has a smaller energy than a roton in three dimensions, according to a calculation by Padmore of Erindale College, University of Toronto (*Phys. Rev. Lett.*, **32**, 826; 1974).

The thermodynamic properties of bulk liquid helium below its superfluid transition temperature can be understood reasonably well on the basis of a model, due to Landau, in which it is assumed that the thermal energy is all in the form of a gas of particle-like excitations moving through the superfluid, which plays the part of an inert background or aether. There are two main types of excitation: phonons, which are quantised sound waves much like those occurring in solids; and rotons, which are peculiar to liquid helium and are believed to correspond to some sort of stirring motions on the atomic scale, such as microscopic vortex rings. There is, as yet, no agreement as to the precise physical nature of rotons, but their detailed energy–momentum relationship, known as the excitation spectrum, has been established through neutron scattering experiments and is consistent to a high precision with the measured heat capacity of the liquid.

Although attempts to deduce the excitation spectrum theoretically from first principles for an assembly of weakly interacting helium atoms have not been very successful, Feynman and Cohen (*Phys. Rev.*, **102**, 1189; 1956) managed to derive a spectrum of the correct general shape and approximately in quantitative agreement with experiment, by using quantum mechanics. Their approach involved to a considerable extent the use of physical intuition to develop a wave function able to describe the superfluid background, and they then used a so-called trial wave function, not specified in detail, in order to describe the elementary excitations. A variational method was used to investigate how the trial wave function should be modified in order to minimise the energy of the whole assembly, and thus discover the true wave function from which the excitation spectrum could then be derived. Padmore has extended the Feynman and Cohen approach in an attempt to derive theoretically the excitation spectrum of a two-dimensional (2D) assembly of helium atoms.

Assemblies which are effectively 2D occur where one of two atomic layers of helium are deposited on a solid surface. The helium atoms are held in place by the attractive Van der Waals force which prevents them from moving in a direction perpendicular to the surface; but they can remain completely free to move parallel to the surface. Under appropriate conditions of density and temperature, such assemblies have been shown to form either 2D crystalline solids, or liquids, or gases. By using, for the substrate, materials such as exfoliated graphite or Vycor glass which have very large surface areas in relation to their volumes, it is possible to measure the heat capacity of 2D liquid helium, and experiments have shown that the heat capacity appears to be anomalously large. A possible explanation lies in the idea that rotons can still exist in a 2D assembly, but with smaller energies than they have in 3D. A neutron scattering experiment to measure the excitation spectrum does not seem possible because of the random orientations of different sections of the substrate, so a calculation of the spectrum is therefore of particular interest.

The most important conclusion which emerges from Padmore's calculation is that the energy of a roton in 2D is indeed considerably less than in 3D. Although the calculated roton energy, is, as in the 3D case, still somewhat larger than would be consistent with the measured heat capacity, the change in energy in going from 3D to 2D seems to be in excellent agreement with the relatively few experimental data at present available. Padmore also reports his calculated characteristics for rotons in 2D helium at a number of different densities, so no doubt there will soon be reports of further experiments aimed at checking these more detailed conclusions.

Accurate spectroscopic factors

from Peter E. Hodgson
Nuclear Theory Correspondent

DURING the past ten years the one-nucleon transfer reactions have been developed into one of the most powerful tools for studying the single-particle aspects of nuclear structure. Among these the (d,p) reaction has been most widely used, but extensive studies have also been made using (d,n), (p,d), (d,t), (d,h) and many similar reactions that either add a proton or neutron to or remove one from the target nucleus.

As a typical example, consider the (d,p) reaction on ^{24}Mg. The incident deuteron interacts with the ^{24}Mg target and deposits a neutron in one of the unoccupied neutron states, and the remaining proton goes on alone. At lower energies this process can take place by absorption of the deuteron to form a compound nucleus followed a long time after by proton emission, but at higher energies the direct process that takes place in a time comparable with the time taken by the deuteron to cross the target nucleus predominates to such an extent that the compound nucleus process is negligible.

The differential cross section for this direct (d,p) reaction can be written as the product of two factors, one depending only on the structure of the nuclei involved and the other only on the reaction mechanism:

$$[d\sigma/d\Omega] = S_{JL} F_{JL}(\theta,E)$$

All the dependence of the cross section on the angle of emission θ of the proton and on the incident deuteron energy E is contained in the reaction factor $F_{JL}(\theta,E)$, and this can be calculated by the distorted wave theory. These angular distributions are in general characteristic of the total quantum number J and orbital angular momentum quantum number L of the state entered by the captured neutron so that comparison between the observed angular distribution and those calculated for various J and L enable these quantum numbers to be determined, and these give the spins of the corresponding states of ^{25}Mg.

The spectroscopic factor S_{JL} is a measure of the single-particle strength of the neutron state and is given by the ratio of the measured cross-sections to the calculated value of the $F_{JL}(\theta,E)$.

The analysis is thus able to give the quantum numbers and the single-particle strengths of all the nuclear states of ^{25}Mg reached by the reaction. Numerous analyses of nuclear states in all stable nuclei have been made with this technique, and it is one of our main sources of information on nuclear structure. The main limitations to this method are, first, that it is not always possible to determine J and L and, second, that the uncertainties in the distorted wave theory make the spectroscopic factors uncertain to about 20%, even in the best circumstances.

A new method of analysing one-nucleon transfer reactions has now been proposed by C. F. Clement of Harwell (*Nucl. Phys.*, **A213**, 469 and 493; 1973) and used to obtain more reliable J,L and more accurate spectroscopic factors. This method depends on the j-dependent sum rules that relate the spectroscopic factors of the reactions that remove a neutron (or proton) from a nucleus to the spectroscopic factors for the corresponding reaction that adds a neutron to the same nucleus. The j is the total angular momentum of the transferred nucleon. These sum rules provide a rigid set of equations that must be satisfied by the spins of the final states and by the spectroscopic factors of the corresponding transitions.

These sum rules must be distinguished from the more familiar J-dependent total sum rules that relate the spectroscopic factors to the total single-particle strengths of the states. The j-dependent sum rules provide additional constraints on the spectroscopic factors only if the spin of the ground state of the target nucleus is different from zero; if it is zero they are the same as the total sum rules. The method is thus applicable only to nuclei with ground state spins different from zero. All these sum rules were derived long ago by J. P. French, but it is only recently that they have been applied to nuclear structure analyses.

Clement and Perez (*Nucl. Phys.*, **A213**, 510; 1973) have now applied this analysis to the reactions (d,t) and (d,p) that remove neutrons from or add them to the states of ^{45}Sc with spin 7/2. The sum rules give a set of eight equations connecting sixteen sums of spectroscopic factors for stripping and pick-up to states of different spin. The measured spectroscopic factors satisfied these equations to an accuracy of 4% in relative magnitude and 10% in absolute magnitude. Several additional spin assignments to states of the residual nuclei ^{46}Sc and ^{44}Sc were made by this analysis.

An important problem in all analyses of single-particle states is the fraction of the strength that is far removed from the main concentration. Clement and Perez find that it would be difficult to maintain their fits to the sum rules if more than 10% of the total is in the continuum. Thus nearly all the f7/2 strength is concentrated in a limited energy region; this is an important conclusion for the basic single-particle model of nuclear structure and supports the validity of the distorted wave theory.

Subsequently Clement and Perez have applied the sum rule analysis to other nuclei and have still further reduced the uncertainties in the absolute spectroscopic factors. This is clearly a technique of great power that can provide valuable information on nuclear structure and stringent tests of the present techniques for obtaining it.

Fitting the flower to the bee

from a Correspondent

WITH the increasing use of F$_1$ hybrids in insect-pollinated agricultural crops and vegetables, special methods have to be devised to get enough effective pollinating insect visitors to achieve the complete cross fertilisation that is necessary. At the Third International Symposium on Pollination organised in Prague from May 15-18 by the International Commission for Bee Botany of IUBS, the Bee Research Association and the Academy of Agricultural Sciences and other bodies in Czechoslovakia, examples discussed included red clover, lucerne, field bean, melon and cucumber. A detailed knowledge of floral biology, pollen and nectar production, and their composition is needed; for instance, Ing. H. Haslbachová (College of Agriculture, Brno) reported success in increasing pollination (and hence seed yield) in tetraploid red clover by applying growth regulators which alter the morphology of the subsequent flowers in ways which make them easier for the bees to work.

Visitation by bees is necessary for good crops of strawberries from some cultivars, and L. J. Connor (Ohio State University) has found that the number of visits a flower receives depends on its structure. Flowers with stamens short in relation to the receptacle are difficult to work and not much visited. Unfortunately the first flower on a stem (giving the earliest, most profitable, fruit crop) has short stamens, even in cultivars whose later flowers have long stamens. Here the most likely solution is breeding plants for floral morphology that suits the pollinating bees.

G. D. Waller (US Department of Agriculture Laboratory, Tucson), in seeking to find out why it is difficult to achieve adequate pollination in onion seed plots (*Allium cepa*), found that honeybees—the major pollinator—are unwilling to forage on the onion flowers. The only difference between these flowers and others available nearby is that the potassium concentration of the onion nectar is about ten times as high as that of other nectars. An interspecific hybrid *Allium cepa* × *A. fistulosum* produces nectar with a normal potassium

content and is very attractive to honeybees. These results provide the first evidence that a minor constituent of nectar can significantly inhibit its collection by honeybees.

Much less is known about pollination in the tropics than in temperate regions, though an even higher proportion of tropical crops probably depend on insect pollination. S. E. McGregor (USDA Laboratory, Tucson) presented a list of 120 such crops, belonging to 39 botanical families. T. Chandler, a Canadian currently working at the Forestry Training Institute, Arusha, Tanzania, has studied pollination of lucerne by the African honeybee *Apis mellifera adansonii*, which has come in for much reprobation recently on account of its aggressive (or defensive) behaviour. This subspecies proves much more effective than the European ones at 'tripping' the flower, and thus pollinating it, largely because lucerne pollen is attractive to them, whereas other pollens are preferred by European honeybees. Also, the African honeybees are efficient at detecting which florets are at the right stage for tripping, and thus do not waste time visiting those that were too immature.

Work by Mackensen and Nye on breeding *Apis mellifera* specifically for collecting pollen from lucerne has now been successfully extended to red clover by H. Nørgaard Holm in Denmark (Højbakkegård, Tåstrup).

Since the second pollination symposium in London in 1964, commercial rearing of certain species of soil-nesting and stem-nesting bees has progressed beyond all expectation. Reports came of work in Canada, United States, France, Hungary, Czechoslovakia and other countries. From Poland L. Bornus and his colleagues (Beekeeping Institute, Puławy) brought news of the highly successful rearing of bumblebees for pollination, achieved largely by careful determination of these bees' preferences at each stage of their seasonal cycle.

In an account of the first 25 years of the Bee Research Association at Chalfont St Peter, Buckinghamshire, Eva Crane reported that a 23-year index to research reported in its journal *Apicultural Abstracts* (1950-1972) has just been completed. The information is stored on magnetic tape, and it is hoped to publish it as author and subject catalogues, linked to abstracts in the journal. The 17,000 publications represented include many giving information on pollination, and a volume *Pollination of Seed Crops*, based on publications reported in *Apicultural Abstracts*, has already appeared. Estimates of the world value of crops resulting from insect pollination vary from £1,000M to £10,000M a year or more.

Gap junction between cells in contact

from a Correspondent

ALL cells in tissues and all but two of twenty-five cultured cell lines form junctions with one another and communicate through these junctions by transfer of electrical signals and chemical substances (the latter was originally termed metabolic cooperation). The junctions form extremely rapidly, within a minute certainly, and presumably break just as rapidly. Cells therefore are constantly forming and breaking contacts for metabolic cooperation and intercytoplasmic exchange. The relevance of such processes to inductive interactions during tissue differentiation and embryogenesis makes this one of the newest and perhaps most interesting areas in biology. The Cell Surfaces Discussion Group held a timely meeting on May 23 at the National Institute for Medical Research, Mill Hill on the structure and function of intercellular junctions.

The particular consideration of the meeting was the gap junction between cells in contact, permitting the flow of matter across the membranes between two cells. E. L. Benedetti (Institute of Molecular Biology, Paris) catalogued interesting similarities and differences between the propagation of an electric current between cells and passage of chemical tracers. Thus both electric coupling and chemical transfer are bidirectional and operate across the same junction. Some separation of these events is implied, however, since the former is present in most embryonic cells, excitable and non-excitable, and there may be some restraint of chemical transfer in embryonic tissues.

The inability to form gap junctions is also seen in some cell lines such as L fibroblasts, for example, and this is recessive in cell hybrids. Thus, heterokaryons with human fibroblasts can electrically and chemically couple and revertants that lack part of the complement of human chromosomes first lose competence for passage of chemical markers across the gap junction and subsequently the capacity for electrical coupling.

The types of chemicals transported across gap junctions is quite wide, but, as was emphasised by J. Pitts (University of Glasgow), there is an upper molecular weight limit of about 1,000. The flux of a metabolite, such as a purine nucleotide, is calculated to be about 10^5–10^6 molecules s^{-1} across the gap junction, that is about equivalent to the *Escherichia coli* chromosome. The capacity of mouse fibroblasts to form gap junctions may not be lost irretrievably and it is possible to select for 'revertant' cells that form junctions, but not as efficiently as say BHK cells.

E. Wright (Institute of Virology, University of Glasgow) described experiments that set out to isolate BHK cell mutants incapable of forming competent junctions. The basis of the selection is to cocultivate BHK wild type cells with a thymidine kinase negative mutant and BUdR and to isolate cells which survive ultraviolet irradiation. Interestingly, although these mutants (*Mec*$^-$) as expected are extremely poor recipients of thymidine from a BHK wild type cell population, metabolic cooperation can be established if a purine marker such as adenine is used so that there seems to be discrimination between the passage of two nucleosides across the gap junction.

As both Pitts and Wright agree, the idea that the many metabolites capable of passage across the gap junction may require independent transport processes is extremely difficult to reconcile with the evidence that purified gap junctions appear to contain relatively few proteins. For example, W. H. Evans (National Institute for Medical Research, Mill Hill) finds one major protein of molecular weight 29,000 in fractions of mouse liver plasma membrances enriched in gap junctions. Similar results were reported for synaptic junctional complexes by I. Morgan (Centre de Neurochemie, CNRS, Strasburg) and A. Matus (University College, London). The most common method of preparation, however, involves detergent solubilisation of the non-junctional areas of membrane and it may be that some dissolution of junctional membrane components may also take place.

The mechanism of formation of gap junctions remains obscure. Since junctions can form in the absence of protein synthesis, pre-existing membrane proteins are utilised. The junctional areas, however, are clearly differentiated from the rest of the membrane by the absence both of typical enzyme markers such as 5′-nucleotidase and leucyl napthylamidase and most of the plasma membrane proteins and glycoproteins. It must be assumed, therefore, that the initial events in junction formation requires the clustering of specific junctional proteins by lateral diffusion in the surface membrane.

The association of cytoplasmic contractile elements with gap junctions now seems established. One supportive result is the probable identity of an actin-like protein in preparations of mouse liver gap junctions. The role of these elements in formation maintenance and function of the gap junction, however, remains to be elucidated.

energy review

How Britain is facing the energy problem

"Our energy strategy must be flexible, balancing between different fuels and different sources, steering between overcaution and recklessness." Mr Eric Varley, Secretary of State for Energy, gives his view of the situation.

THIS edition of *Nature* devoted to energy matters is very timely. The problems which we face in this field are complex and far-reaching and, as Secretary of State for Energy, I am concerned that they should be as widely understood and thought about as possible. My department was set up in the midst of crises and its first six months have inevitably been preoccupied with the transition to greater stability. But we are now tackling the problems—many of them pressing—of the longer term. Public discussion of the problems involved is very important, particularly among scientists and technologists whose contribution to their solution can be very great.

The broad context of these problems is familiar. Consumption of energy on a large scale is part of the fabric of our society. Last year Britain consumed the equivalent of 342 million tons of coal, with oil (159 million tons of coal equivalent) and coal (131 million tons) the largest components: and in the past every extra 1% of GDP has been accompanied by increased energy consumption equivalent to about two million tons of coal. We have to plan far ahead to continue to meet these needs as securely, flexibly and cheaply as possible in a way which allows continuing economic growth. But whereas our consumption patterns reflect past access to cheap and plentiful supplies of energy, we must now accept that energy is an expensive commodity; that more active policies are needed nationally and internationally to achieve security and availability; and that much more attention needs to be paid to the way we use our energy, cutting out waste and improving efficiency.

Coal and oil

Development of our indigenous resources must be a key factor in our strategy. It is already apparent that these resources are very substantial and that, though we still do not know their full extent, they can make a very major contribution to our energy supplies and, more broadly, to the strength of our economy. But there is a wide range of important and testing problems to be solved in bringing them forward and in making the best possible use of them.

We have much the biggest coal industry in western Europe, despite its decline during the past decade or so, and the new energy situation has completely altered the framework in which its future is planned. It is already clear that coal must remain one of the main foundations of our energy policy and that the industry can look forward to a sure future. But a lot of work has to be done to ensure that its contribution is made most effectively. Just holding annual production from deep mines at its present level of around 120 million tons—and I hope to go above that if possible—will be a major task. One of my first acts on coming into office was therefore to announce the setting up of a full scale examination—involving government, the unions concerned, and the National Coal Board—of the contribution which coal can best make to Britain's future energy requirements and of the steps needed to secure this contribution. Good progress has been made and we hope we will have made an interim report by the end of this month.

Then there are all the resources of the North Sea. North Sea gas already supplies 90% of our gas consumption; and North Sea oil offers the prospect of a completely new source of oil supply, with all the advantages that that implies in the present world energy situation. It also offers us challenges, both in its development and, having brought it ashore, in making the best use of it. Nowhere else in the world has oil been brought up from these depths in these conditions, and great technological and engineering skill has to be brought into play to make sure that development proceeds as fast as possible. I am concerned not only to see that this feat is carried through successfully but also to develop policies which will ensure that oil and gas from the Continental Shelf are exploited in such a way as to confer maximum benefit on the community, particularly in Scotland and the regions elsewhere in need of development.

Nuclear prospects

Another major and difficult area is nuclear policy. Studies in depth and extensive deliberations about nuclear reactor choice have been in hand literally for years, without any clear consensus emerging. It is certainly an area of great technological complexity where the issues are not at all easy to weigh up. At the time of writing I have not come to, or announced, any decision. But I would stress that it is clear that there is no ideal solution.

The implications of the new energy situation are of course far reaching and certainly not confined to the problems of developing indigenous resources and nuclear power, and planning to meet long term demand. Many other issues are involved. One which I believe will, and must, increasingly impinge on the lives of everyone is the conservation of energy in the sense of cutting out unneces-

sary consumption and improving efficiency in use. Energy is now an expensive commodity and this fact alone will bring home to many people the need to use it thriftily. But the government has a role to play too, and this is another area where I want to do what I can to speed up and encourage adaptation to the new energy situation.

In every one of the areas which I have mentioned the role which science and technology must play is of great importance, in many instances fundamental. Indeed it is no exaggeration to say that science and technology must provide the key to the longer term future. And, because of the time scales involved, we have to be very farsighted in our approach. Well directed and effective decisions on research are therefore an essential part of energy policy.

There can be no doubt that the main thrust of research and development on energy in this country must continue to be nuclear, looking towards the fast breeder reactor and then, we hope, towards the very long term prospect of controlled nuclear fusion as an energy source. Nuclear technology is by far the most promising avenue to pursue, in terms of meeting the energy needs both of the United Kingdom and of the world as a whole. We are therefore investing substantial sums in the nuclear field and are actively seeking international collaboration to ensure rapid advance at minimum cost. I recognise the misgivings which some people have about the safety of nuclear power. It is a matter to which I attach the greatest importance and I recognise my responsibility to uphold the very high safety standards which have been established in Britain.

Other possibilities

Nuclear power is not of course the only possible option. Readers of the technical press will be familiar with a wide range of other possibilities being championed: for instance 'natural' sources, using energy from the Sun, tides, wind, waves and geothermal heat. But the development costs of these different technologies are likely to be high. We already spend more than £100 million each year in the United Kingdom on energy research and development, and we do not have unlimited resources. Moreover we should not feel that the United Kingdom must develop every technology for itself; in many cases international collaboration makes good sense and in some cases the best course may even be to import the developed technology.

Engineers and scientists in my department have examined the whole range of these other technologies in the energy sector which we might back, and, in collaboration with other departments, they have made detailed studies of the most promising options. They have paid attention to the possible scale of each technology in relation to our energy needs, the cost and time for development, and the possibility of successful exploitation, as well as to the likely impact on the environment. Their conclusion has been that none of the various possibilities shows sufficient promise to warrant large scale investment in research and development at this stage. It has to be remembered that many of these new sources would be in competition with nuclear power, as a source of electricity, and not with fossil fuels; so that their attractiveness in economic terms is not affected one way or the other by the rise in oil prices.

Nevertheless, this is an area where assessment is a continuing process. I have, for instance, felt that some further work on recurring energy is warranted as a form of insurance policy and I have accordingly commissioned a more detailed study of the prospects of extracting energy from sea waves: wave power is not expected to compete economically with nuclear power but it is an energy source particularly suited to the United Kingdom, with surprisingly large potential. I have also recently set up a team of scientists and engineers at Harwell to examine the many technological options and to ensure that our conclusions are soundly based. I recognise the importance to our future energy supply of getting these conclusions right.

We must adopt a quantitative approach to the big and far reaching decisions that have to be taken over the whole field of energy. Primary weight has to be given to the normal economic tests; energy is not the only scarce resource and an economic appraisal—provided we use realistic prices and, where necessary, take account of resource costs—enables resources of many different kinds to be weighed in the same scales. We know, of course, that these tests never tell the whole story. The calculations are only as good as the assumptions on which they are based. And we must have at the back of our minds other more nebulous considerations; with some, like security of supply, satisfactory quantification may be difficult, and with some, like the needs of future generations for energy supplies, it may be virtually impossible. But we must take the best account of them we can, while bearing in mind that, if we do decide to go down paths other than those indicated by the economic tests, we must be clear we are doing so for good and sufficient reasons.

Finally we must face the problem of taking decisions involving very long time scales. Over a long period the whole framework can change radically. On occasions it may change abruptly, as it did for oil last October. We are, therefore, very much in the business of risk taking. Not only can we not be sure that we have the answers, we cannot even be sure that we know the problems. It is for these reasons that our energy strategy must be flexible, balancing between different fuels and different sources, steering between overcaution and recklessness. However much any of us may think that we have the right answer, we cannot know for sure.

Towards rational energy policies

Lord Robens
Vickers House, Millbank Tower, Millbank, London SW7P 4RA, UK

"It is nonsensical to treat coal, gas, electricity, oil and nuclear energy as separate fuels without regard to the overall needs of Britain, and that is what has happened up to now. We should set up a National Fuel and Power Council to develop a coordinated and comprehensive policy for all the industries concerned".

It was in 1957 that I was involved with a small group of people, including some distinguished scientists, in having a look at, amongst other things, the future policy for energy for the United Kingdom. We had then, of course, no knowledge of what was going to come nearly twenty years later, but we did make that declaration and nothing that has happened since has shaken my belief in it. In fact the recent events in the Middle

East, which brought the western world almost to its knees and certainly quadrupled the price of oil, has strengthened my conviction of the importance of a permanent Energy Commission; its terms of reference today should be to make the United Kingdom completely independent of energy supplies from abroad at the earliest possible date.

North Sea gas and North Sea oil, which will begin to come into Britain very shortly, are additions to the other available energy sources that we have, the main one of course being coal, with nuclear power moving up. It is now generally accepted that the rundown of the coal industry during the 1960s was a grievous error. We made ourselves more and more dependent on outside sources for our energy requirements and not only handed over to the Middle East oil-producing countries control of our industrial production, but added considerably to our balance of payments problem. We now have the opportunity of complete independence and excellent energy export prospects. But this has to be carefully planned, because the relationship between coal, nuclear power, North Sea gas and North Sea oil should be so arranged as to maximise the life of oil and gas, while the opportunity is provided for nuclear power to make a gradual increase to the energy requirements of the nation.

First, I believe we must begin with the coal industry and ensure that its size is no longer dominated by the price factor, which determined its future from the latter part of the 1950s to date.

There should be established a target output for coal for the next 20 to 30 years. Coal production means long term planning. There is not only the question of planning the exploitation of the reserves and the constant replacement of the reserves to make good the annual extraction, but also the much more difficult and sensitive problem of planning for manpower requirements over several generations ahead. This involves immense human problems and social problems and cannot be adequately planned unless there is a guaranteed annual output.

There are two things that are absolutely essential if one is to maintain energy independence for all time—energy planning independent of Whitehall and international research on energy resources. The present method of planning by the Civil Service within a department is hardly likely to succeed. There must be serious doubts about the efficacy of the present machinery in Whitehall for resolving the kind of problems that emerge when one is considering four suppliers of energy, and the contribution that each have to make over the years ahead, and the life expectancy and economics of each of those sources of energy. If the government were wise, it would set up an Energy Commission right away to oversee the whole energy field and be responsible for advising ministers on strategy and tactics. If the Department of Energy decides to produce an energy policy from its own resources, it will assuredly fail as miserably as its predecessor failed with the Energy White Paper of 1967. The resources of the ministry are inadequate to do the enormous task of this long term planning.

The Civil Servants concerned with the writing of the 1967 policy are no longer there to face the consequences of the impotence of the 1967 White Paper. Some are retired, some are engaged elsewhere. The Civil Service approach to problems lacks continuity, and this is an inadequate approach. No *ad hoc* consideration can possibly perform the task of a continuing review. What is needed is an Energy Commission, whose task it would be to advise the government on energy policy and undertake comprehensive studies. The commission would be a continuing authority, staffed by experts in fuel economics and the specialist technologies. The commission, having no particular axe to grind, would be able to produce objectively an energy policy planned entirely in the national interest. It would do the total sum, taking into account all the knowledge now available as to the quantities of indigenous gas, oil and coal, and the expected contribution of nuclear power.

It would be able to ensure that capital investment was directed into those channels of energy development that would give the best return in national terms, rather than in a narrow advantage of one fuel over another. The infighting between the publicly owned energy industries would cease, as their place in the energy pattern would be properly established. Only an independent Energy Commission, in my view, would get the juxtaposition of coal, gas, electricity, oil and even nuclear energy about right. In an imperfect world, we cannot expect perfection although we can strive towards it; but like everything else, striving without the right tools would be a near hopeless task. An independent Energy Commission would be the right tool to do the job. There can be no doubt that such a commission would be able to create the plans and oversee the direction of those plans so as to provide the United Kingdom with independent sources of energy by the early 1980s.

The second very important approach must be to endeavour to secure an international research team into energy resources. Some time ago President Nixon set out on this trail, but I think failed because he invited too many countries to be involved. What I think is important is to set up an International Energy Council, whose purpose would be to mobilise the necessary teams for research. The object of the international research team would be to examine the possibilities of solar heat, oil and gas from coal, and oil from oil shale and tar sands. In these areas lie vast quantities of energy and although a good deal of the technology is already known, and makes a good starting point, a substantial amount of extra research work is required which is both costly in money and requires a very large group of fuel scientists and technicians. There is already a wide variety of work going on in Britain and in America to devise new routes for synthesising chemicals, oil and gas from coal. Research work in Britain has been concentrated on the development of the solvent extraction of coal and on digest extracts primarily as a route towards producing low volumes of high value and specialised products from coal. In America the basic theme of this work has been to apply solvent extraction and existing hydrogenation and other refining techniques to the synthesis of crude oil and natural gas as bulk sources of energy of raw materials.

These differing approaches have been dictated by the rather different relative economics of the coal and oil industries on either side of the Atlantic and by markedly different views about the security of petroleum supply.

Twenty-five years ago American energy planners had grasped the significance of the imbalance between gas and oil consumption and reserve availability. Historically the route towards chemicals and gas from coal has lain in coking. A typical feature, however, of traditional gas production from coke is the low calorific value—about 600 BTU per cubic foot—of the resultant product. Further notable features were the need for gas and coke markets to be in volume balance, and the highly fragmented localised nature of the coke-based gas-making industry enforced by maximum economic sizes of coke production units. In contrast, the discovery of natural gas has created a demand for gas of high calorific value, rich in methane, distributed from a relatively small number of sources through a trunk pipe line system.

As the years of North Sea gas begin to tail off, some quarter of a century from now, and where the demand for gas increases beyond economic production rates from North Sea sources, it will be necessary to synthesise what the Americans so aptly call pipeline gas, which can be blended in with North Sea supplies.

Already then we can see by an examination of the research work of the United States, and what is being done in Britain, that there is a great area of common knowledge and certainly a unified desire to retain energy independence. I believe, therefore, that it is highly important to press hard for international research work in these fields. There can be no doubt that the research scientists on both sides of the Atlantic will reach conclusions far quicker by working together than if they work independently.

The summary of my conclusions is, therefore:

- To reach complete independence for energy at the earliest possible date, and certainly not later than the early 1980s.
- To have an Energy Commission to advise the government on the way in which this objective can be achieved.
- To seek the greatest measure of international cooperation on research into the whole field of energy resources and energy uses in order to ensure that, despite the increase in energy demands year by year, world requirements of energy will be readily available.

North Sea oil in a world context

Frank Howitt

The British Petroleum Company Limited, Britannic House, London EC2Y 9BU, UK

Dr F. Howitt, of BP, assesses the oil and gas reserves which Britain can expect to exploit from the waters around its coastlines. Although supplies are limited, there seems to be some room for optimism: even if no more oil is discovered there may still be a small supply at the beginning of the next century.

DESPITE the fact that not a drop of indigenous regular production oil has reached UK shores from the North Sea, many people, myself included, are counting chickens. I want to put the results which have been obtained so far into the context of the present and potential production of the rest of the world. My statements and predictions are based on information collected by myself and my colleagues in the British Petroleum Company Limited.

Our conception of the general geological framework of the North Sea area is illustrated in Fig. 1. This shows the basins of sedimentation which developed after peneplanation following the Variscan orogeny (at the end of Carboniferous times) and which played the major role in providing the source and reservoir potential for most of the oil discovered so far. A conceptional cross-section illustrating stratigraphical succession, with major structural elements, relative thicknesses and current exploration 'plays' is shown in Fig. 2. Only very major faults and folds are illustrated, and Zechstein salt movement is idealised. The section is, however, drawn to scale particularly through chosen boreholes, although there is a vertical exaggeration of 60. The line of section is meant to go up the central median region, but in order to show major oilfield types it has been necessary to offset in places.

Occurrence of reservoirs

Despite the heavy exploration effort, during which 275 boreholes have been sunk since 1965 in the southern North Sea Basin, and the consequent discovery of some 42×10^{12} cubic feet of gas reserves, discoveries continue in the Permian Rotliegendes Sandstone. This is the same reservoir as that in the Leman Bank Field[1]. The gas is probably derived from the carbonisation of the coal in the underlying Coal Measures[2], and the structures are mostly sealed by overlying Zechstein salt[3]. One major gas discovery—the Hewett field—produces gas from two levels of Trias sands, in a structure that provided no seal at Zechstein level for the escaping Carboniferous gas. Naturally, the development of Rotliegendes sand facies to form the pre-Zechstein reservoir is a crucial general factor. Glennie[4] has argued plausibly that the reservoir sand formed essentially as a result of wind deflation of alluvial fans which spread northwards from the Variscan mountains.

Drilling in the northern North Sea Basin (about 200 exploration wells since 1969) has shown that three major 'plays' exist. The first is in the BP Forties Field, where there is oil in the Palaeocene sandstones[5]. This also seems to be the case in the nearby Montrose Field. Gas and condensates reportedly has been found also in the Tertiary sandstones of the Frigg, Heimdall and Cod Fields. The second 'play', which was the first to be discovered, is oil from the domed and fractured Upper Cretaceous and Danian chalks in the Ekofisk group of fields in Norwegian waters[6], and in the Dan Field in Danish waters. The third 'play' is oil from both the Jurassic sandstones in the far northern waters, where the Brent Field was the first discovery, and apparently

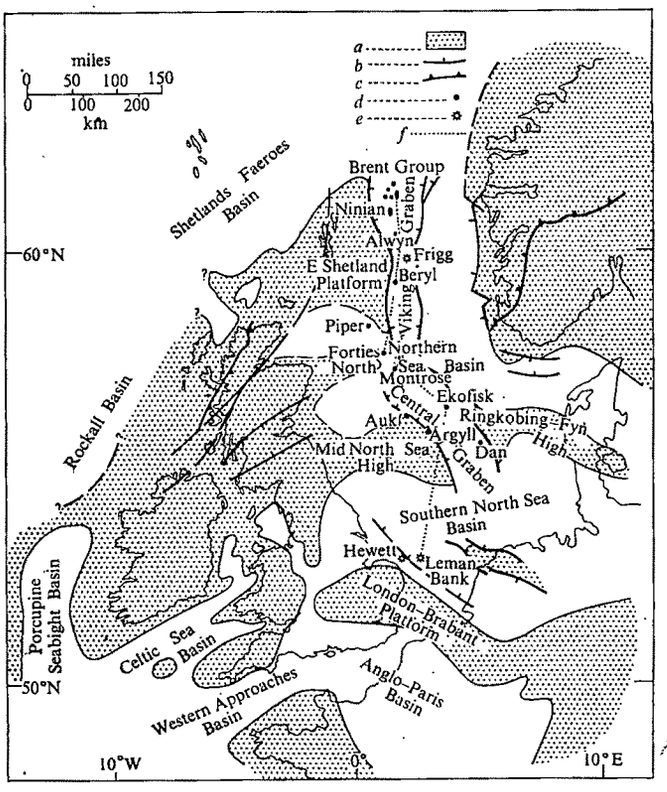

Fig. 1 Sedimentary basins around the British Isles, and the North Sea geological framework since the end of Carboniferous times. *a*, Stable pre-Permian areas; *b*, major faults; *c*, thrust faults; *d*, oil fields; *e*, gas fields; *f*, line of section of Fig. 2.

from the Moray Firth Basin, where Piper Field has been discovered. A further but smaller series of fields seem to be associated with older Palaeozoic rocks where they come into contact with unconformable Cretaceous rocks.

One striking fact revealed by the map of the location of all these oil discoveries, is that they lie within, or close to the edge of, the central, down-faulted area. The fault system is more complex than the simple graben representation (Fig. 1). Tensional and collapse forces developed throughout Middle and Upper Jurassic times after a regional central uplift. The tension was accompanied by volcanicity, mostly of Bathonian age, with at least one centre just to the north of the Forties oilfield. Individual fault blocks remained as positive areas until the end of the Cimmerian movements, after which most of them were covered by Cretaceous sediment. Relative upward movement continued in several instances, however, and some of these structures have uppermost Cretaceous resting on early Mesozoic or even older rocks. This major and complex unconformity is responsible for trapping the oil of the northern area in the underlying structures of Jurassic or earlier rocks. Fortunately, within the Viking graben, the Cretaceous overlying the unconformity is an almost continuous shale and mudstone facies, unlike the ubiquitous chalks of the south. Whether the hydrocarbon source is also in part the Cretaceous shales at the unconformity, or whether it is from indigenous Jurassic shale, is not certain. All of the oils, however, whether from Palaeocene, Cretaceous, Jurassic or earlier reservoirs, have similar properties. The sulphur content is of a low order—

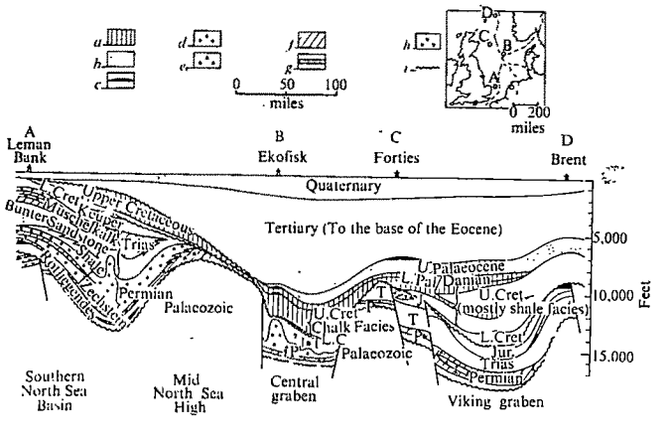

Fig. 2 Generalised and diagrammatic cross section (see Fig. 1) of the North Sea, from the Leman Bank gas field (south) to the Brent oilfield (north). *a*, chalk; *b*, sand or sandstone; *c*, oil or gas field; *d*, halite; *e*, anhydrite; *f*, dolomite; *g*, Coal Measures; *h*, volcanics; *i*, major unconformities. 0.2–0.9% by weight—and asphaltenes are about 0.3–0.6% by weight. Gravities are in the high range (35–44°API, with most restricted to 35–37°API). Wax content is fairly high at 6.5–8.5% by weight, and the trace metals nickel and vanadium are lower than 2 parts per million (p.p.m.). The crudes give good yields of light and middle distillates but are unsuitable as a source of heating oils and bitumen. Gas contents are variable even between adjoining structures. Some are full of wet gas whereas others have oils that are undersaturated, and some reservoirs will therefore require supplementary energy so that the reserves can be recovered.

Estimating the reserves

Our estimates of proved reserves of oil are based largely on published information, including stated offtake plans and

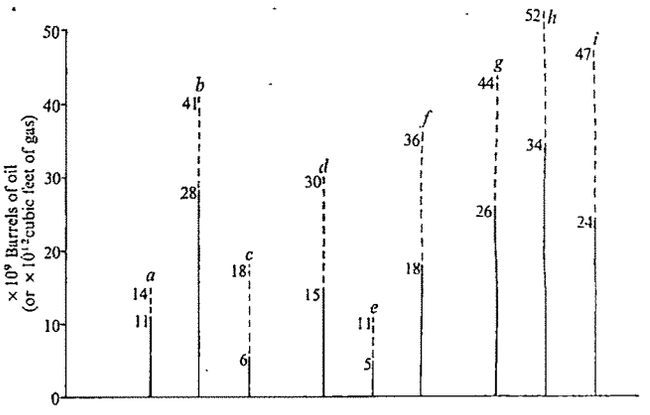

Fig. 3 Recoverable oil and gas reserves in the North Sea. *a–c*, Established reserves; *d–f*, additional reserves; *g–i*, potential ultimate reserves. *a*, Oil; *b* and *c*, non-associated gas, south and north respectively; *d*, oil and gas liquids, *e* and *f*, non-associated gas, south and north respectively; *g*, oil and gas liquids, *h* and *i*, non-associated gas, south and north respectively. Unbroken lines, reserves in UK waters; dashed lines, reserves in the remainder of the North Sea (in both cases: heavy lines, oil; fine lines, gas).

production potential, and they are supplemented from our own borehole and geophysical knowledge of the various structures. Table 1 lists the fields and discoveries, with estimates of recoverable reserves.

Of these discoveries only the main Ekofisk and Dan Fields are currently on production, but all of the named oilfields, with the possible exception of Josephine and Maureen, will probably be producing by some method by 1978. Supposing that the present commercial viability of discoveries depends upon sustained production capabilities of greater than 30,000 barrels of oil a day (or alternatively, 100 million cubic feet of gas a day), and considering that the discoveries of the northern North Sea have taken 100 exploration wells in the UK sector and 80 in the Norwegian sector, then the present success ratio is unusually high, at 1:6 (assuming that each of Ekofisk group of fields is a separate commercial discovery). It is probable that some of the wells were drilled only for stratigraphical information, and some may have been drilled with little

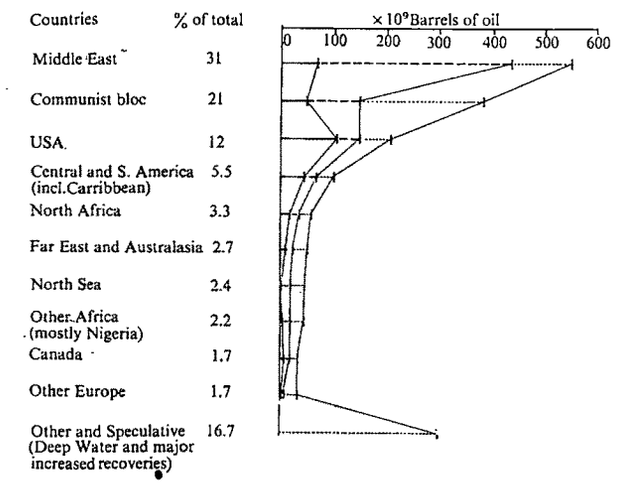

Fig. 4 World oil production, showing remaining reserves and possible future discoveries. Solid lines, produced reserves (300×10^9 barrels); dashed lines, remaining reserves (600×10^9 barrels); dotted lines, possible future discoveries (900×10^9 barrels). The potential ultimate reserves therefore total $1{,}500 \times 10^9$ barrels.

hope of success, only as a commitment to government for obtaining the licence. Some even, were probably drilled in the wrong place because of mistaken concepts of geology or geophysics. I assess that of some 220 prime prospects of present 'plays', about 85 have been explored. The proved reserves resulting from these tests in both Norwegian and UK sectors of the northern North Sea are >14 (for instance, 15)$\times 10^9$ barrels of oil, 18×10^{12} cubic feet of unassociated gas, and >1 (for instance, 2)$\times 10^9$ barrels of condensate (see Table 1 and Fig. 3). Using these statistics the ultimate reserves would seem to be 39×10^9 barrels of oil, 47×10^{12} cubic feet of unassociated gas, and 5×10^9 barrels of condensate (Fig. 3). Most of the major structures in the southern North Sea Basin have been examined, but remaining reserves there, although difficult to find, may amount to 11×10^{12} cubic feet of gas (Fig. 3).

Another, somewhat suspect method of reserves analysis, is based upon the volumes of basin sediment down to the economic basement. Weeks[7] categorised offshore sedimentary basins out to a water depth of 1,000 feet according to favourability for petroleum resources by area. His category A basins totalled 188,000 miles^2, and the average basin thickness was 2 miles, giving a total volume of sediment of 376,000 miles^3 in these basins. Weeks estimated that the A basins contained potential liquid petroleum reserves of 170×10^9 barrels recoverable by primary production methods, and, therefore, that average potential was 448,000 barrels a cubic mile. Similarly, his lower category B basins, of 1,657,000 miles^2, have an average potential of 160,000 barrels a cubic mile. The volume of sediments in the northern North Sea Basin is about 94,000 cubic miles down to economic basement. Assuming that this is a category A basin, there would be an ultimate recovery of 42×10^9 barrels of petroleum liquids. The close similarity of this result with my figure of 44×10^9 barrels of petroleum liquids is comforting, although perhaps fortuitous, as both methods rely on very doubtful criteria.

Our calculations of world oil production, reserves, and future possibilities split into well defined regions, are illustrated in Fig. 4, based on the work of Warman[8]. Since his calculations, more oil has been produced, of course, and a little more has been discovered, but our estimates of future possibilities are slightly less. Now, of the grand total of $1,800\times 10^9$ ultimate barrels, 300×10^9 barrels have already been produced. We believe, therefore, that some $1,500\times 10^9$ barrels could remain, of which 600×10^9 are proved reserves. Again, of the possible $1,500\times 10^9$ barrels, about 800×10^9 barrels are the remaining and possible future reserves of the Middle East and Communist bloc countries. A further 300×10^9 barrels could come from reserves in continental shelf areas in waters deeper than 1,000 feet, or from speculative and unforeseen breakthroughs in, for instance, primary recovery processes. The rest of the world therefore seems to have remaining and possible future reserves of 400×10^9 barrels, of which 140×10^9 have been proved and 260×10^9 are possible. The North Sea, with established reserves of more than 15×10^9 barrels of petroleum liquids and about 30×10^9 potential barrels would seem to rank well with the rest of the world apart from the Middle East and Communist countries (10–11%).

Table 2 League table of oil producing countries in 1973

Country	Average production (millions of barrels a day)
USA	9.2
USSR	8.4
Saudi Arabia	7.6
Iran	5.9
Venezuela	3.4
Kuwait	3.0
Libya	2.2
Nigeria	2.1
Iraq	2.0
Canada	1.8
Abu Dhabi	1.3
Indonesia	1.3
Algeria	1.1
Others (less than 1 million barrels each a day)	6.2
Total	55.5

Future offtake patterns

Turning now to offtake potential to the end of the century, Fig. 5 shows what we believe could be the UK build-up pattern of yearly production, based on the proved reserves of 11×10^9 barrels of oil, and supplemented by the assessed additional reserves of 15×10^9 barrels still to be discovered. Superimposed is the Norwegian picture, built up from the 3×10^9 barrels of established reserves, supplemented by the assessed additional reserves. The patterns are built up from considerations of the time needed to prepare the facilities which are necessary for commercial production from particular fields after their discovery. Furthermore, in normal individual fields it is impractical and undesirable to produce at rates exceeding 10% of remaining reserves per annum. In most cases, if this rate is exceeded the ultimate recovery is decreased. It is, in fact, more realistic to anticipate a reserves production ratio not exceeding 15:1. The graphs of Fig. 5 take these factors into account in the total indicated for each year.

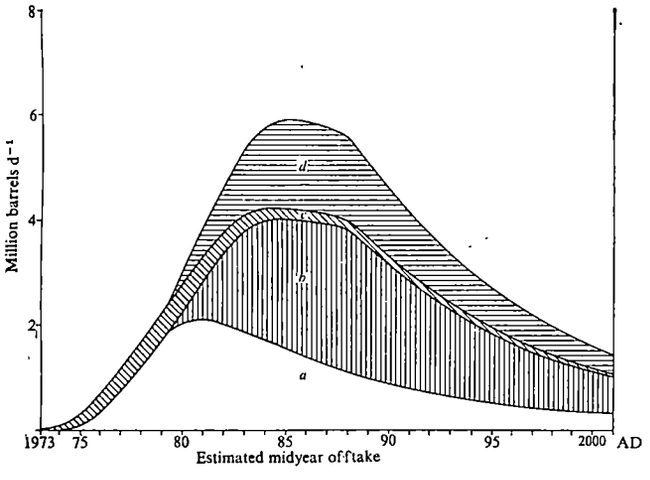

Fig. 5 Possible oil offtake pattern from the North Sea until 2,000 AD. *a*, UK offtake of proven reserves; *b*, UK offtake assuming a maximum discovery rate; *c*, Norwegian offtake of proven reserves; *d*, Norwegian offtake assuming a maximum discovery rate.

The present league table of individual producing countries, including the Middle East giants, is shown in Table 2, which has been derived from average figures for 1973 (ref. 9). Figure 5 shows that the UK will join this league before the end of 1978, and should remain in it until 1988, even if no more oil is discovered. If our estimates of finding the postulated undiscovered reserves are correct, then we shall still be producing about 1 million barrels of oil a day at the turn of the century.

In addition to the amount of oil present in the ground, the offtake pattern also depends upon the will of governments and peoples to extract it. The rate of extraction depends upon the availability of material, financial and labour resources—steel and concrete platforms, drilling units, well completion systems, separators, pipelines laid in deep waters, treatment and storage facilities, and so on—which are necessary to get the oil to the user. The unit cost of development is now running at £1,200 a barrel/day potential and, if inflation continues at the present rate, could escalate at 10% per annum. If the not inconsiderable exploration costs are included, then by 1982 a total expenditure of some £13,000 million will have been necessary to finance the oil development of the North Sea alone if all other resources, and the will, are available[10].

The possible developments on the western shores of the UK–Celtic Sea, Western Approaches, and west of the Shetlands, not to mention further out in the Atlantic, have not been considered here, so a little imagination is needed to increase the various parameters. Until a viable discovery is made I prefer to keep all options open. Reserves may be in proportion to those in the North Sea whereas, on the other hand, the various basins could be virtually empty of hydrocarbons, or contain only gas. Even using the suspect techniques of considering sedimentary volumes, however, the reserves do not seem very high. For instance, the W Shetlands basin out to a water depth of 1,000 feet contains about 13,000 miles^3 of sediment, and if this is a Weeks' category A basin it would contain 5.8×10^9 barrels of petroleum liquids. On the other hand, if it is a Weeks' category B basin it would contain only 2×10^9 barrels. Similarly, the Celtic Sea with about 9,800 miles^3 of sediment could contain 4.4×10^9 or 1.6×10^9 barrels, respectively. Even these theoretical and probably optimistic amounts do not significantly affect world statistics, and only increase my guess at the ultimate reserves of the UK sector by 14–40%. They are included in the category Other Europe in Fig. 4.

In painting this rosy picture of imminent oil availability to the UK, in these days of awareness of a possible world energy shortage, I do not wish to create a complacent and parochial attitude of "I'm all right Jack". I believe that the fortunate accident of nature that has provided these resources on the doorstep of the UK, also provides an opportunity to study and resolve the problems of longer term energy requirements. Nevertheless, even with good husbandry and no increase in requirements, the reserves I have postulated are finite and will have been substantially depleted by the turn of the century.

I should like to thank the Chairman and Board of Directors of British Petroleum for permission to publish this article.

Huge resources needed to exploit shale oil

Colin Norman

Nature, 711 National Press Building, Washington DC, 20004

Although there is plenty of shale oil in the United States, treatment at the surface of the rock that contains the oil would require prohibitive amounts of water. But the alternative, production in situ, *is not yet a well developed technique.*

EARLY this year two oil companies together bid $210 million to lease from the federal government 5,000 acres of arid land in the remote north-west corner of Colorado. At that price, the land is almost as expensive as a prime piece of suburban real estate, and when the bid was announced it surprised not only much of the oil industry but also some of the government officials responsible for leasing it.

The reason why this rugged, largely unspoiled, part of the Rocky Mountains has suddenly become a boom area is simple: it contains more oil than the Middle East. The oil is locked into a band of rock, popularly known as oil shale, which varies from a few feet to about half-a-mile in thickness. According to the United States Department of the Interior, a region of 25,000 square miles which straddles the borders of Colorado, Wyoming and Utah contains about 1.8×10^{12} barrels of shale oil, about a third of which is in deposits rich enough to be exploited.

Already, the promise of this vast petroleum reserve has sparked off gold-rush fever in the small ranch towns in the area—motels are filled to bursting and the population is booming. The federal government, which owns more than 70% of the richest shale lands, is being pressed to speed up its commercial exploitation, and several newspapers—including the London *Times*—have suggested that Rocky Mountain oil shale could be the answer to the energy crisis, not only for the United States but for western Europe as well.

Unfortunately, however, such predictions are grossly over-optimistic, for there are several reasons why the Rocky Mountains will never upstage the Middle East in the international crude oil market, and in any case it will be a long time before shale oil starts flowing through pipelines and heating furnaces. Nevertheless, there is no doubt that shale oil could eventually supply a significant amount of the energy demand of the United States, and there is also no doubt that shale oil production will be accompanied by massive destruction of the environment.

The lease sale this January, which brought the staggering $210 million bid, was the first tentative step in a programme designed to test whether or not the shale fields should be thrown open for commercial development. A total of six such tracts of land have now been put up for lease to private industry—two each in Colorado, Wyoming and Utah—to test various methods of getting shale oil out of the rocks and to give the federal government an opportunity to see what environmental consequences are likely to result from complete commercial exploitation of the shale fields. If the tests prove successful, and if the environmental consequences are deemed 'acceptable', the Department of the Interior, which manages the lands, reckons that up to 1 million barrels of shale oil a day could be flowing out of the Rockies by 1985.

Although that amount is not to be sniffed at, it will represent less than 5% of anticipated demand in 1985 and according to several recent studies it could be close to the physical limit of production capability. The test operations being carried out both on the leased federal lands and on some private land will probably determine the likely potential for oil shale, but much will also depend on the extent to which the federal government becomes involved in the enterprise.

Deposits and extraction

It has long been known that massive deposits of oil are contained in the sedimentary rocks of an area known as the Green River Formation, and in fact some oil was produced from shale even before liquid petroleum was discovered in 1859. But in spite of about thirty years of research and development by the oil industry and the federal government, it has been uneconomic to produce shale oil on a commercial scale for the simple reason that the cost of extracting it from the rocks meant that shale oil could not compete economically with natural petroleum. But the economics were suddenly altered when the price of crude oil began to skyrocket and the Nixon Administration launched its pell-mell drive to make the United States self sufficient in energy.

Shale oil is locked into rock in the form of a solid hydrocarbon called kerogen. To get it out requires the rock to be heated to about 900° F (480° C) and the vapours that boil off to be collected. The result is a viscous, low gravity, moderate sulphur and high nitrogen crude oil which will probably have to be 'upgraded', partially refined, before it is piped to refineries.

Two different approaches to getting oil out of the sedimentary rocks of the Green River Formation have been tested so far, albeit on a modest scale. One approach involves mining the oil-bearing rocks, crushing them and heating them in a surface retort, and the other involves mining or blasting out an underground cavern and heating the shale in place by burning gases. The former method has been more extensively tested, and is reckoned to be closer to commercial application, but the second method, the *in situ* approach, could have significant advantages if it proves feasible on a large scale.

Three chief types of surface retort have been tested, all of which have been operated at the level of 1,000 tons of rock a day. Of these, it is reckoned that a design piloted by the Oil Shale Corporation (TOSCO) is closest to commercial application, but all of them could be scaled up to production levels over the next few years, according to a report prepared recently by the Atomic Energy Commission (AEC) for the Federal Energy Office.

The TOSCO process has as its central feature a rotary kiln into which is fed preheated shale crushed into pieces less than 0.5 inch in diameter. Retorting is carried out by means of externally heated ceramic balls, which are later separated from the spent shale and reheated. The products are drawn off and filtered. According to TOSCO, the process produces an excellent yield, a claim supported by the AEC study, and there should be little trouble in scaling it up to commercial production.

Another process being actively pursued by a number of oil companies is the so-called gas combustion method. This makes use of a vertical retort through which crushed shale moves downwards and gases, fed in at the bottom, move upwards. Air and some additional recycled gases are fed into the retort at a point about one-third of the way from the bottom, which causes the gases to burn. This retorts the shale, and oil vapours and gases, cooled by the incoming shale, emerge from the top. According to the Department of the Interior, "of the numerous retorts studied in the Bureau of Mines program, the gas combustion retort gave the most promising results". Seventeen major oil companies have recently begun to test a modification of the gas combustion process, and according to the AEC study, it will be about three years before the process reaches the stage that the TOSCO process has reached now.

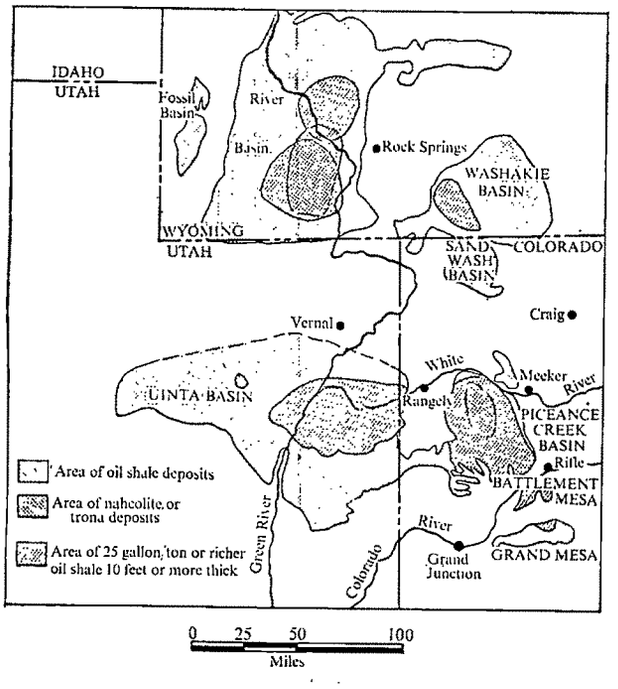

Fig. 1 Oil shale areas in Colorado, Utah and Wyoming.

The third method, the Union Oil Company process, also uses a vertical retort with a countercurrent flow of shale and gas, but in this case the shale is fed in through the bottom. Air is pumped in at the top of the retort and heat is supplied by the combustion of carbonaceous residue which remains on the spent shale. The process was tested in 1957 and 1958 on private land in Colorado, and Union Oil recently announced that it is planning to construct a 50,000-barrel-a-day plant which could go into operation by 1979.

Although the retorts are the only pieces of new technology used in the surface processing of oil shale, the scale of commercial operations will probably be limited by other factors, chief of which is the massive amount of mining that will be required to support even a 1-million-barrel-a-day enterprise.

The shale will be mined either by open pit methods (when it lies close to the surface) or by the room-and-pillar method, but whichever is employed a simple calculation indicates that it would have to be on a truly staggering scale. Assuming that the shale used in the surface retorts contains 30 gallons of oil per ton (one US barrel is 42 gallons), to extract 1 million barrels of shale oil a day with a recovery rate close to 100% would require the mining of about 1.6 million tons of rock. That is an enterprise similar in scale to the entire United States coal industry.

Environmental problems

A direct consequence of this massive mining operation is that there will be an equally massive amount of processed shale to dispose of once the oil has been removed. Since the crushing and retorting operation greatly expands the shale, the spent material cannot be simply fed back into the mines, and so it will be dumped into canyons (and revegetated?).

The spent shale will be bone dry and very dusty, and consequently it will not be easy to get rid of it. It is this aspect of the oil shale operations which most troubles environmental groups, and before the Department of the Interior decides to throw the entire region open to commercial development, it will have to be certain that the spent shale can be dumped and revegetated without undue environmental disruption, however that may be defined.

A second, and ultimately more intractable problem for a large oil shale industry, is the shortage of water in the Green River Formation. According to an environmental impact statement published by the Department of the Interior in August, 1973, a 1-million-barrel-a-day operation would require between 107,000 and 170,000 acre feet of water a year, and municipal development associated with industrialisation of the area would require another 14,000–19,000 acre feet of water. The impact statement suggests that about 340,000 acre feet of water is potentially available for oil shale operations.

This clearly does not give much room for manoeuvre and the AEC study flatly states that "the ultimate rate of production of an oil shale industry may be limited by the amount of water available, although the competition for water should not be severe for a 1-million-barrel-per-day industry". The study adds "a 3 to 5 million-barrel-per-day industry could possibly be established if all the water in the oil shale regions of Colorado, Utah and Wyoming were made available for oil shale development". That would mean, however, that agriculture, minerals processing and other energy industries such as the production of coal gas would have to be severely curtailed.

The chief consumers of water in the oil shale production process are the disposal of spent shale and the upgrading of shale oil so that it can be transported by pipeline. According to the Department of the Interior's impact satement, those two processes between them would use up about half of the water consumed in oil shale production.

Thus if water consumption and mining requirements can be reduced, the potential for oil shale production would be greatly expanded. And that is precisely why the *in situ* process is now being looked at very carefully.

Processing *in situ*

The first thing to be said is that *in situ* technology is not as advanced as surface processing technology, and in spite of some extraordinary claims made by companies involved in *in situ* research and development, there are many problems to be overcome before it can safely be assumed that the technology is ripe for commercialisation.

Nevertheless, one company in particular, Occidental Petroleum and its research arm, Garrett Research and Development Company Inc., has recently carried out a test of an *in situ* process which seems promising. According to Mr Richard D. Ridley, Garrett's manager of oil shale research, the process works like this. First, a room is mined out of the rock beneath and/or above the oil shale. The rock is brought to the surface, where it is either retorted in the conventional manner if it is rich enough in oil shale, or simply dumped and revegetated. The next step is to load explosive charges into deep holes drilled into the walls of the excavated rooms and fire them off so that as the oil shale breaks it will fill the room with tightly packed oil shale rubble.

The final stage is to retort the oil shale in place. This is accomplished by drilling a hole into the top and bottom of the rubble-filled cavern and circulating air through it. Initially, combustion is caused by pumping in natural gas, but eventually carbon left on the shale after it has been retorted provides the fuel. Shale oil runs into a sump at the bottom of the cavern, and it is eventually pumped to the surface.

Occidental has already tested its process on private land in Colorado and it will be conducting a larger test later this year. According to Ridley, if that test is successful, Occidental will be ready to move into commercial production. There are a few problems, however. For one thing, it has been suggested that the *in situ* process will cause subsidence, a criticism which Ridley flatly denies but which has been made by knowledgable oil industry experts in testimony before the House Science and Astronautics Committee. Another problem is that some of the oil shale is overlain by an aquifer which must be kept isolated from the underground retorting process. Again, Ridley claims that this will be no problem but other oil industry officials are not so optimistic.

Speed of exploitation

One indication of the fact that most of the oil industry is not ready to move into *in situ* processing is that of the six tracts of land put up for lease by the federal government, the two which are suitable for *in situ* methods failed even to attract a single bid. The Department of the Interior is now wondering whether to offer them for sale again, but in any case the lack of interest in the two tracts has already led to calls for increased government support for the development of *in situ* technology.

Strong arguments are in fact being raised for the federal government to speed up the exploitation of all the shale lands by immediately leasing more federal land than the six prototype tracts and by providing a variety of financial incentives to the oil industry, such as loans, price guarantees or tax breaks. Moreover, a bill has already been passed by the Senate which would, among other things, establish a joint government–industry corporation to build demonstration oil shale plants; a similar measure is now under discussion in the House of Representatives.

The AEC study recommends that since the potential for *in situ* plants is so high and since the technology is at present not very well advanced, the federal government should concentrate its efforts in this area by assisting industry to establish a plant capable of producing 30,000 to 50,000 barrels of oil a day, to demonstrate the technology on a commercial scale. "If construction began in mid-1975 such a plant could be in operation by mid-1977 and, if successful, could lead to an industry production capability of about 1.8 million barrels per day by 1985," the report says. And the AEC study also suggests that although there is every indication that industry will move by itself to establish commercial-scale surface processing plant, "there are no assurances that significant production by 1980 will result without a major role being played by the government".

Japan and the energy crisis

Takashi Mukaibo

Faculty of Engineering, University of Tokyo, Japan

The central problem facing Japan is how to reduce her growing reliance on imported oil.

FOR many years Japan had a plentiful supply of energy because of her extensive water resources and domestic coal. Towards the end of the 1950s, however, the import of petroleum (a relatively cheap commodity at that time, supplied mainly by countries in the Middle East) increased rapidly to meet the needs of industrial growth. The way in which the proportions of primary energy supplied by various means have changed over the years is shown in Table 1.

Petroleum replaced coal as the chief source of energy in the early 1960s and Japan entered the 'oil era.' Until the recent oil crisis, there was no difficulty in importing cheap oil from abroad and Japan's long coastline, with many good harbours, helped to keep the price relatively low.

The problem in Japan as regards energy supply thus has three major aspects. First, the dependence on oil imports has become so high that the supply is unstable and easily affected by the political and economic situations outside Japan. This is made even worse because more than 90% of the imports came from one region of the world.

Second, the absolute amount of petroleum consumed has become so high that Japan is consuming about 10% of that available to the whole world in spite of the fact that its population is less than 3% of the world total. There is no assurance that Japan will be able to maintain such a large share in the future.

Japan has an area of only about 400,000 km², about 4% that of the United States, and is consuming about one-third of the energy being consumed in the United States. That means that the density of energy (per unit area) is about nine times that of the United States; it also means that the degree of air pollution may be some ten times as great if the measures for preventing pollution are the same.

Japan was faced with a shortage of oil immediately after the declaration of an oil embargo by the Arab countries. Fortunately, the shortage was not too serious as regards quantities but it caused a sharp rise in the cost of oil, which is making itself felt in the cost of all energy sources. The electric power utilities, for example, are proposing to raise the price to the consumer by about 60% on average, which will have serious effects on the whole economy.

Thus Japan has been forced to reconsider the whole system of energy supply, taking the problems mentioned above into account. The first problem to be faced is the saving and the

Table 1 Supply of primary energy in Japan

	1955	1960	1965	1970	1975 (estimated)
Hydroelectric power (%)	21.5	15.3	11.3	8.3	6.6
Coal (%)	49.2	41.5	27.3	21.4	16.3
Petroleum (%)	20.2	37.7	58.4	67.2	72.8
Nuclear power (%)	0	0	0	0.6	2.4
Dependence on imports (%)	24.1	44.3	66.2	76.4	82.4
Total energy* (10^4 kl)	5,125	8,438	14,576	33,100	44,700
Ratio	1	1.65	2.84	6.46	8.72

* Petroleum equivalent, 10,000 kcalorie l^{-1}.

effective use of conventional energy. In considering the measures needed, a detailed analysis of the structure of the consumption of energy in the country has to be made. Tables 2 and 3 show the general structure estimated by the Ministry of International Trade and Industry (MITI) as of 1972.

Details of the measures for saving energy and using it effectively are being developed in industry and research institutions with the support of the government.

The second problem in overcoming the shortage and unstable supply of energy is the utilisation of domestic coal. The coal reserves in Japan are estimated to be about 20×10^9 tons. In the early 1950s, annual production reached 50 million tons a year but the increasing importation of cheap oil has meant that coal production has decreased gradually to the present rate of only 20 million tons a year.

Increasing the use of coal raises two difficulties. First, a huge investment will be necessary to increase the annual production again. The importation of coal is a possibility, but transportation and the requirement of a stable supply may cause problems. The second difficulty is air pollution. As a means of avoiding this, the gasification or liquefaction of coal are being studied. Both are still in the stage of basic research, and the government has started a development programme this year.

The third measure is the exploitation of new energy resources. Leaving aside nuclear energy, which is discussed later, development of various new resources is included in various government projects. There are many active volcanoes in Japan, for example, so there is plenty of potential geothermal energy.

Table 2 Structure of the demand for energy (%)

	Petroleum	Electricity	Others	Total
Manufacturing industries	32.11	15.33	17.41	64.85
Transportation	11.64	0.81	0.95	13.40
Home use	7.96	7.51	3.56	19.03
Others	—	—	—	2.72
Total	52.47	25.13	22.40	100.00

The development of this source of energy has a long history, but because of economic and technical difficulties, only two electricity generating stations are in operation: they have a total capacity of about 30 MW. In order to proceed any further, much developmental study is necessary, for example on deep well technology.

The government has also taken up the use of solar energy as its next energy project. Assuming that 1% of the solar energy falling on Japan is used at an efficiency of 10%, solar energy could provide the wherewithal to generate about 40 million kW of electricity. In Japan there are 2.5 million sets of solar water heating units installed in homes—equivalent to a few hundred thousand kW of electrical heaters. In combination with city gas or electricity, these units may be developed to more efficient devices for home heating and cooling. Other devices such as solar batteries and solar heaters for generating steam are also being examined.

One of the most important aspects of energy in the future is the protection of the environment. To this end, the use of hydrogen as a carrier of energy is under study as well as other means of obtaining clean energy, such as the removal of sulphur and nitrogen oxides from the exhaust gases arising from the combustion of petroleum and other fuels.

The work on the development of solar and geothermal energy, utilisation of coal and the use of hydrogen are all being carried out as part of a project called "Sunshine" which is a government-supported five-year programme. It has just been started and the budget for the fiscal year 1974 is about 2.3×10^9 yen (about $7 million).

Except for solar energy, however, there is a limit to the amount of energy available in each category and it is not high enough to meet the future needs of Japan. The snag with solar energy is that it will be a long time before it can be used in large quantities.

The deduction from all this is that nuclear energy is the only effective substitute for petroleum that is likely to be available this century. In Japan, the current installed capacity of nuclear power plant is some 1,750 MW, and some 15,000 MW more is under construction.

Recently, Mr S. Inaba, a Commissioner of the Japanese Atomic Energy Commission, estimated the structure of energy supply up to 1985 (see Table 4). The data given there do not reflect any official decision, but are estimated by Commissioner Inaba on various assumptions such as stable growth of the economy, the possible development of each category of energy and so on. The energy development programme is under discussion in various government departments and the long term plan for the programme is expected to be formulated this year. In any event, it is considered that nuclear energy will have a key part to play in the future Japanese energy scene.

Table 3 Demand for petroleum classified by end use as of 1971

	%		
Power	17.8		Mainly transportation
Heat	66.1	28.4	Industries
		22.3	Electric power generation
		15.4	Home use and so on
Material	12.8		
Others	3.3		
Total	100.0		

In developing nuclear power, however, there are many serious matters to be considered which are peculiar to Japan. Safety regulations for nuclear plants are very strict because of the high population density and the necessity for designing equipment that is resistant to earthquakes. Radioactivity pollution is a serious hazard especially because of the active off-shore fisheries. There are no parts of the coasts of Japan that are not concerned with fishing industries. It is also difficult to find suitable locations for fuel reprocessing and waste disposal.

Table 4 Estimated future structure of the energy supply in Japan

	1972 (Actual)	1975	1980	1985
Total supply (Petroleum equivalent, 10^6 kl)	366	447	603	800
Annual increase (%)	10.7	6.3	6.2	5.8
Petroleum (10^6 kl)	258	301	393	497
% of total supply	75	72	69	66
Coal (% of total supply)	17	17	15	13
Hydroelectric (% of total supply)	6	5	4	3
Nuclear power (10^6 kW)	1.8	7.4	28	60
Generated energy (kW h)	9.5	49	184	394
% of total supply	1	3	8	13
Others (% of supply)	1	3	4	5

As with other natural resources, Japan is short of indigenous uranium. Therefore, she has to develop nuclear power plants which use uranium as economically as possible. Accordingly, a demonstration power reactor of the heavy water type (165 MWe capacity) is under construction. There is also a fast breeder reactor programme. A liquid metal cooled experimental breeder reactor (50 MW thermal) is under construction and a demonstration fast breeder reactor (300 MWe) is being designed.

Japan has a large ship building industry which is interested in a future programme involving nuclear ships. A nuclear cargo ship of about 8,000 tonnes and with a nuclear reactor of 36 MW thermal has been completed and is awaiting sea trials.

Nuclear fusion is a promising field in the long term. In Japan, research has long been concerned with the basic side, that is, the

study of plasma. Recently, the research has become oriented towards the practical realisation of fusion and more resources are being allocated to it.

The present budget of the government for all the nuclear projects, including fusion, is about 67×10^9 yen (about $230 million) and it is estimated that industry is spending about the same amount of money. About 15% of the governmental budget is devoted to programmes of safety research and development.

Europe in turmoil finds time to discuss energy

Edward Phillips

Nature, 4 Little Essex Street, London WC2R 3LF, UK

Compared with the United States, which imports only a few per cent of its total energy needs, and the Soviet Union, which is a net exporter of energy, Europe is heavily dependent on outside supplies.

IN Europe the nine countries of the economic community are in the process of piecing together an energy policy. Briefly, the plan calls for a reversal of Europe's energy supply position. Instead of 60% of Europe's needs coming from outside and 40% from indigenous sources as at present, the plan says that by 1985 only 40% should be imported and 60% originate within the community.

The reasoning is that the Nine will then have a greater measure of control over the energy received from outside and the price they have to pay, although clearly Europe will continue to be at the mercy of outside suppliers to a considerable extent.

In some ways it is back to the early 1950s when fears of a shortage of energy were instrumental in the establishment of the European Coal and Steel Community and of the ill-fated Euratom organisation. Now after two decades when energy has been plentiful and cheap, energy problems once again loom large in the European communities.

At present there is no ready-made framework for considering energy questions. There has been no common energy policy in the way that there is a common agricultural policy. A good thing some would say (although it is now being argued that the common agricultural policy has not been so inflationary for Britain as was at first feared) but the lack of an energy policy has meant that when a crisis strikes the European countries have no guidelines for action.

In fact each of the three communities in Europe has a finger in the pie. Euratom looks after nuclear energy, coal comes under the European Coal and Steel Community, and the European Economic Community itself (the EEC) deals with oil. The same goes for energy research. Euratom is looking into alternative forms of energy—the so-called hydrogen economy for example—as well as doing nuclear research, the Coal and Steel Community is supporting coal research and the EEC spends money on research into the development of oil.

Apart from the reduction in Europe's reliance on imported energy, the keystones of the proposed plan which was formulated by the European Commission are that oil should in future be regarded less as a fuel for burning and more as a raw material for the chemical industry, and that by 1985 the nine member countries' appetite for energy should be 10% below the present estimates for 1985 consumption, this saving to be brought about by using energy more sensibly than before.

Future mix

The planned distribution of sources of energy is shown in Table 1, with the present distribution for comparison. Taking the energy sources one by one down the table:

- **Coal.** Production within the EEC is to remain virtually steady—179 million tonnes (Mt) of oil equivalent in 1973 and 180 Mt in 1985. There will, however, be a reduction in output from the spent mines of north-east France, Belgium and Holland which will have to be matched by increased exploitation of the British and German coalfields. The rise in the consumption of solid fuel indicated in Table 1 will come from an increase in the utilisation of peat and peat coal mainly from Germany (25 Mt oil equivalent to 40 Mt) and a big increase in coal imports (21 Mt oil equivalent to 35 Mt).
- **Oil.** The main factor here is that the reserves in the North Sea should increase community oil production from a paltry 11 Mt in 1973 to 180 Mt in 1985, with a corresponding drop in imports if the demand for oil can indeed be kept down as shown in Table 1. The burning of oil in power stations and in central heating systems is to be discouraged, but it will have to continue to be burnt in cases where there is no foreseeable substitute—notably in road transport and aviation.
- **Hydraulic and geothermal energy.** The commission believes that there is not much scope for increasing the use of these sources in the community, so they will continue to play only a small part in the energy budget.
- **Natural gas.** An increase in exploitation of the gas beneath Holland and the North Sea will increase internal European production from 113 Mt oil equivalent to 225 Mt in 1985. Even so, imports will also jump from 4 to 150 Mt.
- **Nuclear energy.** A big leap forward in use is envisaged. This may not please the most extreme of the environmentalists.

Taken together these figures mean that energy imports to the Nine will slightly increase from 553 Mt oil equivalent in 1973 to 580 Mt in 1985, while the supply from indigenous sources will go from 369 Mt to 920 Mt, making Europe proportionally less dependent on external factors, but still requiring a considerable input of energy from outside.

At a New York conference on energy supplies, organised by the *Financial Times* and *Oil Daily*, the Director-General for Energy in the European Commission, M. Fernand Spaak, spelt out some implications of the plan: "This strategy requires the community to adopt and to implement a real supply policy for each source of energy within an overall energy supply strategy. Therefore the commission proposes a wide-ranging redefinition of the relationships between the public authorities and the energy industry, in particular those concerned with the transport, refining and distribution of oil and oil products. The objective is to

Table 1 European energy sources for 1985 compared with 1973 (figures in millions of tonnes of oil equivalent)

	1973		1985	
	Mt	%	Mt	%
Solid fuel	225	24.4	255	17
Petroleum	539	58.5	575	38.5
Hydraulic and geothermal	27	2.9	35	2
Natural gas	117	12.7	375	25
Nuclear	14	1.5	260	17.5
Totals	922	100	1,500	100

establish a code of conduct for the industry. The public authorities will monitor the industry's behaviour and will have the means of intervention when necessary".

Savings

The plan also envisages that high prices and a more rational use of energy will lead to a reduction in the annual growth rate of energy consumption by the Nine. Instead of an annual growth rate of 5.1%, predicted last year for the interval 1972–85, the aim is a growth rate of 4%. This makes the Nine's requirements for 1985 to be 1,500 Mt of oil equivalent, the figure used in Table 1, rather than the 1,660 Mt as estimated last year.

It is stressed in Brussels that this reduction does not mean that Europeans are going to go cold in the next ten years. Rather the commission says that by a more rational use of energy it means a reduction of energy input for the same level of output of useful energy. Table 2 shows the hoped-for pattern of consumption in 1985, leading to a total of 1,500 Mt of oil equivalent, compared with consumption if the higher growth rate continues. Figures for 1973 are given for comparison.

Table 2 shows that the European Commission has its eye on the improvement of the design of private dwellings. It

Fig. 1 Mr Fernand Spaak (left): a wide ranging redefinition of the relationships between the public authorities and the energy industry. Mr Henri Simonet (right), Europe's Commissioner for Energy.

has been fashionable for years to say that the thermal design of many houses leaves a lot to be desired, but next to nothing has been done about it.

In the transport sector the savings are to come from increasing the efficiency of existing means of transport and, more vaguely, by better town planning. In industry the commission is hoping for more efficient combustion of fuels and the utilisation of heat that would otherwise go to waste, coupled with a trend towards continuous processes and an end to the planned obsolescence of products.

Finally the plan calls for a European Energy Agency to watch over the security of supplies to Europe by developing existing sources and prospecting for new ones, as well as doing some stockpiling. But the history of the nearest thing Europe has so far had to an energy agency—Euratom—is not a good omen.

So far the plan has been well received. All the same the people in Brussels responsible for formulating it are not counting their chickens before they are hatched. Anything can happen, they say, while Europe is in its present state of shock. The most important precipitating factor has been the British wish to renegotiate its terms of entry into the EEC. With the minority Labour government which is calling for the renegotiation still looking surprisingly strong, this question seems likely to hang fire for many months. Then there is the nature of the joint European relationship with its protector, the United States, to be resolved. Furthermore, this spring there have been unstable political situations in more European countries than is usual at any one time.

Prospects

These factors are undermining confidence in Brussels, where there is apprehension that the energy policy will not be judged on its own merits or demerits and that it may become a pawn in some completely unrelated political squabble, as happened last year when Britain, then with a Conservative government, refused to talk about energy (the question then being the formulation of a joint, short term, way of dealing with the shortages brought about by

Table 2 Energy consumption in 1973 and 1985 (figures in million tonnes of oil equivalent)

	1973	1985 (assuming abundant energy and low prices)	1985 (assuming a more rational use of energy)	Difference
Industry	483	900	850	−5%
Transport	119	215	180	−15%
Private dwellings and so on	317	545	470	−15%
Totals	919	1,660	1,500	−10%

the Arab oil embargo) until Britain got more out of the EEC regional fund.

But so far the talks have gone well—perhaps unexpectedly well. During April the Commissioner for Energy, M. Henri Simonet, presented the plan to the Energy Committee, composed of the senior officials responsible for energy in each of the member states. The committee quickly gave its broad approval (which means that the Conservative line in refusing to talk about energy is not being followed by Labour), but there has been some quibbling about details.

The French and Germans are worried about the problem of marketing the coal once it has been mined if there is a deterioration in its price competitiveness, and the community may have to give aid to coal-mining in exchange for the security of supply endowed by coal.

The British, with their memories of the recent miners' strike and Mr Patrick Jenkins' exhortation that they should clean their teeth in the dark; pointed out that a lot of effort will have to be put into negotiations with the trades unions about rationalisation and wage policy. British

coal mining may not be able to fill the gap left by the closure of the continental mines. And doubts that the increase in production of European natural gas hoped for by the commission could really be achieved were voiced by the Dutch.

A more serious difference of opinion has blown up over the extent to which the activities of the oil companies should be monitored and even, on occasion, interfered with during the implementation of the strategy, as indicated in M. Spaak's speech. France, Italy and Belgium seem to be in favour of a greater degree of monitoring than at present and of the principle of more forceful governmental or community intervention, whereas Britain, Holland and Germany are supporting the oil companies' liberty,, in particular with regard to the companies' pricing policies.

The Energy Committee seems, however, to be unanimous in desiring that the plan to be put to a meeting of the Council of Ministers as soon as possible. With Europe still at loggerheads over other important issues what may happen then is anybody's guess.

Energy problems facing India

Narender K. Sehgal

465-R Model Town, Jullundur 144003, Punjab, India

If India is to avoid the worst effects of the increases in the price of oil she must make better use of her indigenous sources of energy.

INDIA was experiencing acute shortages of energy even before the first of the increases in oil prices had set the stage for a worldwide crisis. These shortages had to do mainly with gaps between demand and supply of coal and electricity, the former aggravated by neglect through increasing dependence on imported petroleum products and the latter by two successive seasons of deficient rains.

Higher oil prices added to India's economic woes (through adverse effects on the balance of payments position) at a time when she was trying to cope with inflation, runaway prices, and sizeable shortfalls in industrial and agricultural production arising from the failure of rains during 1971-72 and 1972–73, and consequent curtailments in power generation (hydroelectric) and imposed cuts in its supply.

A look into India's industrialisation programme (in regard to the technologies employed, the materials used as inputs, the pattern of production and so on) would reveal only a nominal or incidental relationship with the resources available in the country, or the overall needs and interests of the nation or her people as a whole. The tying of agricultural development programmes to the increasing use of oil-based inorganic fertilisers, instead of organic ones, is another case in point.

In general, one is struck by the poor correlation between Indian resources and actual sources in key areas. The area of energy is no exception.

Sources and resources of energy

India gets her 'go' from both commercial and noncommercial (traditional) sources of energy. In the former category are: coal, oil, gas and electricity; in the latter dung, firewood and vegetable wastes.

The present consumption pattern, as far as commercial sources of energy are concerned is: 50% oil (including natural gas), 29% coal and 21% electricity. Electric power generation at the end of 1972–73 was 61% thermal (coal, oil), 37% hydroelectric and 2% atomic (enriched uranium). Similar figures for traditional sources are difficult to arrive at and unavailable. But very rough estimates of 1962–63 figures were made by the first-ever Energy Survey Committee in 1965. They may still be indicative of the relative importance of various traditional sources (Table 1).

Of the noncommercial sources dung is still estimated to be providing nearly 50% of all cooking heat used in the country.

India's resource picture with respect to various sources of energy is as follows:

Coal. It is fairly abundant (except for metallurgical varieties). Known reserves (all types including lignite) are estimated at 83,000 to 100,000 Mt. Present annual demand and production (1973) are 95 and 79 Mt respectively.

Oil. Mineral oil is relatively scarce. The annual production of 7.5 Mt compared to the refinery consumption of 21.0 Mt in 1973 necessitated imports of 16 Mt (including petroleum products).

Electricity. (a) The potential for hydroelectric generation is abundant and has been estimated at 215×10^9 kW h energy a year. Of this, nearly 17% will have been harnessed when schemes underway are commissioned. Major problems are: uncertainties about rainfalls, high capital outlays, and long gestation periods required for completion. (b) The potential for thermal generation is great considering India's abundant coal reserves, provided she can increase its production. Gigantic thermal plants (near coal mines) of capacity up to 2,000 MW could feed a national grid to take power where needed. (c) At present usable nuclear fuel—natural uranium—deposits are very limited. Enrichment of uranium is not yet carried out in the country so fuel for India's only working nuclear power station at Tarapur in Maharashtra has to be imported. India's thorium deposits are among the largest in the world, but breeder reactor technology which is essential for turning available thorium into fissionable fuel, has not yet been developed.

Table 1 India's energy consumption (1962–63)

Commercial fuels			Noncommercial fuels		
Coal	Oil	Hydroelectric power	Dung	Firewood	Vegetable wastes
59.6 Mt	8.5 Mt	11.8 TW h	54.9 Mt	101.6 Mt	31.1 Mt
64.9 Mt c.e.	55.3 Mt c.e.	10.4 Mt c.e.	22.0 Mt c.e.	96.5 Mt c.e.	22.5 Mt c.e.

Mt, million tonnes; TWh, 10^9 kW h; lower figures are coal replacement equivalents for upper figures (Mt c.e., million tonnes coal equivalent).

Cattle dung. This is quite abundant. India has the largest cattle population in the world and milche cattle alone number 67 million.

Wood and vegetable wastes. It is difficult to estimate the extent of consumption of wood and its replacement in the country. But it is feared that poor sections of the rural population, searching for free fuel, may be indiscriminately denuding the landscape at a rate faster than it is being replaced. This needs urgent attention.

Alcohol. It can be obtained in fair amounts through the fermentation of molasses—a by-product of India's sugar industry (among the world's largest). By itself, or mixed with petrol, it could run internal combustion engines in cars and

other vehicles. Actually, that is exactly what was being done in the country in 1947–48 and 1961–62. Agricultural pumpsets can also be run on alcohol with only slight modification to their engines.

Genesis of problems

Most of India's present energy problems are of her own making. The oil crisis which is at the moment threatening to jeopardise the country's entire development effort through its economic consequences is no exception. The problems primarily relate to commercial sources of energy—oil, coal, and electricity.

In less than a decade, starting with the early 1960s, oil has been allowed to push coal into the background and become the energy base of India's economy. This is in spite of the fact that India is known to be richly endowed with coal but quite poor as regards oil.

The emergence over a decade of the present oil-heavy pattern of energy consumption can be traced to untenable assumptions, bad planning and erroneous policies. But it may have been egged on by a number of factors: relatively easy and plentiful availability of oil at favourable prices, until recently; growth of a pattern of production suited to elitist consumption based on imported technologies heavily weighted in favour of oil as a source of energy; characteristic Indian exercise of 'soft options' in importing and implanting as a whole (by not bothering even to effect modifications in imported technologies to the extent of making them suit Indian needs or conditions and reducing or eliminating their continued dependence on imported inputs), and so on.

All this happened despite warnings issued by the first Energy Survey Committee, as far back as 1965, against 'accepting or encouraging, the shift towards oil without adequate caution or consideration.

A 'gobar-gas' (gobar for dung) plant, was devised by the Indian Agricultural Research Institute (IARI) as far back as 1959. The plant can take in all forms of animal excreta and even human night soil. Septic tanks too could support such gas plants. Between 1961 and 1973 only 7,500 such plants were installed, but 20,000 more will be installed in 1974-75 according to a recent government decision.

India's entire rural and agricultural energy demand can be met through installation of such plants throughout the countryside. Along with the gas, organic manure obtained from residual slurry can be used in conjunction with our indigenous output of chemical fertilisers to increase agricultural production.

Questions of interest

A question of interest may be whether or not India will get any 'special deals' from oil-producing countries.

There are two aspects here: price and assured supply. As far as I am aware no oil-producing countries are going to give us special deals involving concessional oil prices anywhere near what they were before the latest Arab–Israeli war. Besides, it would be foolish to expect any of them to agree to do so.

The oil-exporting countries may, however, agree, in bilateral deals, to assure supplies of whatever oil we shall be needing and allow us to pay for them in ways that will not put unbearable pressure on our already difficult foreign exchange position. Some of the ways could be: barter deals; Indian technical assistance and training facilities in various areas for personnel from oil-supplying countries; soft loans on a long term repayment basis for financing our oil purchases and so on. (India has recently signed agreements with Iran and Iraq, but not all the details have been made public.)

Only time will tell how these arrangements, if indeed they are made on the lines indicated, work out in practice. Much will depend on the international situation in the Indian subcontinent. As long as the situation remains normal we shall have little difficulty with our oil arrangements.

Although one hopes for the best, the possible worst cannot be ruled out or ignored altogether. For example, if another conflict were to arise between India and Pakistan, most of our special deals with Arab nations (and Iran) are likely to be among the very first casualties, irrespective of the issues involved in the conflict or the merits of India's position. India must not overlook this aspect.

Fifth Plan and beyond

Unprecedented rises in prices in 1973 and early 1974 have dealt a shattering blow to most of the fundamental assumptions behind the Fifth Plan. While our planners are busy calculating and recalculating things over and over again—every time with higher prices—chances of prices stabilising at home or abroad, around levels assumed in the final Plan draft, would seem remote.

Energy-wise, things are going to be pretty tough during the period of the Fifth Plan. The problem of evolving a new pattern of consumption in which emphasis on oil is reduced to its proper size, as evidenced by its share in our import bill, is likely to keep us fairly occupied in the coming years. The consequent heavier demands on these two sources are bound to aggravate shortages further, unless some of the steps suggested in this article are taken up. Our performance during earlier Plans *vis-a-vis* targets, under far better conditions than at present prevail, gives one little cause for optimism about India's performance in coming years.

What lies beyond the Fifth Plan will, among other things, depend on how we tackle problems in the near future. If we panic over our oil problems and let our penchant for 'soft options' prevail over good sense, as we have often done in the past, the chances of our breaking out of the circle of energy shortages in future will immeasurably recede—notwithstanding some short term gains that may result from such an approach. Soft options here would mean maintaining our level of oil consumption and present oil-heavy energy policy intact by utilising various funds and lines of credit that are being established around the world, entering into unfavourable collaboration agreements with foreign firms for exploration of oil in India and so on.

If on the other hand, we decide to take up the oil challenge and meet it with firm steps and alternatives available to us from within the country, we could turn this crisis to eventual advantage even if no immediate gains result from this approach.

Petroleum products account for about a third of India's entire energy requirement. Last year we spent Rs500 crores (crore=10 million) to import 16 Mt of petroleum and products. For the same quantity we may have to pay Rs1,000 crores this year. This alone will wipe out half of our total export earnings during the year.

To cut consumption, which had become imperative, the Indian government decided to boost prices of all petroleum products. Two instalments of price increases sent petrol prices soaring from Rs1.74 to Rs3.15 a litre and kerosene from Rs0.75 to Rs1.15 a litre—making Indian petrol the most expensive in the world. (Actually the refinery cost per litre of petrol, even after all the increases in crude prices, is less than a rupee. The rest is all excise duty.)

Petrol and kerosene accounted for only about 11% of the total petroleum product consumption of 25 Mt; the rest (89%) was said to have been used essentially as economic inputs by various industries. Thus, industrialists have argued, any substantial cuts in imports of oil and related products would seriously hamper economic development of the country. The Fuel Policy Committee (FPC, set up in 1971 in the Planning Commission to project a long term energy picture for the country) has found, however, that fuel oil is one petroleum product whose consumption (16% of the 25 Mt used in the

country last year) can be drastically reduced without affecting the level of economic activity. Nearly 70% of the industries using fuel oil, according to the FPC, could switch over to coal without any technological difficulty whatsoever.

In the area of agriculture a 'new strategy', launched during the mid-1960s, sought an increase in output almost exclusively through costly inputs like oil-based chemical fertilisers, and diesel-run tractors and pumpsets. Another matchless piece of Indian planning.

Anyone who knows anything about Indian conditions would know that irrigation, organic manures and human manual labour are far more important and crucial inputs for our agriculture. Notwithstanding this, the consumption of chemical fertilisers, estimated at 19.7 lakh tonnes in 1972-73, is intended to be raised to 52 lakh t by the end of the Fifth Plan (lakh=100,000). This would involve imports valued at more than Rs500 crores in 1978-79 (excluding the crude oil costs). Compare this with the paltry Rs9.0 crores allocated for the development of local manurial sources in the centrally sponsored sectors of the Plan.

It cannot be disputed that chemical fertilisers have a useful role to play in Indian agriculture. But the importance and priority being accorded to them, and the total value of resources committed in this direction will be found to be totally unwarranted in any cost-benefit analysis.

Basically, as far as coal and electricity are concerned, it is a case of demand outpacing availability and supply (by 20% in the case of coal and 10% in the case of electric power). Factors like insufficient rains, maldistribution (of power) and problems involving movement of coal (from production sites to consumption sites far away) have aggravated shortages. There have been other reasons too.

Increasing interest in imported oil as a source of energy had serious and far reaching repercussions on coal use and production. From 33 Mt in 1950 coal production had increased to 67.7 Mt in 1965-66 when stagnation set in because of the increasing use of oil. The output of coal increased by only 8 Mt in the next four years and then dropped for two years in a row to 72.06 Mt in 1971-72. Contrast the 1972-73 production of 79 Mt with the Third Plan target of 98.5 Mt a year in 1965-66.

Power-wise, it has been claimed that the country could have had enough power to meet present demand (and even some to spare) had the Fourth Plan targets been achieved during the period of that Plan itself. We missed those targets, by an incredible 50%. Of the 9.3 million kW capacity targeted for commissioning during the Fourth Plan the actual achievement was only about 4.6 million kW.

Apart from a dismal failure to add new generating capacity, our performance with what we already have has been equally poor. For example, plant availability has been low and transmission losses, which one might think ought to have been decreasing, have actually been increasing. From an average of 17% in 1968-69, they were up to 18.8% in 1972-73, reaching 30% in some states.

Thermal stations have experienced difficulties in getting coal in a regular and guaranteed manner. Some older thermal plants are unable to get spares for some of their equipment since plants are outdated and such equipment is no longer manufactured in the countries from which they were imported.

Hydroelectric power generation has its own drawbacks, a major one being the utter uncertainty about rains. For example, for two years in a row now, abnormally deficient rains have necessitated sizeable curtailments in power generation.

Our nuclear power programme is still in its infancy. The only power plant in operation today is the 400 MW Tarapur Atomic Power Station in Maharashtra which was built by an American company on a turnkey basis. An unusually large number of problems encountered in its operation have rendered this first experience not an entirely happy one.

A second nuclear power station near Madras, when commissioned, will provide a far better opportunity for correctly assessing our potential and acquired capabilities in this new technology, since this station is to be a totally indigenous effort. But the true impact of nuclear power in India will be felt only when we have developed and mastered (fast breeder reactor) technology to convert our abundant thorium into fissionable fuel for use in power reactors.

Meeting the challenge

To meet effectively the energy challenge facing us at the moment we must do the following things right away: (a) Cut down oil consumption enough to bring import bill down to a reasonable level; (b) step up power generation and increase outputs of coal and mineral oil not only to meet normal growth in demand but also to neutralise the effects of cutbacks in oil consumption; (c) seriously consider making practical use of the 'total energy utilisation' concept in power stations and industries. (This concept visualises utilisation of all the heat produced by burning fuel. At present, power stations utilise only 30% of the heat to produce electricity and the rest is simply thrown away.) I believe that (a) and (b) could be achieved through three things: coal, alcohol and cattle dung. We can, in a number of cases (of industrial and other use) replace oil with coal without much difficulty. Alcohol, or a mixture of alcohol and petrol, can be used to run automobile and other engines with or without modification. (In the latter case the efficiency of the engine is slightly less.) Cattle dung—at present simply burnt after drying—can be fermented to yield combustible gas (methane) and residual slurry for conversion into organic manure, which is richer in nitrogen, phosphorus and potassium than fresh dung or so-called yard manure. The gas can be used for cooking, lighting and running engines to work pumpsets, tractors and grinders, and even for generating electricity.

Soviet thoughts on energy resources

Vera Rich

London, UK

Nature's Soviet Correspondent shows that the Soviet Union is not being complacent about possible energy problems, large though her resources may be.

ENERGY supplies and resources have always held a prominent place in Soviet planning—Lenin, indeed, defined Communism as "Socialism+Electricity", and the first reaction to the 1973 energy crisis by the Soviet planners was the denial that this could in any way involve them. "The Soviet Union exports annually more than 100 million tonnes

of petroleum and petroleum products . . . The USSR invariably fulfils its contractual obligations and will fulfil them in the future", said the First Deputy Minister of Foreign Trade, Ivan F. Semichastnov, in an interview last January. "Our country is rich in fuel and energy resources . . . In the last 10–12 years the outputs of all forms of fuel have doubled," said the Minister of Power and Electrification Petr S. Neporozhnii in March[2].

Such comments, duly distributed abroad by the *Novosti* agency, would seem at first glance to indicate that a spirit of confidence prevails in the Soviet energy industry, and that the great industrial expansion envisaged under successive five-year plans is comfortably matched by routine and unhurried exploration and exploitation of the new deposits of fossil fuels.

A closer study of the reports, however, indicates a less propitious picture. The Soviet Union will fulfil its contractual obligations to deliver fuel but as regards her further expansion "this is not envisaged at the present moment"[1]. The vast resources of fossil fuel are "extremely nonuniformly distributed", being mainly in the eastern regions of the country with only 10% in the European part of the USSR and the Urals where 80% of Soviet industry is concentrated[2]. The almost daily accounts in *Pravda* of the completion of a section of pipeline or the commissioning of a power station suggest an underlying concern. So, too, do the *Novosti* reports, designed for foreign consumption, which from the beginning of this year have increasingly emphasised the healthy state of the Soviet energy situation. Coverage has varied from straight reports on new power stations, gas fields or pipelines to such details as the use of tea wastes to lubricate oil drills, air-cushion transport of heavy mining gear in the tundra, or the automatic deicing of high voltage power lines in the extreme conditions of Sakhalin Island. Indeed, many of the achievements commended are themselves an indication of the need to exploit all available power resources. Thus on March 5, 1974, *Novosti* reported the selection of a site for a 3,200 MW power station on the river Vakhsh in Tadjikstan (a site where seismic activity reaches magnitude 9, necessitating the placing of the station underground), followed by the description of a new town, Komsomolsk, to be built in the permafrost zone, near a rich deposit of coking coal—the town to house 70,000 inhabitants, the coalmine to produce an estimated 4.5 million tonnes (Mt) a year. In introducing a 'round table' discussion on the prospects of MHD generation of electricity, published in *Nauka i Zhizn'*[3], Academician Vladimir A. Kirillin, Chairman of the State Committee for Science and Technology, commented: "It is sufficient to say that the increase of the efficiency of thermal power stations by even 1% on the scale of our country at the present level of production of electric power would save approximately 3 million tonnes of fuel per annum . . . or . . . would produce an additional 10,000 million kilowatt hours of electrical power."

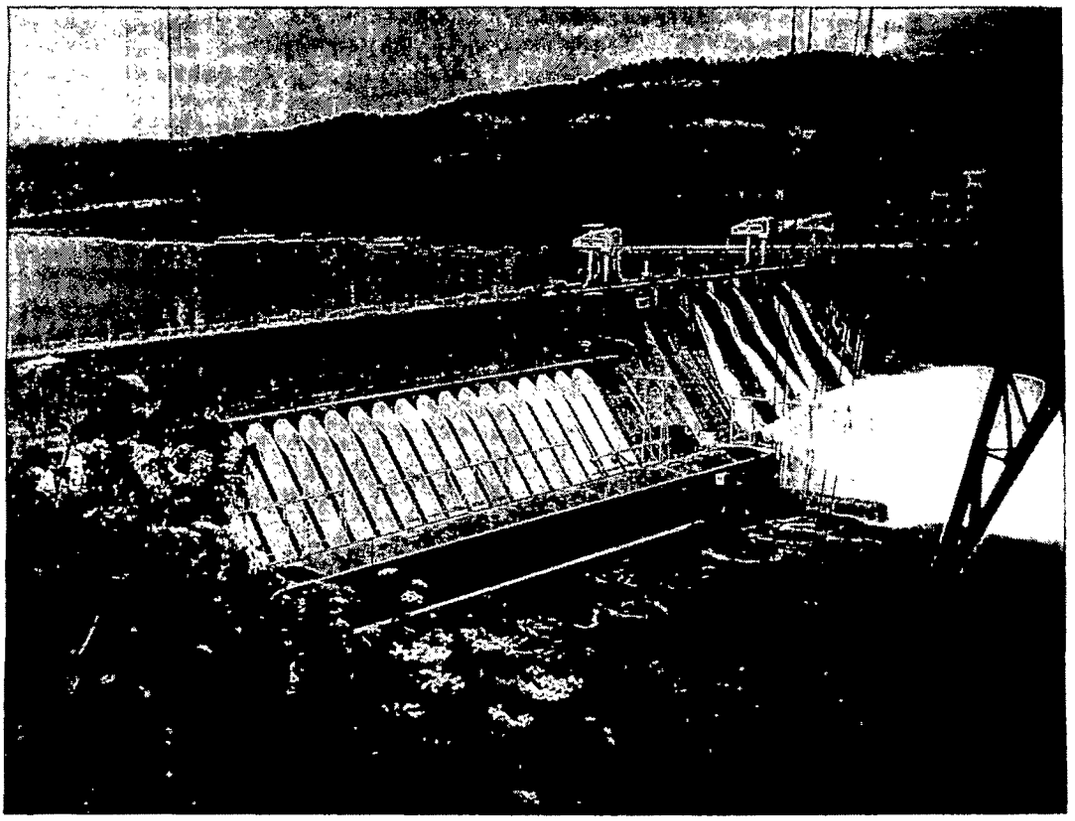

Fig. 1 The Krasnoyarsk hydroelectric power station on the River Yenisei in eastern Siberia.

Future supplies

It would seem, therefore, that in spite of the reassurances of the politicians, considerable thought is being devoted by the Soviet energy experts to the true state of their "inexhaustible' energy supplies. A lecture given by Academician Kirillin, during his recent visit to Britain[4] served only to emphasise this point of view.

At present, he said, more than 80% of the electric power in the USSR is generated by thermal power stations, using chemical fuels, mainly coal. Although the majority of the new power stations to be built will be based on nuclear power, a certain number of conventional power stations will be built in the future. These will almost all be coal fired; in spite of the increased proportion of oil and gas

in the overall fuel output of the Soviet Union (an increase from 51% to 65% in the period 1965–74), the natural resources of coal far exceed those of oil and gas. New gas-fired and oil-fired stations will therefore be built only where coal-fired stations would involve too great a pollution hazard, notably in cities. At present, indeed, there is an increasing emphasis on the importance of the coal industry in the Soviet Union, especially on open-cut mining, which makes the economic efficiency of coal production comparable with that of oil and gas.

(Some recent comparative statistics provided by the *Novosti* agency are of interest: the absolute output of coal in the Soviet Union is increasing by some 100 Mt every five years; the share of open-cut coal in the total coal output, it is estimated, will increase by some 30% in the current year. Considerable attention is being paid to lignite resources, as well as to those of 'black' coal; a recently discovered lignite seam in Byelorussia—conveniently near the industrialised areas of the USSR—is estimated to hold some 50 Mt of fuel, accessible by open-cut mining.)

The use of gas-fired and oil-fired power stations is also indicated, said Academician Kirillin, for peak-hour booster stations. This seems at first glance a somewhat strange admission; according to Minister Neporozhnii[2], the projected supergrid, which will unify the entire power production of the Soviet Union and the Comecon system into a single network, and which should be completed in the next 18 years, is intended, *inter alia*, to obviate the whole peak-hour problem. The considerable time differences between the various parts of the USSR should mean that with the unified supergrid, electricity could be transferred from power stations at local 'off-peak' to consumers in a 'peak' zone, thus saving some 35–40 GW of generating power (that is obviating the need to build power stations to that capacity). But Academician Kirillin seemed less confident. Questioned on the subject, he stated that only some 2 GW could be transmitted by the supergrid as envisaged, and that until superconducting transmission lines become a practical possibility, the need for booster stations will remain—an interesting example of the dichotomy between the claims of the planners and the tasks of the engineer.

Further elaborating on peak and semi-peak boosting, Academician Kirillin indicated that MHD (magnetohydrodynamics) stations are considered as a promising energy source in this field. Generation by MHD is, in fact, one of the specific fields of cooperation between Soviet and United States specialists, which has been developed under the open-ended agreement on technological cooperation of May 1972. A meeting held in Moscow in February and March 1974 resulted in the signing of a protocol on a programme of joint work to design, build and put into operation commercial MHD units. The Soviet team, headed by Aleksandr E. Sheindlin, Director of the High Temperature Institute of the Soviet Academy of Sciences, has already designed and constructed what they describe as an "experimental commercial" MHD generator, the U-25, and on the basis of this work, together with research data, they envisage the commercial operation of MHD stations by the mid 1980s with an efficiency of some 10–15% of that of conventional thermal power stations. Dr Bill Jackson, who signed the protocol on behalf of the United States delegation, observed that the problem of MHD generation is essentially now one of engineering rather than basic research and said that the U-25 generator marks a breakthrough on the engineering side. It should be noted, however, that the Soviet estimates on the efficiency of MHD generation are considered by many western experts to be unduly optimistic.

Nuclear power

Regarding nuclear power stations, the same optimism seems to prevail. In his lecture, Academician Kirillin stated that "most experts believe that extensive construction of nuclear power plants with fast-neutron reactors will not be a practical possibility before 1985"—a somewhat early date, even as a *terminus post quem*. The present generation of Soviet nuclear power stations are mostly of ^{235}U thermal neutron type, either water-moderated water-cooled vessel reactors, or channel graphite-moderated reactors. The latter are of special importance since they can be used as breeders of the plutonium required for the various fast breeder reactors which will form the next generation. One such fast breeder reactor, the BN-600 is already operating (at reduced capacity, because of teething troubles) at Shevchenko on the Caspian Sea, as a source of combined power generation and water desalination. A second BN-600 is under construction. In view of the difficulties which have arisen in the sodium cooling circuits of the Shevchenko reactor[5], it is noteworthy that Academician Kirillin observed that "probably it would be desirable, side by side with the creation of fast-neutron reactors operating with sodium coolant, to speed up the development of this type of reactor with a gas coolant."

Other sources

The other major source of electric power in the Soviet Union is, of course, water power. This has played a considerable part in the opening up and industrialisation of Siberia and the Soviet Far East. This programme is still continuing, with such major prestige projects as the 6 GW Krasnoyarsk power station (the largest hydroelectric plant in the world).

Hydroelectric power plants are now planned in conjunction with other projects—land reclamation, irrigation, and the planning and development of specific industrial centres (for example, the giant aluminium plant at Krasnoyarsk, which consumes one-third of the output of the hydroelectric plant). According to Academician Kirillin, projects are now under discussion for hydroelectric peak booster stations, in which the water is pumped up to a high level by a thermal power station at off-peak time, to be released again at periods of maximum demand. The high costs of such schemes, however, would limit their use only "to areas of favourable terrain".

Regarding such suggestions as the large scale use of solar energy or the Earth's heat (detailed projects for which appear from time to time in the semi-popular scientific press in the Soviet Union[6]) while admitting that their study constitutes an "urgent problem", Academician Kirillin considered that only with "principally new methods" could they yield adequate large-scale results, although on the small scale, for fruit drying or local heating, for example, some useful results have been obtained. Similarly, wind power, tidal power and the like lie, at present, outside the bounds of practical possibilities.

Although further research is needed in these fields, therefore, the main problem before the Soviet power generating industry at present is, in his opinion, two-fold: on the one hand, the more efficient utilisation of conventional thermal power stations—including the use of combined steam-gas turbines, and district heating schemes using the steam from power stations—and, of course, the improvement of anti-pollution measures and on the other, the greater development of nuclear power, including controlled thermonuclear fusion which, he considers, should be available as a source of industrial power generation by the end of the century.

Making energy value for money

W. Short

NIFES Consulting Engineers, NIFES House, Sinderland Road, Broadheath, Altrincham, Cheshire WA14 5HQ, UK

The National Industrial Fuel Efficiency Service Ltd, once a British Government body but now a successful private company, pays close attention to an energy problem that is often ignored.

EVER since the Industrial Revolution, people have tried to improve the use of energy, and countless patents have been issued for devices to economise on the amount of fuel needed to carry out particular work loads. Some of these, such as mechanical stokers and economisers, were invaluable; others were frankly useless, but by high pressure sales methods were sold in large numbers. Even today fuel users must be puzzled at the claims made for some articles which are alleged to save fuel.

Traditionally the industrialist has regarded his energy requirements as a factory service or, at best, as one of the tools of production. His main concern has been the final cost of purchased fuels or electricity per unit of production, insofar as this influenced his ability to compete. Since in most industries this cost has been a relatively small proportion of total production costs his concern has not been of very high priority.

Until recently the continuing availability of the necessary energy sources, in some suitable form, has been taken for granted. True, there have been some short term crises of supply of specific energy sources, but these have been of limited duration and the worst effects have often been mitigated by a temporary or permanent change to other available fuels.

The demand for energy all over the world has continued to increase without interruption since the end of the Second World War, and fortunately this increase was mainly met by the rapid expansion of oil production which, as far as Europe was concerned, meant the Middle East and African countries. The price of fuel oils dropped steadily in the postwar years and was stable for a surprising period in spite of steady rises in the cost of living and of industry's other raw materials. In turn this tended to stabilise other fuel prices, and indeed forced the contraction of the coal industry in the rest of Europe as well as in Britain.

Gas, regarded for all its life as a high price fuel which was only justified where cleanliness, convenience and improved production could justify its costs, dropped suddenly in price to industrial users after 1968 and became a serious competitor, in large scale use, to coal and oil. Unfortunately domestic consumers were not so lucky, as the very high cost of the conversion of their appliances to the use of natural gas together with other inflationary factors, prevented any real reduction in price to them.

Now, in less than a year, the price of oil fuels has rocketed, mainly because the Middle East countries have accelerated demands for participation and increased royalties but also because of the increased costs of such things as transport and refining. Oil fuels have increased roughly three-fold in price to industrial, commercial and domestic consumers alike, and the costs of other fuels have also risen rapidly partly under the influence of 'supply and demand' and also because of large wage increases and investment problems.

Almost at the last moment the industrialist is beginning to take a fresh look at his energy requirements and give this its true place in his priorities. After all, if these energy requirements are not met he will be out of business. In many cases almost for the first time, the industrialist is asking himself the questions:

- What is this industrial energy?
- What is the present situation?
- What should the World, the European Economic Community (EEC) and Britain do about it?
- What can individual companies do?

The answers to some of these questions involve a great deal of speculation. On his answer to the last question could depend the industrialist's competitive position or even his very existence.

We can hope that the recent discoveries in the North Sea will prevent any immediate shortage of supply, but the length of time granted to Britain will depend on the rate of exploitation. An accountant would argue that, if it were technically possible, the best financial recovery on the thousands of millions of pounds being invested would be to extract all the oil and gas in the minimum possible time. This would obviously more than satisfy British demand in these few years and the surplus could be sold to assist balance of payment problems. Such uncontrolled rapid exploitation would in passing be the final blow to the coal industry. There is a better, national argument to extend the period of exploitation, to keep the coal industry at a healthy and relatively steady level of production and so conserve resources to last over a longer period so that other sources of energy can take over as the North Sea's output declines. Nuclear power stations can, and will, be developed to reduce the demands on coal and oil for electricity generation but these need both capital and time to construct and we may well see other new forms of energy production developed such as solar, geothermal, tidal, nuclear fusion and wind power.

All these points so far have been concerned with the supply of fuels and energy, but disregard the effect of price. It is doubtful whether fuels will ever be as cheap again, relative to other costs, as coal and oil have been over the past twenty years. Although it has been argued that actual shortage is unlikely over the next twenty or more years, all fuels will be expensive. Of course it is easy for many companies to pass on the extra cost of fuels as just another of the rises in raw materials prices that cause the cost of their products to increase, and unfortunately many manufacturers seem to be doing just this. While demand exceeds supply, and for many companies this is the situation for a year or so ahead because of the reductions in output caused by the three-day week and cuts in electricity usage of recent memory, such a policy of passing on price increases works. This does not help the consumer, however, and it encourages wage claims.

Also, all our past history of surpluses and shortages indicates that fairly soon many manufacturers will have caught up with their order books and may be chasing customers. There are also services, such as hospitals, local authorities and government, and the domestic consumer, who manufacture no saleable product and so cannot pass on the large increases in fuel and energy costs. These must fall on the

whole community as increases in rates, taxes or personal spending.

Energy conservation can help by minimising the increases in costs of fuels and by reducing the demand so as to extend the period for which the finite resources of conventional fossil fuels will last. The National Industrial Fuel Efficiency Service, NIFES for short, as the most experienced organisation in the field has been able to demonstrate for more than twenty years that large savings can be made. Unfortunately during the era of cheap fuel and energy many companies and authorities have paid little attention to possible savings on a fuel bill which might have been less than 5% of their total running costs, preferring to spend their own staff time, use of outside advisory services and restricted capital resources on other facets of their costs.

A committee which considered fuel efficiency and conservation once said: "The committee reached the conclusion that the gap between fuel requirements and home production would continue to increase and there was the possibility that a critical shortage of fuel would arise. The committee recognised that the nation's economic progress and well-being would depend on fuel and power and that it was vitally necessary to make the most effective use of available supplies". How topical this sounds, and yet these opinions were those of the Ridley Committee of 1952. The wartime Ministry of Fuel and Power had operated a fuel efficiency service and this had continued after the war. Periodic bulletins on various aspects of fuel utilisation, issue of a regular newsletter and provision of a free first-aid advisory service by a staff of around 100 professional engineers and technicians was offered to industrial and commercial fuel users.

The results of these visits were so encouraging that the ministry decided to extend the service so that more detailed surveys of fuel usage could be carried out, both in the boilerhouses context and, more important as it turned out, in the realms of process and space heating. Fees were charged for these detailed surveys and a considerable demand developed from the inception of these 'mobile testing units' in 1948.

After the report of the Ridley Committee, the minister decided to set up a fuel advisory service which would operate outside the Civil Service structure, and so NIFES commenced operations in 1954. In the earlier years much of the running costs came from contributions from the National Coal Board, and the Gas and Electricity Councils, with small additional sums from certain oil companies and the Government of Northern Ireland. These contributions were progressively reduced as NIFES developed its own fee income and in 1969 the government took over responsibility, providing a much reduced and tapering three-year grant on the understanding that the company would become self-supporting.

In the early years, its activities were entirely concerned with fuel problems, using poor quality fuels in many boilers until better fuels became available, carrying out tests on existing boilers, furnaces and processes so that recommendations could be made to improve performance or reduce fuel costs, training boiler operators in correct firing and supervision and giving advice on numerous other fuel problems. Inevitably, as recommendations were made on existing plant and on its possible replacement, many clients expressed the view that the knowledge and experience of NIFES would be of great value to them when new factories or premises were to be constructed or when new plant was to be installed. The company was encouraged by such clients to move into the field of design engineering and advise on all aspects of such capital projects, and for many years now has been handling this field of consulting engineering as part of its activities.

Unfortunately this reduced grant meant that certain services in the education and training fields had to be curtailed, since they had been offered for many years at nominal fees to encourage interest in fuel efficiency and higher productivity. It was found that the demand dropped considerably when fees reflecting the true cost of providing such educational services were asked. One item of which the company is particularly proud is the Boiler Operators' Handbook, which was originally produced as the New Stokers' Manual in 1959 and has been revised and extended in several editions. Nearly 50,000 copies have been sold, and a steady demand still persists for this unique aid to the boiler operator. Nearly 17,000 men throughout industry and the public service have been trained in operation, maintenance and utilisation of plant, and more than 10,000 of these reached the standard of the City and Guild's Boiler Operator's Certificate.

At the end of 1971, the government had decided that NIFES should continue as a private company, but be organised so as to offer all the types of service then being carried out. It is pleasing to record that the staff were so confident of the viability of the company that they were able to agree amongst themselves to raise a share capital and give certain further financial guarantees so that the government agreed to sell the assets and goodwill. As a result the work of NIFES continued without interruption and with the same staff. Modest profits have been made in each of the first two years of private operation and the enginering staff has increased by around 25% since the government handed over ownership.

What is the present company offering? First, there is the enormous amount of experience. Many of the present staff have been successively with the Fuel Efficiency Branch and NIFES and others came from other industrial connections to NIFES many years ago, so that a good proportion of the staff have more than twenty years of experience in fuel, process, heating and allied problems.

The service has always offered to its thousands of clients an impartial advisory and testing service, at first concentrating on fuel and heat problems but very soon expanding into many allied fields. It pioneered the idea of energy measurement and costing and with a unique feedback system of its wealth of experience over the whole diverse range of industrial, government department, hospital and local authority work, it can claim to be able to present a client with the likely operating characteristics of a new plant before it is built. Unfortunately the myth of reliability of fuel suppliers has also been exploded in recent years by strikes and other industrial action and NIFES has helped many companies to install standby electrical supplies or dual-fuel systems, often showing that the cost of standby plant can be turned to profit by using it to avoid peak load charges.

In 1969 an independent survey of the results obtained by NIFES advisory and testing services was carried out and showed that in the first fifteen years of activity total fuel savings were at least 20 million tons of coal equivalent, and these are continuing savings because of alterations in process or production, or the running of existing plants at higher efficiency. The survey concluded that for each man-day spent on investigations and surveys by engineers, the resulting recommendations saved 20 tons of coal or its equivalent a year, much of which would continue to be saved each successive year. Since 1969 many further visits and surveys have been made, and a very conservative appraisal now suggests that some 30 million tons of coal equivalent have now been saved.

If the whole of industry raised its standards of energy utilisation, within practical limitations of scale, to that of the more efficient companies, an annual saving of more than £350 million could readily be made by known and proved techniques and practice which are financially viable even at today's energy costs. This is in fuel costs alone, and at 1974 fuel prices. There would also be inci-

dental savings in many cases because of reduced replacement, maintenance and labour costs, better working conditions and production improvements. Reduced pollution would also result from improved and more efficient fuel usage.

Heat and power surveys carried out over a reasonable sample of industrial groups indicate the potential savings shown in Table 1. The figures do not include the further savings possible by improving thermal insulation standards.

Table 1 Potential fuel savings

Industrial group	Mean saving (%)
Ceramics, brick, glass	15.0
Chemicals	18.0
Iron and steel	20.0
Engineering and metals	18.0
Textiles and leather	15.0
Food, drink and tobacco	15.0
Other manufacturing	21.0

The Thermal Insulation (Industrial Buildings) Act 1959 is one example of legislation which has made a positive contribution to energy conservation during the past 14 years. These standards are inadequate in the light of higher comfort standards, higher fuel costs and energy shortage. They are, in fact, among the lowest in Europe.

The regulations should be brought up to date by:

- Specifying lower standards of heat loss for roofs to reduce losses to half the present permissible figures.
- Extending these standards to cover walls also.
- Applying them to existing buildings, say over a period of seven years, as well as to new buildings.
- Extending the definition of buildings to include commercial and local authority buildings.
- Making some measure of control of space temperatures mandatory.
- Insisting on higher insulation standards for commercial and domestic buildings.

Such a policy would reduce the yearly usage of energy in Britain by at least 6 million tons coal equivalent and with rising fuel costs would be an economically viable proposition in the majority of installations. This takes no account of similar possible high savings on domestic premises.

There is an inbuilt financial incentive in energy savings. An exhaustive NIFES survey in 1965, covering industrial establishments, proved that a total capital investment of £2.5 million in new and modified plant yielded a saving of 300,000 tons coal equivalent a year. The payback period was two years for the sample taken. Although the capital expenditure nowadays would be substantially higher, fuel costs have risen much faster than the cost of energy-using equipment. (As the present high rates of interest have a deterring effect on investment in plant not directly associated with production, there would seem to be a case for reintroducing special investment grants for capital outlay on energy-saving equipment.)

Finally, a few examples where savings have been made. At a Midlands steelworks engaged in the production of stampings, tests were made on seven oil-fired bar heating furnaces. Defects were found on some burners, there was scope for further insulation and the design of the furnaces could be improved, even though the overall performance was as good as the average for this industry. With the cooperation of both operators and management, modifications were made. On a typical furnace, throughput was increased by 14% and oil consumption reduced by 15%, so that furnace performance measured in gallons of oil per ton of throughput improved by 25%.

At a gelatine factory a campaign was undertaken which covered reorganisation of the steam distribution, replacement of steam traps and improvements in recovery of hot water, tests on evaporators, boiling tanks and driers to improve their performance and reuse waste heat in other parts of the process, setting up a record system to examine daily steam usage in departments and reorganisation of the distribution of cooling water. This resulted in a reduction of 29.5% in the amount of steam used per ton of gelatine produced.

Whisky distilleries traditionally operated with stills heated from below by hand-fired furnaces using expensive large coal. For many years NIFES has cooperated with a number of distilleries in a quiet revolution in the whole whisky-making process. Several have converted their stills to steam heating, using highly efficient boilers, and to fullscale waste heat recovery systems to reduce dependence on rivers and streams for cooling water. At these converted plants, fuel savings of 50%, and in some cases slightly more, have been made without any change in the character of the whisky produced.

A company making glazed clay sanitary pipes were experiencing difficulties in drying larger sizes after the moulding process so that they could be fired and glazed in the kilns. After a series of tests modifications were suggested to drying procedures, using high humidity enclosed drying chambers for the first few hours. This reduced the proportion of cracked and unsaleable pipes from 45% to 5%, so that although there was little effect on fuel usage for drying, saleable production was almost doubled.

Nuclear fission as a general source of energy

L. R. Shepherd

OECD High Temperature Reactor Project (Dragon), Winfrith, Dorset, UK

Heat from nuclear reactors can be used for several purposes other than the generation of electricity, for example as a source of heat for chemical processes or for producing 'synthetic' fuels.

THE total world consumption of energy is at present running at an annual rate of about 2×10^{17} kJ most of which is derived from fossil fuel sources. This is approximately 0.2 Q a year where the unit $Q = 10^{18}$ BTU $= 1.054 \times 10^{18}$ kJ is a convenient measure in talking of world energy consumption. The incident solar energy over the surface of the Earth is 5,200 Q a year. Estimated coal reserves would be sufficient to meet this rate of consumption for about 1,000 yr but the calculated

reserves of crude oil and natural gas would be barely enough to satisfy such a demand for 100 yr.

The pattern of utilisation of primary energy sources is, however, not compatible with their availability, oil and natural gas being preferred, to the extent that about two-thirds of our power is now derived from these. This has been a natural consequence of the fact that until recently they have been cheaper and more convenient to use than solid fuels and easier to transport over large distances.

Electricity plays an ever increasing role in the energy mix, but the present world consumption, about 6×10^{12} kW h a year, corresponds to only about 10% of the total primary energy supply. This ratio is certain to increase in the future but the extent to which it may do so is limited by a number of important factors which have to do with the problems of storage, portability and transmission of electricity. Economic considerations generally dictate that electricity should be generated in large centres from which it has to be distributed by overland transmission lines. The range of distribution is limited by the fact that such lines are expensive and losses are high. In this respect it is much more economic to transport energy over large distances in the form of liquid or gaseous fuel.

No large scale method of storing electrical energy at an acceptable cost has yet been developed and this, of course, results in poor utilisation of expensive electricity generating plant, arising from fluctuating load requirements. There is no corresponding problem in the storage of primary energy in the form of oil or gas, of course, and these may be converted locally into the energy form required as the demand arises, including the generation of electricity with relatively inexpensive small plant such as gas turbines.

Except in the case of railways, electricity is relatively useless in transportation because of the problems of devising reasonably light and compact forms of storage. These problems must be regarded as completely insoluble in the cases of aircraft and ships and practically so for fast long distance road transport. The reason is quite fundamental, namely, that only a liquid fuel can meet the requirement of energy carried per unit volume and mass in these cases.

The foregoing considerations suggest that however far we may go in utilising energy in the electrical form, there will always be a requirement for liquid or gaseous primary energy supplies in at least equivalent amounts. This is important in considering the possibility of utilising nuclear energy to replace the dwindling resources of fossil fuels. Up to the present, nuclear fission has been seriously considered only as a source of energy for electrical power generation, but as we have seen this will not meet the total demand for directly usable energy and almost certainly not even the major part of it. It is necessary in the circumstances to consider the ways in which the heat generated by nuclear fission may be more fully utilised to meet the overall needs and not merely to generate electricity to be supplied through the grid.

Scope for nuclear reactors

In looking beyond the use of nuclear reactors exclusively to generate electricity, it is necessary to examine possible applications in the following catagories:

(i) the direct use of waste heat in the thermodynamic cycles involved in generating electricity (low temperature processes);

(ii) the direct utilisation of the heat output of reactors in chemical industrial processes supplemented by electricity production (high temperature processes);

(iii) direct or indirect application of nuclear heat supply to produce synthetic liquid or gaseous fuels (high temperature processes or methods involving intermediate electrical power generation).

The average efficiency of energy conversion from heat into electricity at present is about one-third. In the application of nuclear fission this figure is barely matched by water-cooled systems, because of the low steam inlet temperature in the power cycle, not exceeding 300° C, compared with around 550° C in modern fossil-fuelled stations whose net efficiency may be about 40%. The residual heat, amounting to 60–70% of the total, is wasted and its dissipation often presents embarrassing problems. Considerable attention is now being paid to the utilisation of this reject heat, notably for district heating and possibly for desalination.

The widespread utilisation of the waste energy for district heating is inhibited by the problems of siting central electricity generating stations in appropriate population and industrial centres, where the demand is likely to match the availability of the heat. Social, technical and economic problems are certain to limit the scope for adopting this practice on a large scale, at least in the foreseeable future. Apart from this limitation, however, technical considerations have to be taken into account.

In normal steam cycles the peak temperature of heat rejection is low (~ 50° C) and effective use of the waste heat requires that this should be raised. Reduction in the efficiency of the cycle in producing electricity is acceptable if the reject heat is being utilised, so that it is permissible to raise the back pressure of the steam and the condenser temperature. This merely implies trading electrical energy for useful heat. It is, however, obvious that there is much less scope for doing this in the low temperature cycles of water-cooled reactors than in modern conventional steam cycles whose source temperatures exceed 500° C.

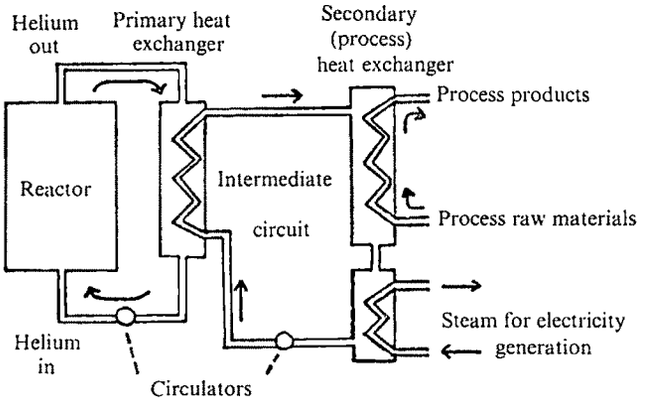

Fig. 1 Direct cycle with utilisation of waste heat. Helium temperatures: 1, ~950° C; 2, ~ 200° C.

The greatest prospects for utilising the reject heat of power conversion undoubtedly lies with the adoption of the high temperature reactor used in direct cycle with a gas turbine. In this system (Fig. 1) the helium acts as the working fluid in the thermodynamic cycle and expands through a turbine which drives the electricity generator. This power cycle, with a turbine inlet temperature of 950° C and an efficiency of conversion to electricity slightly in excess of 40%, would involve heat rejection at a peak temperature around 200° C. Such a high temperature would not only facilitate the utilisation of the waste energy of the cycle for district heating but would introduce possibilities for applying the heat, in a variety of industrial processes, Furthermore, in this system, the potential will exist for increasing eventually both the turbine inlet and the heat rejection temperatures while maintaining the efficiency of the cycle in terms of electrical power output. In this way it would be realistic to consider the application of waste heat in processes requiring heat (possibly as steam) at temperatures up to 250° C or perhaps higher.

Turning to the second category of possible applications of nuclear energy, we have a procedure in which the hot coolant emerging from a reactor is used to provide thermal energy directly in some high temperature industrial process. This is the so-called process heat application of nuclear reactors, which, clearly, is only meaningful if it is associated with the use of the high temperature gas-cooled reactor. So far the technical and

economic feasibility of using reactors to provide heat directly in this manner has only been considered for a limited number of processes, of which the steam reforming of methane and its application in iron ore reduction has received particular attention.

The application of nuclear heat in the steam–methane reforming process would involve using a nuclear reactor to heat helium to a sufficiently high temperature and transferring the heat from the helium to a mixture of methane and steam in an appropriately designed heat exchanger in which these latter gases would be brought as near as possible to the peak helium temperature, in the presence of a catalyst. A range of temperature from 750° to 950° C is estimated to be required for this purpose. The immediate chemical-reaction products in this process are hydrogen, carbon dioxide, carbon monoxide and residual steam and methane, which must be cooled to an intermediate level at which carbon monoxide can be reacted with additional steam to convert it to carbon dioxide. Further cooling to ambient temperature would be required in order to remove the carbon dioxide, residual water vapour and any higher hydrocarbons that might be present, leaving a mixture of hydrogen and surplus methane. Low temperature separation of methane from the hydrogen can leave the latter in a fairly pure state.

If the hydrogen were required to be used in ore reduction it would be reheated in the same plant, in counterflow regenerative heat transfer with the cooling products of the reforming process and further heat from the reactor helium added as necessary for the ore reduction.

The use of hydrogen and nuclear heat to reduce iron ore to sponge iron is an attractive alternative to the present process which uses coke both as a fuel and as a reducing agent in blast furnaces. This arises from the high cost and scarcity of coke in many parts of the world. But natural gas, which is likely to be a rapidly disappearing commodity early in the next century, can hardly be regarded as a satisfactory source of hydrogen in the longer term. Consideration of this brings one into the third and perhaps most important category of nuclear energy applications, that is its use to produce substitutes for the liquid and gaseous fossil fuels. It has been pointed out that these latter currently dominate the primary energy supply situation and that we must expect that the role of liquid and gaseous fuel will not significantly diminish in the future despite considerable increase in the utilisation of central station electricity. Because of this one should think in the future in terms of central energy stations which will export not merely electricity, but also liquid and gaseous fuels and that, in fact, the energy content of the latter may considerably exceed that carried by the former.

The ultimate key to the provision of substitutes for oil and natural gas lies in the intermediate production of hydrogen. In principle, this involves the absorption of energy in water to split it into its constituents. The established method of doing so, of course, is by electrolysis. In going from nuclear heat to hydrogen in this way, however, two efficiency factors are involved, namely, the efficiency of electricity generation and the efficiency of the electrolysis process. The former would be as low as 30% for water-cooled reactors, whereas the latter on the basis of existing technology is 70% at best, implying that the hydrogen product would carry only about 20% of the original thermal energy released. There is scope for eventually improving on this overall efficiency by a factor of two, partly by developments in the electrolysis process and partly by substantially increasing the efficiency of electricity production which should be possible as a result of longer-term developments of the high temperature reactor with direct gas turbine or dual cycles.

To achieve a hydrogen yield corresponding to more than 40% of the input thermal energy, however, would require the adoption of a pyrolysis process, directly utilising the nuclear heat to split the water. Direct thermal decomposition of water is ruled out in so far as it would require a temperature of about 4,000° C to give a high yield of hydrogen by this means. But it is possible to devise sets of chemical reactions involving various reagents whose net effect is to consume water and produce hydrogen while regenerating and recycling the reagents. Many such sets of reactions, involving three or four stages, are now known and can proceed at temperatures lying within the capabilities of the helium-cooled high temperature reactor; they offer the real possibility of producing hydrogen from water in a direct nuclear process heat application.

An alternative route to hydrogen production exists while solid fossil fuels remain in reasonable supply, which is likely to be the case over the next century, namely, the gasification of coal and lignite. The conventional steam–oxygen process of producing hydrogen from coal involves burning some of the coal with the oxygen to produce the heat required for the steam to react with the remaining carbon producing initially hydrogen and carbon monoxide, the latter being subsequently reacted with additional steam to produce carbon dioxide and further hydrogen. Methane is an alternative product obtained by reacting some of the hydrogen with the carbon dioxide, carbon monoxide or the coal itself. The heat used in the endothermic steam–carbon reaction, of course, is transferred internally from the coal burning in the oxygen in the same bed.

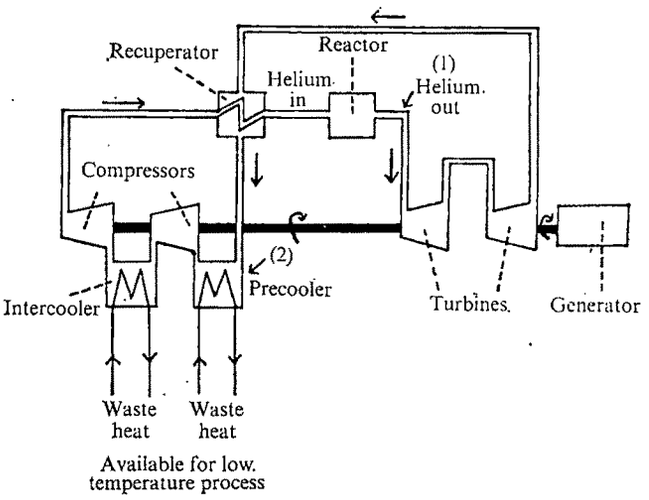

Fig. 2 High temperature process heat application.

The application of nuclear energy would involve externally heating the reaction vessel by means of hot helium instead of the internal combustion of some of the coal. By using external nuclear heating the yield of hydrogen from a given amount of coal could be about 45% higher than that obtained by the conventional combustion method. This important reduction in coal consumption would provide sufficient incentive to adopt nuclear heating which would otherwise have to be justified on questions of cost, with the much higher capital investment of the nuclear plant being weighed against the high cost of the additional coal required in the steam–oxygen process.

Considerable differences of opinion exist in estimating the temperatures required to gasify coal by reacting it with steam. Most experts consider that the peak temperature of the reacting materials would need to exceed 1,000° C for the process to proceed at an economic rate with hard coal and perhaps 900° C in the case of lignite. Lower temperature gasification is possible by reacting the coal with hydrogen to form methane (an exothermic process) and using nuclear heat in the steam–methane reforming process to produce hydrogen, part of

which is then recycled to react with the coal. There is a net production of hydrogen in this process which is the same for a given carbon consumption as in the steam gasification, with the alternative possibility of extracting this net yield in the form of methane. This process would be more attractive than steam gasification if it were not for the fact that a substantial fraction of the coal defies attack by the hydrogen and remains as a char. Success of the process depends consequently on the eventual possibility of being able to convert the char or otherwise use it as a source of carbon or energy.

Technical requirements

The discussion so far in this article has concentrated on the problem of using nuclear energy to produce substitutes for the liquid and gaseous fossil fuels which play such a vital role in supplying our energy requirements. There are many other possibilities for using high temperature heat from nuclear reactors to carry out industrial processes on site and many of these may prove to be commercially attractive. The important fact which emerges in a consideration of these is that they will call for substantially higher helium temperatures than are needed for steam cycle electric power generation. In the latter case a reactor outlet temperature of 750° C is ample to generate steam at say 550° C. If, however, one is to provide heat for chemical processes ranging upwards from about 750° C we have to contemplate the achievement of reactor outlet temperatures of at least 950° C. This would allow for the use of an intermediate heat transfer circuit, with a primary heat exchanger transferring energy from the reactor helium to helium in the intermediate circuit, and a secondary process heat exchanger transferring heat from the intermediate circuit to the reacting materials in the chemical plant. The purpose of the intermediate circuit is to provide a safe isolation between the slightly radioactive primary helium and the hot, chemically active materials in the process plant (Fig. 2).

The feasibility of achieving helium temperatures from the reactor core in the region of 950° C has already been firmly established. In fact, the AVR at Jülich in the German Federal Republic is now operating at that temperature and in the Dragon Reactor Experiment helium emerges from the hottest channels at temperatures in the range 1,000°–1,100° C. Developments in fuel and core materials technology lead to the expectation of mixed helium outlet temperatures perhaps as high as 1,200° C in a few years. The problems of handling gas at such high temperatures elsewhere in the reactor primary circuit, and to a lesser extent in the intermediate circuit, are, however, quite formidable. Thermal insulation will be an aspect presenting many difficulties but undoubtedly the major problems will be associated with the interface heat exchangers, particularly the primary ones. It may be necessary to depart from the more conventional use of metals and go to ceramics or graphite in heat exchangers where the surface temperatures exceed about 1,000° C.

There would also be temperature problems to some extent in the cooler arms of both primary and intermediate circuits of nuclear process heat plants. This is because it is not convenient to have helium above about 350° C in those regions which contain the circulators, control machinery, and so on. The helium temperature drop across the process heat exchanger may be only in the range 200°–400° C so that it will emerge too hot for convenient recirculation. For this reason it would be desirable to take the helium from the high temperature process through a further stage of useful heat removal, most probably in providing the steam to generate electricity so that the plant serves a dual purpose.

Availability of nuclear fuel

It has been assumed here that nuclear fission might be used as a more or less complete energy substitute for fossil fuels. Such an assumption, apart from technical and economic factors, is only valid if the exploitable resources of fissile material are many times greater than those of fossil fuels. The workable reserves of the latter are estimated to be about 200 Q which corresponds to about 2.5 million tonnes (Mt) of fission. In a situation in which sufficient fast breeders exist in sufficient proportion, this quantity of fission could be obtained from about 4 Mt of natural uranium which should be substantially less than that which should be ultimately available from high grade ores at around £10 per kilogram of uranium. Breeder reactors, in fact, could use uranium at a price two orders of magnitude higher, which would make available extensive low grade sources of uranium, notably the 4,000 Mt that exists in solution in the oceans. On this basis, the available fissile energy is incomparably greater than that contained in recoverable fossil fuels.

Unfortunately, the sodium-cooled fast breeder reactor on its own does not fit into the process heat strategy and would only contribute to it if the breeding gain of the fast reactors were sufficiently great to make up the breeding deficits of thermal-neutron high temperature reactors of at least equivalent energy output. (Exclusive use of sodium breeder of course would still permit the generation of hydrogen by the electrolysis route, but the installed capacity of the reactor plant would then be much higher than in the pyrolysis route.) Alternatively, a helium-cooled fast breeder reactor capable of attaining the same output temperatures would need to be developed. This is by no means out of the question.

In the absence of satisfactory fast breeders, however, a nuclear process heat strategy on a level of at least 1 Q per year could be supported with thorium cycle high temperature reactors operating in a thermal-neutral near breeding regime. These might require about 300,000 t of natural uranium and 15,000 t of thorium to yield 1 Q of heat and it would be economically feasible to use uranium from sea water in this application. To all intents and purposes this would constitute an indefinite supply of energy.

Wave power

S. H. Salter

Bionics Research Laboratory, University of Edinburgh, Edinburgh EH1 2QL, UK

Solar energy is one form of income on which we can afford to live. Here is another proposal: the use of power from the waves at sea.

THE amount of power in a wave train can be estimated by calculating the change of potential energy as the water in a wave above sea level falls into the trough in front of the wave (Fig. 1). If the sea water has a density ρ, and the width of the wave front is W, then the mass of water in the half sinusoud above sea

level is

$$W\rho(\lambda/2)\,(H_{tc}/2\sqrt{2})$$

using the notation defined in Fig. 1. The height of the centre of gravity above sea level is

$$H_{tc}/2 \times 2\sqrt{2}$$

falling to an equal distance below. In such a situation the change of potential energy would be

$$gW\rho\,(\lambda/2)\,(H_{tc}/2\sqrt{2})^2 = W\rho g H_{tc}^2/16$$

It is known that the frequency of gravity waves in deep water is

$$(1/\lambda)\,(g\lambda/2\pi)^{1/2}$$

and, therefore, the rate of transfer of potential energy, or the power, is

$$W\rho g H_{tc}^2\,(g\lambda)^{1/2}/16\sqrt{2\pi} \qquad (1)$$

Progressive waves transport energy across the sea, and it is valid to say that the rate of transport of energy across some line is power. Power density can be specified conveniently in kW m^{-1} of frontage.

The Institute of Oceanographic Sciences publish valuable data on waves using instruments developed by Tucker and Pierce[1]. Draper and Squire[2] have analysed observations from Station India (59°N 19°W) which is characteristic of the western approaches to the Hebrides. The amount of power is prodigious. The relationships between various wave parameters have been explained[3]. For waves at sea it is more convenient to measure the period, T, than the wavelength, λ. Oceanographers like to use a height measurement, H_s, the significant wave height, defined as the average height of the highest third of the waves. In order to extend this discussion to include random waves at sea, H_{tc} of equation (1) can be converted to H_s using the root mean square displacement, D_{rms} : in a sinusoidal train

$$H_{tc} = 2\sqrt{(2)}D_{rms}$$
$$H_s = 4D_{rms} \text{ (ref. 3)}$$
$$\therefore H_{tc}^2 = H_s^2/2$$

Wavelength, λ, can be converted to period, T:

$$\lambda = T^2 g/2\pi$$
$$\therefore \text{Power} = W\rho g^2 T H_s^2/64\pi \qquad (2)$$

The power which could be extracted can be predicted (Fig. 2 and ref. 2). Computer programs can apply equation (2) to each cell of Fig. 2. The average power over a whole year is 77 kW m^{-1} of frontage. Model tests suggest that the fraction of energy which may be extracted depends on the depth of the installation.

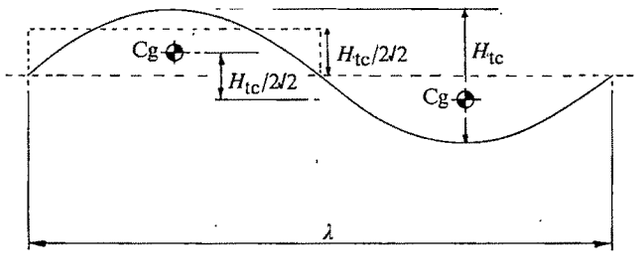

Fig. 1 Part of a progressive train of sinusoidal gravity waves in deep water. λ, wavelength; H_{tc}, trough to crest height; Cg, centre of gravity.

Above a depth d, this fraction is $1-\exp(-8\pi^2 d/T^2 g)$. New arrays can be drawn up for different depths, with each cell containing the contribution down to that depth. Unfortunately, some of the power comes in uncomfortably large amounts. A practical installation might need to be underdriven or submerged during the most severe weather. Further arrays for different power limits can be constructed with the contributions of high power cells reduced to some allowable maximum. Table 1 shows the results for combined depth and power limit reductions from three sea areas, and Fig. 3 shows the relationship between power density and wave period for the three observing stations.

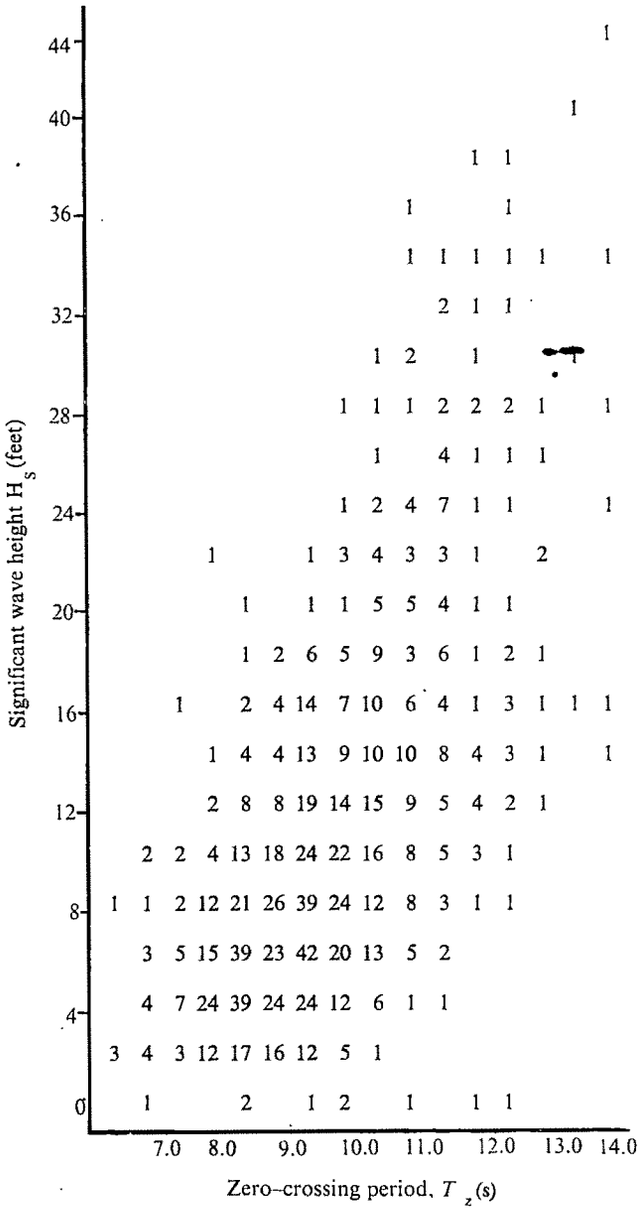

Fig. 2 Scatter diagram for whole year observations at Station India reproduced from ref. 2, showing the number of occurrences, in parts per thousand, of waves of a particular height and period.

Design problems

A search of British Patents shows about a hundred proposals of varying feasibility for extracting wave energy (see refs. 4 and 5). There was a spate of them after the First World War. Flaps, floats, ramps, converging channels and liquid pistons are all advocated, and much ingenuity is expended in accommodating tidal rise and fall. Model tests on some proposals, however, show poor efficiency. More recently, though, the successful operation of equipment at low power levels for buoy and lighthouse use, has been described. (Y. Masuda, and T. Yoshida, preprints.)

The essential problem is finding a method to convert dispersed, random, alternating forces into concentrated, direct force, using a mechanism which is efficient at low levels and yet robust enough to withstand the worst conditions. I believe that rigid connections to the sea bed are not possible on a large scale, and that the installation must be freely floating out at sea. As much of the equipment as possible should be below the surface. Concentrations of stress must be avoided, and power should be extracted smoothly.

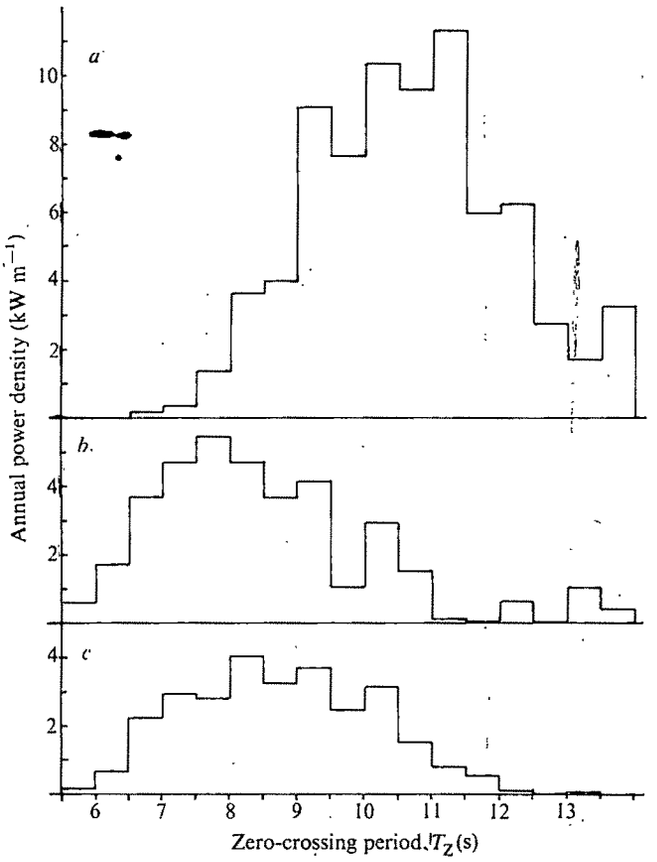

Fig. 3 Distribution of annual power density with period: *a*, Station India; *b*, MV Famita; *c*, Sevenstones.

Moving parts, are generally troublesome, but designs without them can only produce large volumes at low pressure differences, and need some kind of transformer for efficient conversion. I must, therefore, reluctantly accept the conclusion that the use of moving parts is unavoidable. I think that it is best to use rotating elements, and to protect mating surfaces from the sea. It will be difficult to gather in power from many small units moving independently, and so there should be a common framework for a number of them. As waves transmit energy to one another with very high efficiency, the water must be allowed to move in its usual circular pattern.

The first step is to get away from the idea of an object bobbing up and down, although, of course, it is this aspect of wave motion which is most apparent. Use of the to and fro movement would be much more rewarding. The energy passing through a vertical window is concentrated close to the surface and the water movements at all depths are of the same phase. I have tested a simple vertical vane pivoted about a horizontal axis along its bottom edge one eighth of a wavelength down. It works over a reasonable range of wavelengths and it shows an efficiency of about 40% when driving an electronic dynamometer. Roughly 25% of the energy is transmitted onwards, and about 20% is transmitted back to the source. It would, however, be much more efficient if, somehow, it could be designed so that it did not displace water astern and so that the amount of water displaced at any depth corresponded to the amplitudes of water movements at that depth. But is a vane of this kind possible?

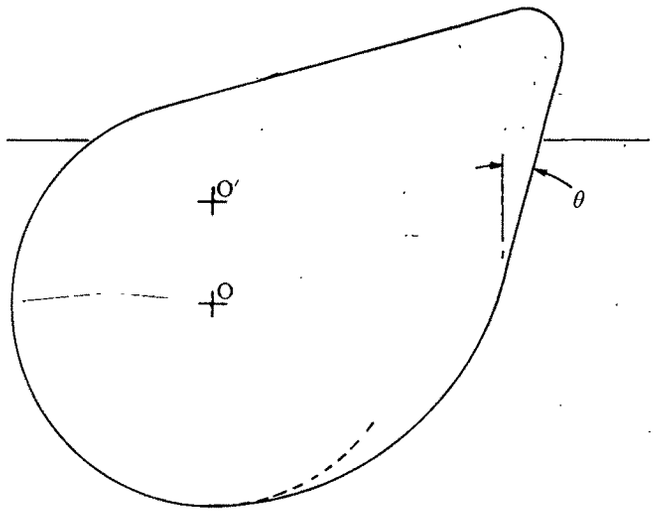

Fig. 4 An efficient vane shape designed to rotate about O. Waves come from the right.

The design

Consider the shape shown in section in Fig. 4. It rotates about its centre, O, and absorbs power from waves coming from the right. Its stern is a half cylinder centred at O, but from the bottom point it grows into a surface which is another cylinder centred about O′. This shape continues until it reaches an angle θ, to the vertical, at which point it develops into a tangent, which is continued above the surface. In my first model, O′ is one half radius above O, and θ = 15°. The efficiency for wavelengths of about eight times the diameter of the small cylinder

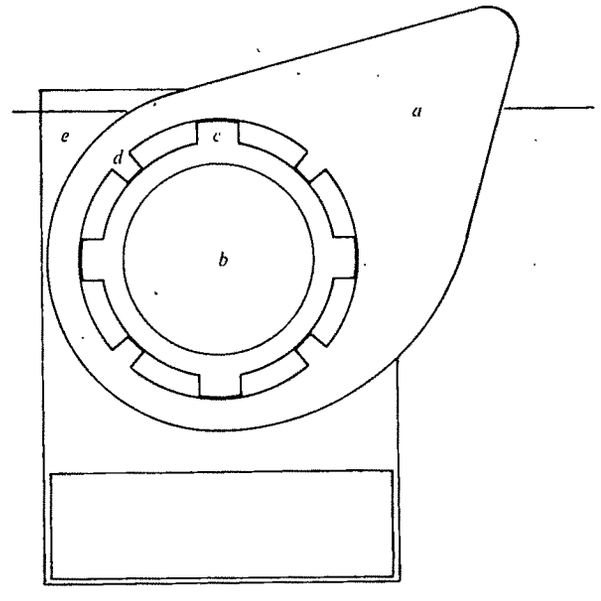

Fig. 5 A vertical section through vane and spline pump. *a*, vane; *b*, a hollow cylindrical member; *c*, paraxial ridges; *d*, inward facing ridges on the vane; *e*, vertical fin between this vane and the next. For the North Atlantic the diameter of the cylindrical portion will be between 10 and 20 m.

is over 80%. I intend to test the theory that a good vane should be able to extract nearly all of the power contained in the band of water above its depth of immersion.

When the vane moves there is no change in the displacement of the water behind it and the changing displacements in front of it rise from zero at the bottom of the cylinders to amounts close to those in the approaching wave. This means that the shape meets the necessary requirements. It is, so far, the most successful of the likely shapes that I have been testing in a wave tank. The models are coupled to a dynamometer consisting of two moving coils in a magnetic field. Velocity signals from one coil are amplified and sent to the other so as to oppose movement. Velocity and force signals are multiplied to indicate power absorbed by the vane and are compared with wave height measurements. This electronic simulation is very convenient for laboratory tests.

In full scale equipment at sea, the random rotations of a vane will produce unidirectional pulses of water flow through a special pump (Figs 5 and 6). The water is deoxygenated and decarbonated, and recirculates within the system. A vane is supported on, and rotates about a hollow cylindrical member with paraxial ridges on its surface. The outer faces of the ridges are supplied with high pressure water from an auxiliary pump, and they form hydrostatic bearings[6]. Between them there are inward facing ridges from the vane. The pair fit as a spline with close radial, but very loose circumferential clearance. The

spaces between the inward and outward facing ridges form four double acting pumps with nonreturn Macleod valves[7] in the walls of the ridges on the cylinder (Fig. 5). These valves were originally developed for use with blood pumps. They consist of an elliptical butterfly plate across a conical passage. The centre of rotation does not pass through the centre of pressure and so there is a strong closing action. In the open state they offer minimum occlusion and are the most efficient nonreturn valves that I know of. The working surfaces of the pumps are faced with ceramic, and are ground.

A common back bone for about 40 vanes is provided by the cylindrical member. An outer tube contains manifolds connecting the spline pumps to a common turbine at the centre of the structure. The high pressure manifolds (400 pound inch^{-2}) are made from 1 m diameter pipes (Fig. 6). Inside this ring of pipes is a large tube which forms the low pressure manifold and which returns water from the turbine to the pumps. The interstices between the pipes and the inner and outer tubes are filled with a mixture of lightweight concrete, glass fibre and resin. The ends of the pipes and tubes are swaged to allow a clamped connection of each length to the vertical fins fitted between vanes (Fig. 5). These fins house trim tanks, pressure smoothing accumulators, and the pipe work which couples each pump to the manifolds. At the bottom of the fins concrete ballast keeps the centre of gravity well below the metacentre.

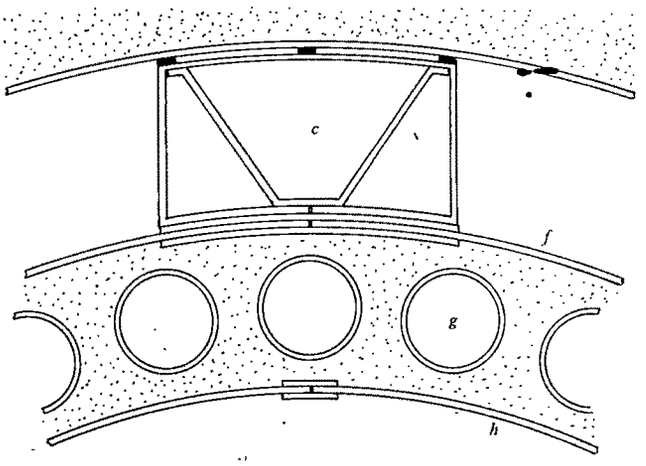

Fig. 6 Enlarged section of the spline pump, showing one ridge and the manifolds. *c*, Paraxial ridge shown in Fig. 5; *f*, outer tube containing manifolds; *g*, pipes of 1 m diameter; *h*, large tube, forming the low pressure manifold.

A crucial problem facing the designer of wave power machinery is the provision of a steady reference against which his waves can act. Many approaches use connection to the land but this design would operate out at sea. A stable reference can, however, be supplied by using a structure 0.5–1 km long. A short machine would pitch and heave and develop little force between vane and backbone. As the length is increased the installation samples a wider range of wave phases and becomes more and more steady. Stability is obtained from the inertia of the ballast weight, from the drag of the deeper parts in quieter water, and from the coupling of the machine to waves of opposing phase. The only drawback to using very great lengths is that the stress which can be developed by the worst conceivable wave rises with the square of the length. The largest predicted wave in 50 years in the North Atlantic would have a trough-to-crest height of 34 m and a period of 16.5 s. The surface particle velocity would be 6.5 m s^{-1} with a resulting stagnation pressure of 21,000 N m^{-2}. The shear forces and torsions which result from such monstrous waves would not be the most serious problem. It is the bending moments which are critical, and which set limits to the lengths which can be used.

Energy storage

In common with solar, nuclear, and wind power, wave power comes at times not necessarily convenient to the user. Although its seasonal availability roughly matches demand, the problems of storage and distribution require careful attention, and will have to be taken into account in the overall planning. Electrolytic production of hydrogen from sea water looks promising in this respect.

The installations could be self propelled. They could move in

line ahead, a low drag condition, out into the Atlantic, turn abreast to the waves, and be slowly driven back by wind and wave thrust, storing hydrogen on the way. Most of the hydrogen could be discharged at a shore terminal, leaving enough to get out to sea again. This mobility gives many advantages, and obviates the mooring problem.

Wave power is clean, safe, permanent and uses relatively simple and well known technology. It is likely to receive plenty of support after a bad nuclear accident but it would be prudent to have the basic research done now[8]. We are particularly fortunate in our resources of wave energy. The approaches to the Hebrides are probably the best site in the world. A few hundred kilometres of installation could meet the total present electrical energy requirements of the UK.

I would like to thank the University of Edinburgh and the Nuffield Foundation who supplied my workshop facilities, the National Institute of Oceanography, and my colleagues Drs O. P. Buneman, C. A. Greated, D. Mollison, and J. W. Ponton, for their help and criticism, and Sheikh Ahmed Zahi Yamani and OPEC for their continuing encouragement.

Prospects for hydrogen as an energy resource

J. K. Dawson

Atomic Energy Research Establishment, Harwell, UK

Storing energy in the form of hydrogen is an attractive possibility to provide fuel for transport and the reduction of iron ore. The main obstacle is the expense of the electricity needed to synthesise hydrogen.

THE recent restrictions placed by the producing nations on the global supply of oil, and the growing realisation that world demand for oil and natural gas is increasing at a rate faster than the discovery of new resources, have focused attention on the need for alternative energy resources. There is no immediate crisis in terms of proven oil and gas reserves, but development towards alternatives should start soon if the new technology is to be widely available when it is needed. As an indication of the time scale required for the introduction of a new energy resource it is worth pointing out that 18 years after the commissioning of the first Calder Hall reactor, nuclear power has still not achieved more than 10% penetration of the market for electricity production in the United Kingdom.

Forecast of the time when the rate of production of oil will begin to decline vary over a considerable period, and might be as early as the mid-1980s if historic trends continue: it is assumed here that the decline will certainly be evident by the end of the century. As we approach that time two primary energy sources are likely to assume over-riding importance: coal and nuclear fission. But synthetic secondary fuels are likely to be needed for special purposes and hydrogen could be one of these. Hydrogen is best regarded as a potentially attractive means of storing and transporting energy which can be provided from a variety of primary sources: it is therefore more analogous to electricity than to oil, although some of its most rewarding applications may be as a substitute for oil products. The hydrogen would be produced from water and in this process more energy is expended than is recovered in burning the hydrogen subsequently; this point will, however, assume decreasing importance as the production of hydrogen moves progressively towards dependence on renewable energy resources. Hydrogen attained industrial importance a few decades ago when coal provided the primary energy for water splitting; now it is produced in larger quantities from natural gas and oil: if it is to achieve the even more widespread use implied by the 'hydrogen economy' then it will have to be based on the energy input from nuclear fission reactors and subsequently there could be a gradual transition to nuclear fusion and solar energy resources.

Much has been written on the subject of hydrogen over the past few years, culminating in the nearly 100 papers at a recent conference devoted exclusively to the subject (see ref. 1). It is not possible to review all of this work here; I shall attempt rather to take a realistic view of the overall prospects and of some of the problems to be overcome.

Markets for hydrogen

As oil becomes a scarce resource and nuclear energy takes over, in principle all major energy users except air transport could be satisfied by the increased availability of relatively cheap electricity—much has been written on the advent of the all-electric economy. This would also require however, the development of major new technology, of which the long range electric road vehicle is perhaps an outstanding example. It is possible that when the costs of transmission and storage are added to the cost of production, under some circumstances hydrogen may become competitive with electricity for many uses. This possibility of interchange and substitution between several energy sources renders the whole subject very complex: the forecaster finds it fascinating and yet extremely hazardous.

One of the largest new uses for hydrogen could be as a fuel for road transport: in the United Kingdom this might ultimately amount to a requirement of several million tons per year. The competition will however be strong among several candidate fuel supplies:

- allocate oil to road transport as a priority item
- electricity, based on advanced batteries for energy storage on the vehicle
- liquified methane (natural or substitute)
- methanol
- hydrogen

Each of these possibilities has its advocates and, apart from the first item, each has a considerable range of development problems to be overcome. Perhaps a mixture of several solutions is the most likely outcome, with each fuel taking a particular share of the total market.

Practical experience has shown that the use of hydrogen requires little alteration to the internal combustion engine on

which so much development effort has already been lavished, and the environmental pollution from hydrogen would be much less than from petrol. It is feasible for the same vehicle to be engineered to be able to switch as required between a hydrogen and a hydrocarbon fuel supply. Increasing attention is now being given to devising the best means of storage of hydrogen on road vehicles. Storage as gas would be totally uneconomic but on present evidence there is no clear choice between cryogenic techniques and storage in metal hydrides. It is possible that hydrides will prove to have over-riding safety advantages. The most promising hydride system proposed so far is based on iron-titanium alloys, which are capable of absorbing and desorbing hydrogen at near ambient temperatures. There is much useful basic work to be done to arrive at the optimum hydride composition to meet criteria of high hydrogen density, low overall mass, avoidance of high operating temperatures, and the ability to withstand multiple recycles.

Economic forces will play a large part in determining whether hydrogen really can compete. There is a growing number of attempts in the literature to forecast the relative costs of the various fuels up to the end of the century, and as would be expected they cover a considerable range. For the United Kingdom in the late 1990s, the ranges in Table 1 summarise the production cost estimates. North American cost predictions tend to be a little lower, mainly in the range 100–140 (see ref. 2 for a useful comparative summary) pence per GJ for hydrogen by electrolysis. It is apparent from these figures that there would be a chance for hydrogen to become competitive with petrol towards the end of the century if the more optimistic rather than pessimistic assumptions prevail. Synthetic petrol from coal seems somewhat more promising but, as pointed out by G. V. Day at a conference on energy, Europe and the 1980s at the Institute of Electrical Engineers, London, May 1974, environmental restrictions and the availability of labour may restrict coal output to below the level required for the large-scale synthesis of petrol in addition to coal's more traditional role in electricity production.

There is potentially a much larger market for hydrogen as a substitute for natural gas for the majority of domestic and industrial purposes (possibly as high as 12×10^6 tons yr^{-1} in the United Kingdom) in which its energy content rather than chemical properties are important. As long as supplies remain available from the North Sea it will perhaps be impossible for hydrogen to compete on cost grounds (a factor of two to three lower than the cost quoted in Table 1 would be needed). But again towards the end of the century, these supplies may well become insufficient and hydrogen could present competition to replacement by substitute natural gas (SNG) from coal. Though at first sight it might seem possible to utilise the existing gas distribution system to distribute hydrogen, there may be very substantial problems in technology and in the logistics of a gradual changeover. Although this market is very large, therefore, it might not prove possible to penetrate it, except in the case of communities isolated from the national gas grid system. Detailed assessment studies of this aspect of the hydrogen economy are required.

There are specialised uses for hydrogen which may account for somewhat smaller demands, but which nevertheless would be large by current standards of production. One of these is the direct reduction of iron ore for steel making. This idea has been around for a long time and is currently attracting more attention because of problems created by the diminishing supply of metallurgical coke. In the United Kingdom the hydrogen demand could rise to the order of 10^6 tons yr^{-1} for this purpose. Second, imaginative designers of aircraft have also been proposing hydrogen as a substitute for aviation hydrocarbon fuel. Modern jet aircraft have voracious appetites for fuel: an average passenger in a plane with a load factor of 50% 'consumes' four times his own weight of fuel on a transatlantic crossing. Though it could be argued that this should be a priority outlet for oil products, some observers have claimed that there could be real technological advantages for hydrogen in aircraft use. Several preliminary design studies have been made of aircraft fuelled by hydrogen for both very high speed applications (Mach 5–6) and subsonic jumbo jets, but it is evident that much ingenuity will be required to avoid the very considerable advantage of low fuel weight per unit of stored energy being cancelled by problems arising from the high volumetric requirements for storage. If these design problems could be overcome, this could be an ideal use for hydrogen in transport, because fuel handling would be under strict control.

Finally, there is a hybrid fuel economy situation in which nuclear-based hydrogen could be used to adjust the C : H ratio of fossil fuels, as in the production of substitute oil or gas from coal.

Outlined above have been several contenders for the most likely new outlets for hydrogen if it can be produced more cheaply than at present and in much larger quantities. Assuming that the most feasible primary energy source for producing the hydrogen from water is the nuclear fission reactor and that the only feasible method on present evidence is by electrolysis using the nuclear-produced electricity (see below), it is of interest to consider the size of nuclear installation that might be required (Table 2). The number of reactors of the 1,000 MW class, currently a reasonably standard size for design and construction purposes, would be relatively small to meet United Kingdom needs compared with the likely installed capacity for electricity production by the end of the century.

Table 1 End-of-century fuel production costs in United Kingdom

	pence per GJ
Petrol (tax free) from crude oil*	140–220
Petrol from coal†‡	110–130
Hydrogen by electrolysis† (advanced technology)	135–175

Methods of production

The outlets discussed above lie in the range 10^5–10^7 tons yr^{-1}: at the upper end these are large by present day standards for any single country. Two processes are regarded as competitors to make the best use of nuclear energy for the decomposition of water. The energy could either be used directly as high temperature heat to promote thermochemical decomposition, or the nuclear energy could be converted into electricity and used in an electrolysis plant.

Although the electrolytic route introduces the additional step of electricity production with an immediate loss of up to two thirds of the original energy, it is often regarded as the reference process. A large development programme would be needed, however, to translate current practice into a successful and economic plant of the size required.

Several authors have demonstrated that the major component in the cost of hydrogen from large plants would be the price of the electricity. In order to minimise the latter, the advantages

of scale would need to be realised and nuclear stations producing about 1,000 MW are envisaged directly coupled to the electrolysis plants. Each 1,000 MW complex should be capable of producing about 150,000 tons yr^{-1} of hydrogen. This is about 70 times the size of the largest unit yet built, and a very much larger extrapolation from the average electrolytic plant.

The problems of such very large plants have not yet been fully assessed. It is already clear, however, that conventional electrolysers in which virtually all the industrial know-how at present resides will not operate at a sufficiently high energy efficiency to render them economically viable. It would be necessary, therefore, to develop new types of cell probably incorporating porous electrodes and operating at high pressures. One of the most interesting new concepts in this field is the solid polymer electrolyte cell described by L. J. Nuttall, A. P. Fickett, and N. A. Titterington at the conference on hydrogen economy, University of Miami, March, 1974. This cell has been developed primarily as a means of producing oxygen for aerospace and submarine applications, but it is claimed that it can be adapted readily for large-scale hydrogen production. The electrolyte is a solid plastic sheet of perfluorinated sulphonic acid polymer which is a good conductor of hydrogen ions, and the cells can be constructed in such a manner as to produce hydrogen directly at high pressures, thereby avoiding extra compression costs which might otherwise be incurred in optimum transport and use.

An alternative to electrolysis which is stimulating rapidly growing interest is the decomposition of water by closed-cycle thermochemical processes. At least 10 research centres are now actively interested in this possibility and over thirty potential cycles have appeared in the published papers. The prize is a higher energy efficiency than is possible in the electrolytic route, perhaps approaching a factor of two higher under favourable circumstances. It is disappointing that none of the cycles described so far is an outright winner. The most substantial programme on thermochemical cycles is that at the Ispra laboratory of the Euratom Joint Research Centre. An illustrative example of the range of cycles which they have proposed is based on reactions of the iron chlorides:

(1) $6FeCl_2 + 8H_2O \longrightarrow 2Fe_3O_4 + 12HCl + 2H_2$ 650°C
(2) $2Fe_3O_4 + 3Cl_2 + 12HCl \longrightarrow 6FeCl_3 + 6H_2O + O_2$ 200°C
(3) $6FeCl_3 \longrightarrow 6FeCl_2 + 3Cl_2$ 420°C

Insufficient experimental information is yet available on these reactions for a conclusion to be reached concerning the cycle's chance of technical success. As with all other proposed cycles, certain difficulties can be foreseen already: reaction 1 needs close control of temperature to avoid a path to different products, reaction 3 presents chemical engineering problems arising from the volatility of $FeCl_3$. Important constraints which can rule out some otherwise promising cycles are imposed by the upper limit of temperature which can be provided by a nuclear reactor system (because of limitations on materials performance in heat exchangers), the economic need to avoid exotic materials of construction (difficult when handling metallic halides at high temperatures), the requirement for high rates of reaction to cut down the size of the plant items and the need to avoid the recycling movement of massive amounts of solid materials in the plant.

Electrolysis will allow the earlier introduction of large scale hydrogen production if other factors are favourable, but if a more promising thermochemical cycle can be devised this route could take over in the longer term. There is insufficient information available at present for the thermochemical route to be costed.

Conclusions

Despite growing current interest, the widespread introduction of hydrogen as an energy carrier is still well in the future. But such economic forecasts as can be made on rather scant evidence do not rule out the possibility that hydrogen could be competitive with alternatives such as petrol from oil or coal, or nuclear-produced electricity, by the end of the century. These estimates are based on the production of hydrogen by electrolysis, but if a thermochemical route emerges from the substantial research programmes now being carried out, it would have the potential of considerably improving the prospects.

The safety aspects of the widespread use of hydrogen require close examination, but in principle no major stumbling block is likely to emerge. The introduction of hydrogen could, however, best take place in the controlled environments represented by aircraft and commercial road transport fleets, and industrial plants for the hydrogenation of coal or the direct reduction of iron ore. Use in the private motor car and as a general substitute for natural gas seem further off.

Above all, the advent of the hydrogen economy must depend upon the successful further development of nuclear power to provide the cheap reliable primary energy source for water splitting. The electrolytic route can be linked to the need for successful development of the sodium cooled fast reactor to provide the cheapest electricity in the long-term, whereas the thermochemical route needs a fully developed high-temperature reactor system to provide the high temperatures required.

Both routes to hydrogen would require a large development programme, with the thermochemical route currently lagging because a universally agreed attractive cycle has not yet been devised. At the basic scientific level the thermochemical route presents an immensely stimulating challenge to chemists, chemical engineers and materials scientists.

Solar energy

B. J. Brinkworth

Department of Mechanical Engineering, University College, Newport Road, Cardiff CF2 1TA, Wales, UK

Studies have been made of a very wide range of possible ways in which solar energy might be used for domestic and industrial purposes. Some are already economically viable and the prospects for others are improving through intensive programmes of research and development.

MAN has been using solar energy purposefully for millennia and will continue to do so, since it is the driving force for agriculture. In the pre-industrial era, it was the predominant source of power also, for the windmills, watermills and sailing ships of the time derived their energy ultimately from the sun. These devices could not have driven the subsequent period of industrial expansion because, without growing to inordinate size, they could not have made available generally powers greater than a

few hundred kW. They were well suited to modest local needs, but could not serve the demands of industry, concentrated in the interests of high productivity. This became possible only with the use of the concentrated solar energy stored in the fossil fuels. Yet we may shortly have to return to an economy directly powered by solar energy as the brief era of cheap fuel comes to its inevitable end. In the long term we have no choice; solar energy is the only perpetual source capable of meeting the likely demands of the future. We have some options in the short term. The fission reactor could support us for a time and will certainly ease the problems of diminishing fossil fuels, though it is not universally welcomed and a shortage of fissionable fuel is already envisaged. A fusion reactor would presumably defer a general energy shortage for a very long period, but it is proving elusive. It might be sensible to enquire whether the resources allocated to fusion research could be more profitably applied to the exploitation of solar energy.

Available energy

The decline of the windmill and watermill is traceable to the low energy flows available to any given machine. Though the total energy arriving from the sun is immense, the flux is very small by present-day engineering standards. At the top of the atmosphere the maximum value is about 1.3 kW m^{-2}, but a variety of scattering and absorbing processes reduce this to about 0.9 kW m^{-2} at the surface. The difficulties of effective utilisation are increased by the seasonal and hourly variations, which are functions of latitude, and by the random fluctuations due to the weather. In summer,

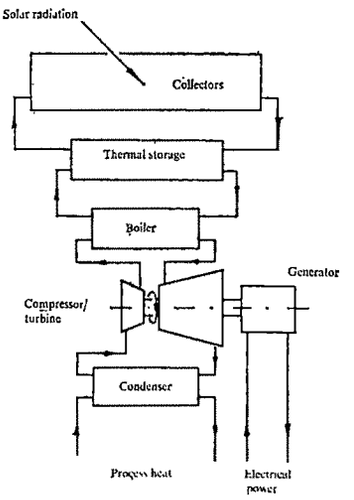

Fig. 1 Elements of thermal energy conversion system.

the increasing day length with increasing latitude helps to compensate for the longer air path so that in clear conditions the total energy received during one day varies only weakly with latitude. The winter isolation, on the other hand, is much affected by latitude; in Britain, for instance (latitude about 52°), a clear day in midwinter yields only about one-tenth of the energy of one in midsummer.

The total annual insolation (energy incident on a horizontal surface) is around 1.5 MW h m^{-2} over large areas of the earth and in places it exceeds 2 MW h m^{-2}.

The effects of climate, though substantial, are less than is usually supposed. The average annual insolation in Britain, with its notorious cloud cover, is nearly 1 MW h m^{-2}. Britons are usually surprised to learn that, on average, the United Kingdom receives more than half the energy available in Australia or two-thirds of that in the United States. The large droplet sizes of cloud in relation to the wavelength of the radiation causes predominantly forward-scattering, so that a sizeable fraction penetrates unless the cloud is optically very deep. At the same time, the radiation becomes diffused. Due to the high cloud cover in Britain an unusually high proportion—more than half—of the radiation reaching the surface there is diffused. This is important because this part of the radiation cannot be brought to a focus.

Large scale use

The entire world energy demand for human purposes other than agriculture is less than the solar energy falling on a region 100 km square in a favourable location. This is a trifling area compared with that of the world's land surface or even of the deserts, but it is very large on the scale of human constructions. Inefficiences in the energy conversion processes used would mean that even greater collecting areas would be needed. Nevertheless, serious study has been given to the design of 'solar farms' thousands of square kilometres in extent[1]. In these, the collectors concentrate the radiation so as to produce in a working fluid a temperature high enough to operate a

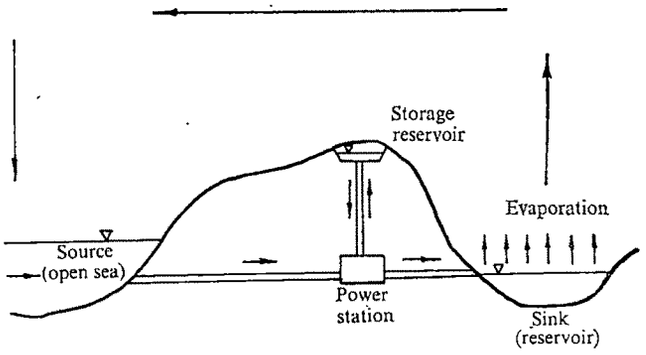

Fig. 2 Heliohydroelectric scheme, with pumped storage.

thermodynamic engine with respectable efficiency. An intermediate fluid might be used to link the collectors to a thermal storage element which permits a match to be obtained between the energy supply and the demand (Fig. 1). The cost of collectors is a significant factor in all uses of solar energy. When they are of the concentrating type, they need to be robust to maintain good fidelity of shape and resistance to wind forces and they must be steerable to follow the apparent motion of the sun. Useful temperatures can be obtained from two-dimensional parabolic troughs with the focal line orientated east–west, requiring only a slow seasonal adjustment to follow the sun's declination. It might be foreseen that these could be mass-produced in modules of moderate size which could in principle be indefinitely replicated to build up a large station.

The cheapest large scale collectors, in terms of cost per unit area, are reservoirs. A scheme recently advanced on this basis involves the Qattara Depression in the Libyan Desert[2]. It is proposed that this region should be connected to the Mediterranean, about 80 km away. The high evaporation rate, about 1.7 m a year, would maintain a free water surface 12,000 km^2 in area within the Depression at about 60 m below sea level. This would be sufficient to operate a hydroelectric plant of about 4,000 MW capacity, as shown in Fig. 2.

The ultimate in large collectors is the sea itself. Power plant exploiting the temperature gradient in ocean waters was first constructed in 1930[3] and the possibilities have been re-assessed more recently. Though the small temperature differences available inevitably mean low thermodynamic efficiency, the economics are by no means unfavourable[4].

Large scale systems such as these effectively combine the functions of collection and storage. A corresponding

arrangement on land might make use of the photosynthetic manufacture of combustible hydrocarbons. There is already a world shortage of timber and presumably of land suitable for traditional afforestation, but official studies in the United States[5] and Australia[6] both comment on the relatively small fraction of land area which would be needed for the intensive cultivation of fast-growing plants capable of furnishing a significant proportion of the energy demand. It is to be noted, however, that studies have yet to be made of the engineering problems of harvesting, transport and processing involved in such a scheme. These studies are urgently needed, since photosynthesis offers the most direct path to the manufacture of liquid and gaseous fuels which will probably continue to be needed indefinitely for transport.

A major objection to all schemes for the conversion of solar energy on a large scale at central stations is that there is very little freedom of choice on where they might be sited. Nearly always, they will have to be distant from the places in which the energy is to be used. This not only requires expensive distribution networks of power lines or gas pipelines, but raises the possibility of undesirable climatic effects arising from the transfer of energy on a large scale away from the places at which it has hitherto been absorbed. These and other factors have led many to the view that the proper scale of solar energy conversion is local rather than central. As this is a reversion to its pre-industrial use, it follows that some attention will be necessary to the methods of integrating such a source with the others that will be available, particularly in urban-industrial societies.

But, throughout the world, there is a huge potential requirement for devices with capacities ranging from a few watts to a few tens of kilowatts. About 80% of the Earth's population lives between the 40° parallels, including many of the poorest, but they can nearly all count on an energy flux exceeding 1 MW h m^{-2} yr^{-1}. It is more instructive to compare this, not with the million MW h per year required from a European power station, but with the level of local demand: the 1 MW h yr^{-1} of work performed by a pair of bullocks, or the 100 kW h needed to winnow the grain from a family's land. All the hot-water needs of a clinic and the refrigeration of its wards and theatres could be provided by the energy which falls on its roofs. The roof of a dwelling could furnish power for a loom or lathe; that of a barn enough for a pump, able to irrigate 10 hectares of land. A school's radio and television receivers could be powered by a device the size of a blackboard; a solar still the size of a duck pond could yield enough drinking water for a village.

Power for small local enterprises like these cannot be provided economically by large-scale generation at central sites, even by conventional means, largely because of the high cost of transmission where the population density is low. The cost of fuels for local power plant is also greatly inflated by distance, doubling in a few hundred km over land. It is being recognised that rural communities must be given more stability and, for this, work and amenity must be provided within the village. Solar-powered devices could substantially raise productivity in such local enterprises as weaving, timber sawing, paper milling, food processing and preserving, light manufacturing, plant maintenance, irrigation, fresh water supply, drainage and a host of other activities. By these devices, it may yet be possible to revitalise the village from within.

Local use

The conversion of solar energy for modest local demands has been the subject of experimental investigation for many years. It is known that solar stills, solar-powered engines and other devices were successfully operated a century ago. But they were unable to compete economically in an era of cheap fuel and their credibility suffered through the unguarded optimism of enthusiastic advocates whose claims were easily discredited. More recently, these devices have begun to receive sober engineering and economic analysis, exemplified by the contents of two specialist journals devoted to the subject: *Solar Energy* (Pergamon Press) and *Geliotekhnika* (available in translation as *Applied Solar Energy* (Allerton Press)).

Quite thorough studies have now been made of ways in which solar energy might be used on a local scale[7,8]. These include its direct use for heating and cooking; driving a thermodynamic system, as in distillation, desalination, air conditioning, crop drying and so on; providing a source for heat engines, refrigerators and heat pumps; direct conversion to electricity using thermionic, thermoelectric and photoelectric generators; and the promotion of photochemical and photobiological processes leading to the generation of electricity or the production of liquid and gaseous fuels and other chemical products. Some of these processes are already economically competitive and their position is bound to improve as fuels become scarcer and dearer.

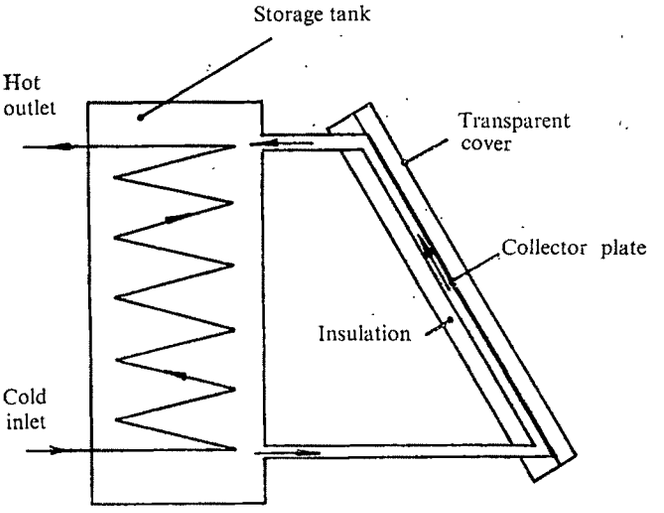

Fig. 3 Solar collector for domestic hot water system.

Flat-plate water heaters, of the kind illustrated in Fig. 3, are already widely used in many parts of the world and are now being marketed by several manufacturers in Britain. Up to about 60% of the incident energy can be transmitted to the water at useful temperatures (40-50° C) if the re-radiation is minimised by the use of glass cover plates, in the manner of a greenhouse, and of selective coatings on the absorbing surface which combine good absorptivity for solar radiation with low emissivity at working temperature. Heaters of this kind already make significant contributions to energy supplies for domestic, commercial and industrial purposes and their use is certain to grow[6]. Usually, they are linked with conventional heating systems and act as fuel savers rather than being designed to meet the entire heating load. It is estimated that in Britain they could yield about 10^6 MW h yr^{-1} for each 1% of dwellings equipped with them[9]. Much work is in hand worldwide to obtain a significant contribution to space heating and air conditioning from solar energy, and the design of buildings to exploit this is becoming a major preoccupation of architects. There is a history of building experimental 'solar houses' extending over some decades, in which Britain has had its share. In these, there has to be a means of energy storage to accommodate the seasonal and daily

variation in the energy available, and the fluctuations due to the weather. Thermal storage is obtained by changes in the sensible heat of a reservoir, which may be liquid or solid, or by latent heat exchange during a change of phase of the storage medium. Optimisation studies show that it is economical to obtain from the sun a significant fraction—typically ⅓ to ½—of the heating requirements of ordinary dwelling houses, even at quite high latitudes[10]. A typical domestic arrangement is shown in Fig. 4.

The economical provision of mechanical work and electricity on a small scale is proving elusive. There is little to choose in capital cost between low temperature heat engines driven by flat-plate collectors and more efficient ones with concentrating collectors. Both are still much more expensive than other sources such as the small diesel engine. But there are places where fuel costs are unusually high due to transport charges, where the net cost of work from solar engines would be competitive. These should be simple and robust and capable of being built using local resources. Their adoption will demand more from the entrepreneur than the engineer now.

On the other hand, much technical work remains to be done on direct conversion to electricity. Devices such as thermionic and thermoelectric generators require the maintenance of a temperature difference for their operation and hence have a restricted efficiency for thermodynamic reasons. Thermionic generators can operate effectively only with a high cathode temperature, perhaps of the order of 1,500 K, and this implies the use of concentrators of good optical quality, capable of tracking the sun accurately. This and other technical features have caused the thermionic generator to fall into disfavour for solar energy conversion, though it is capable in principle of quite good overall efficiency. Thermoelectric generators are subject to certain material limitations as well as thermodynamic ones, but continue to be of interest, even for use with flat-plate collectors, because of their simplicity. Photovoltaic cells, developed primarily for use in spacecraft, have reached useful conversion efficiencies—about 15% in full sunlight. Some, such as the GaAs/GaAlAs cells, function well in highly concentrated light. But these are single-crystal cells produced by very expensive processes. At a capital cost of some £10 to £100 per W of installed capacity, their use can so far be justified only in very specialised applications such as the powering of active buoys and other remote navigational aids and radio stations. Strenuous efforts are in hand to reduce the cost of photocells. This might be done by the development of large scale methods of production, perhaps of silicon ribbon which retains a single-crystal structure[11] or of thin-film polycrystalline cells. If capital costs are sufficiently low, quite small conversion efficiencies may be acceptable—the 8% reported for CdS/Cu_2S heterojunction cells[12], for example.

Outlook

It seems certain that non-agricultural uses of solar energy will continue to increase throughout the world, as the fossil fuels become scarcer and dearer. Already solar water heating is competitive in many countries and solar space heating seems about to become so. The outlook for conversion into work and electricity in the near future seems promising but is less certain. The principles are well established, and many devices have been built and tested in prototype form, but much more work remains to be done before they can have an assured place in the energy economy.

There is every sign that the necessary research and development work related to effective solar energy utilisation will be carried out promptly, at least as far as the needs of the developed countries are concerned. A US National Science Foundation report of 1972[5] recommended a commitment of $3,500 million in this area, justifying this with

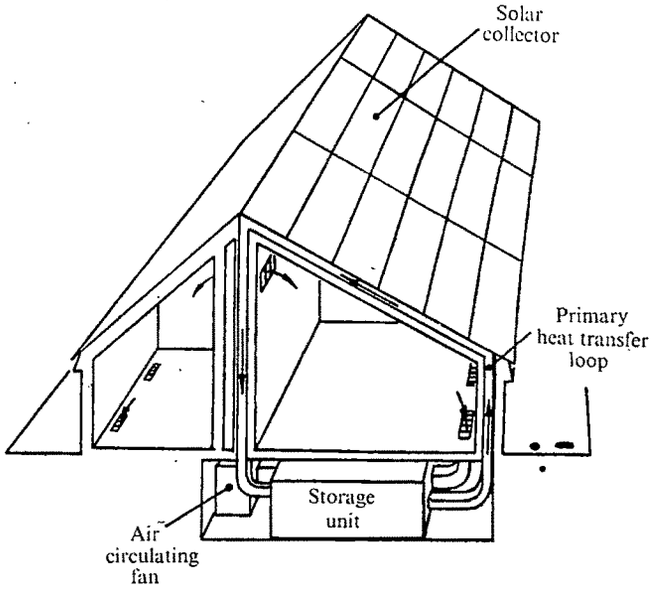

Fig. 4 Solar space heating system.

the contention that solar energy could provide 35% of the nation's heating and cooling requirements for buildings, 30% of its gaseous fuels, 10% of its liquid fuels and 20% of its electricity. These recommendations are being pressed ahead with extraordinary vigour; already the annual research budget for solar energy work has reached about $15 million. A somewhat similar programme, though not yet funded, was recommended by the Australian Academy of Sciences last year[6]. This suggests that solar energy could provide 40% of Australia's low grade heat and 50% of her liquid fuel within 25 years. The Soviet Union has maintained several centres for solar energy research for many years. Japan, long known for its widespread use of solar water heaters, is planning a major new solar energy programme said to be comparable with the American one.

There seems to have been little official support in western Europe though there has been some activity in the universities and the interest of industry is awakening. It remains to be seen whether this work will benefit the underdeveloped countries, which in many ways, are in most need of it. They usually have little indigenous fuel and are severely affected by rising fuel costs. On the other hand, they generally have ample solar energy, with little seasonal variation and a population which is still largely dispersed (but is drifting to the towns at an alarming rate). The encouragement of a greater use of solar energy in these countries could be the most sensible and effective way of giving financial and technical aid.

Tidal energy from the Severn Estuary

T. L. Shaw

Department of Civil Engineering, University of Bristol, Bristol BS8 1TR, UK

Energy generation from the tides is widely regarded as economically less viable than that from conventional thermal alternatives. Although economic comparisons are unfavourable the potential overall improvements in network operation indicate the true value of new plant.

In operation, a tidal power scheme could possess much of the flexibility of highly versatile, conventional hydroelectric stations, and many types of project have been suggested. To assess in 1974 the preferred style of operation (not only for a tidal scheme but also for new thermal plant) necessitates anticipating consumer and generating demands beyond 1984, for it will not be until then, and for a long time afterwards, that any scheme planned now, whether tidal or otherwise, would be working. In particular, after 1984 a substantial nuclear component will emerge in the generating structure of all those industrial countries which opt for thermal energy schemes (few are even now able to rely on further conventional hydroelectric sources, and stations which require fossil fuels are unlikely to be favoured in large numbers). Coupled with the present crises in the provision of fossil fuels, and the complementary gross escalation of their costs, it is no surprise to find that the status of tidal power has, psychologically at least, improved markedly.

The last detailed, government-sponsored study of tidal energy in the UK was concluded in 1945; it was prompted by the additional power requirements of the war effort, and it leant heavily on the results of the only major UK study, of the Severn Estuary, which was completed in 1933. The schemes anticipated at that time were on a relatively small scale. A favoured site for the barrage was well up the estuary at English Stones, just below the present Severn Road Bridge (Fig. 1). The maximum power output would have been about 800 MW, over 10% of the maximum demand during the 1940s.

Canada, France and the USSR have since been studying more actively their own potential for tidal energy generation. The best site in the World, however, is probably the Severn Estuary. The Severn is not excessively deep or wide, the tides are almost the highest occurring anywhere, and it is near to centres which require a high energy load. But despite these advantages, which have been appreciated ever since the first studies, it is now more necessary to give close consideration to ecological factors than it was 30 years ago. Harnessing tidal energy must be seen to be not only economically and functionally competitive with other forms of generation but, in addition, must be environmentally acceptable in its own right. After all, the crisis in fuels is not so serious that all other considerations have to be overlooked, and in any case even the Severn Estuary–Bristol Channel could not provide more than about 25% of the present peak total demand for electricity, a ratio which will have declined considerably by 1984.

Energy potential of the tides

The rhythm of tidal variation from place to place, and from time to time at any place is well known. A few sites, like the Severn Estuary, the Bay of Fundy (Canada) and the Ile de Chausey (France) have exceptional spring tidal ranges of 14–15 m; and the range is over 16 m in Ungava Bay (Canada). These particularly high ranges only occur locally within each embayment, as a result of both focusing effects and a measure of resonance between the tidal and natural frequencies of oscillating water within the boundary of the estuary. Progressively lower maximum tides occur away from the optimum positions.

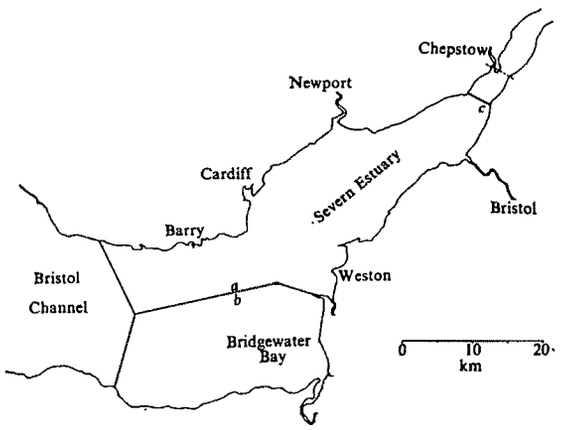

Fig. 1 Outline map of the Severn Estuary and Bristol Channel, showing the barrage scheme proposed by Martin in 1945. *a*, High level basin; *b*, low level basin; *c*, 1933/45 barrage proposals.

Much less favourable circumstances for energy generation apply during neap tides, when the range is typically about one half of that during spring tides. Inequality between the lunar and solar periods is responsible for this spring–neap–spring cycle, which takes nearly 15 days; it also gives rise to a tidal period of 12.4 h. Generation is therefore not possible over more than about 4 h during both the ebb and flood tide phases (Fig. 2), and the amount of energy, as well as the times at which it becomes available, vary from day to day. Nearly half of the output will coincide with off-peak times (peak demands for electricity now extend up to 14 h, from 0800–2200h).

Although, compared with generation from solar, wave and wind sources, the tides could be regarded as a relatively predictable form of natural energy, the form of output is still inadequate for electrical networks which depend heavily on thermal plant to meet a fairly predictable daily pattern of demand. To incorporate tidal energy into these networks an equivalent amount of thermal plant would have to stand by to carry the load when the state of the tide was not suitable for generation. This extra plant would have to be provided and run at low thermal efficiency (because duty periods are short), whereas continuous operation without the tidal scheme would produce the same output at a much improved efficiency.

Regularised output from a tidal scheme

The various limitations of the tides, quite apart from economical factors, have been a considerable barrier to

commercial development during this century. Earlier (tide mills can be traced back to 1180, at Dover), the consequences were accepted only in the absence of more reasonable alternatives. But methods of improving the regularity of output have been proposed, although they involve extra costs and energy losses:

- Power could be transmitted as and when available, either to the consumer by day or to a pump storage station. The latter alternative involves two reservoirs at differing elevations, interconnected through pump turbines. Many such installations now exist, storing energy from thermal power stations at night, for daytime release to meet short term peak load and emergency conditions. Over 75% storage efficiency can be achieved, so that six hours of pumping gives about four and a half hours generation at the same rate, when required. This technique was favoured in the 1933 and 1945 Reports. With tidal power, however, the additional costs fail to overcome the basic economic objections to tidal energy production.
- Two basins could be constructed in the estuary, each filled and drained when the tide is high and low respectively; energy would be generated by flow between the basins. This alternative was adapted by C. A. Martin (unpublished) for the Severn Estuary in 1945 (Fig. 1). Continuous output thus becomes possible; in Martin's scheme it varied between 3,350 and 850 MW. Unfortunately, however, publication of this imaginative scheme coincided with a slump in energy demand, and in any case it was ahead of its time in terms of the size of plant needed to provide for the normal annual growth rate in demand of that period.

Other schemes resembling that of Martin have followed as the scale of the second era of barrage planning has become more commensurate with requirements. For economical reasons, large thermal installations have also become fashionable: new stations, including nuclear plant, are, or soon will be, about 2,000 MW (in a 50,000 MW network). This trend is likely to persist as the nuclear proportion of the total installed capacity escalates towards 50% by the end of this century. After 1990 the nuclear energy component will therefore be greater in magnitude than the normal night time demand (equal to about 40% of the daytime demand). When this happens, all plant which use fossil fuels will have to be operated only during the daytime if nuclear stations are to be run continuously. Thereafter, the operation of nuclear stations would have to become flexible, involving not only further development and capital costs, but also a drop in the operating efficiency and extra fuel costs. This cannot be avoided unless excess energy is either discharged to the environment in the form of heat, or is supplied to pumped storage facilities.

I have already mentioned the fact that the use of pumped storage facilities allows energy to be regenerated as required, although bulk energy transfer from night to day should be distributed uniformly over the 12–14 h demand period if equivalent thermal plant (that is, the older, smaller and more uneconomic stations) are to be displaced entirely from the system. Given that pumped storage could be operated in this way, that is, in addition to the present duty of meeting relatively small variations in demand, there could well be merits in adopting it before a 'nuclear excess' situation arises. That would allow many of the more efficient fossil-fuelled stations which would otherwise have to be shut down at night, to be run continuously with an improved efficiency. In the limit, the ideal situation (which is not unobtainable in this case) would be to run all thermal plant, equivalent in capacity to about 75% of the maximum demand, on a continuous basis, and carry over from night to day accordingly.

The major objections to pumped storage installations are probably environmental. Creating reservoirs for any purpose receives little spontaneous sympathy from the community at large, especially when these cannot be made available for recreational purposes. Recently, the Central Electricity Generating Board (England and Wales) has experienced strong opposition to these projects; their new Dinorwic scheme in the Snowdon National Park in North Wales is regarded by amenity groups as aesthetically and environmentally unacceptable, because, they claim, it will spoil famous landscapes, and introduce extensive 'tide mark' scars as the water level changes more than 100 feet in four hours (three times the rate of rise and fall of the remarkable Severn Estuary tides).

Although, at 1,400 MW, the Dinorwic scheme will become the largest in Europe, its purpose will be more for short term supplementation of supply than for bulk energy transfer for consumption over 12–14 h. In fact, the latter style of operation would require 20 installations like Dinorwic to yield even 10% of a demand of 100,000 MW (the probable installed capacity soon after 1990). This is an unreasonable objective for pumped storage in its present form, even though 10% of installed capacity is still well short of the ideal referred to earlier. Understandably, alternative forms of pumped storage are being earnestly explored.

Martin's concept and estuarine pumped storage

The necessary difference between the water levels in the two basins of a pumped storage scheme may be achieved by using surface and underground reservoirs, which suggests that the sea and natural caverns should be exploited where available. An alternative would be to follow the principles adopted by Martin, and store energy by increasing the difference between the levels in two basins formed in an estuary. This variation has been evaluated by my colleagues and I, resulting in the type of scheme shown in Fig. 3 (the preferred energy capacity and geological conditions would dictate the actual location of barrages).

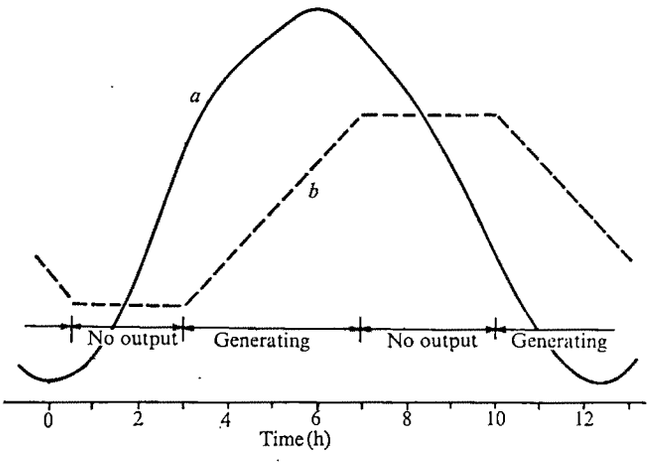

Fig. 2 Variations of tide level and the level in the basin, showing periods of generation.

The basic layout is somewhat different from that proposed by Martin (*et al.*), for here the second basin is small in area and sited entirely in deep water, so that the level can be reduced by pumping at night to well below low tide level, without the effects being felt on the coastline. The level in the larger basin is raised during the same night time period, but not to a level higher than that of the present high spring tide, thus avoiding problems of land drainage and removing the risk of floods which result from exceptional tidal surges.

From a scheme such as this it is possible to withdraw 4,000 MW at a constant rate (if that proves to be the preferred style of output) over the same 12-hour period every day, irrespective of the tidal range. The power from thermal

stations supplied to the scheme at night is also 4,000 MW, over a period of nearly 8 hours (the need for weekend variations in this pattern is recognised). This equality between the rates of pumping and generation makes the best use of available equipment. The scheme (Fig. 3) could be supplying 6% of daytime consumer demand by the mid 1980s, which, from one power station, is a reasonable increase in generating capacity. Similar but larger projects, operating in the Severn Estuary–Bristol Channel, could also be devised.

Economic and other factors

The economical value of a scheme of this type can be assessed on the following basis. For night time pumping using energy from thermal stations, the alternative to estuary storage on the scale of the scheme I have discussed (Fig. 3), would be three schemes each bigger than the Dinorwic project. In addition, harnessing tidal energy by the simplest of projects, akin to the 1933 scheme (Fig. 1) but involving the main enclosing dam shown in Fig. 3, would require a similar, additional amount of pumped storage potential. Making provision for this in an estuary, in such a way that firm daytime output is available, makes the scheme in Fig. 3 equivalent to thermal plant of the same capacity operated only by day. This equation should also take into account the fact that the tidal–pumped storage scheme permits other thermal plant to be run continuously rather than be cycled.

The combined estuary scheme would thus displace the equivalent generating capacity of nuclear plant having a cycling capability, that is an installation costing at least £1,400m—probably much more—at 1974 prices. This scheme would have a capacity of 4,000 MW and its operation could be achieved by the estuary project but without fuel costs other than for the purchase of energy at night from thermal stations. On this basis it is realistic to believe that the estuarine scheme is both economically preferable and operationally equivalent to the nuclear alternative.

Many other factors have to be considered in the moderately complex but technically straightforward operation of this type of estuary development. Basically, it is little more demanding on plant than are other tidal proposals, even though its performance is easily rendered compatible to energy requirements, through the pumped storage addition. Unlike the next round of nuclear stations the estuary scheme relies heavily upon proven technologies. Only two main components are involved, embankment construction, which has been explored in great detail, especially by the Dutch, and pump turbines. Several new types of hydraulic machine for extracting energy from small differential water levels have been devised recently, and these may be well suited to estuarine tidal schemes. Machines pioneered by the French in the 1950s, for the small tidal scheme at La Rance, Brittany, have now been well proven over many years of service, and would also meet this duty.

It is worth recording that the French project is similar in size and purpose to the Dounreay and Winfrith nuclear installations: all are about 250 MW and, although experimental, they are also useful contributors to the national network. To scale up their costs *pro-rata* would be as inappropriate as applying costs from La Rance to the proposed scheme (Fig. 3) in the Severn Estuary, or to the large Ile de Chausey project, for which La Rance was the pilot. In fact, Ile de Chausey was shelved as soon as La Rance was completed, because it was essentially a tidal energy project with the attendant disadvantages already outlined (it had been envisaged that there would be some pumping when the tides permitted).

Environmental considerations

The energy figures discussed here for the combined estuary installation, were evaluated within specified environmental restraints; more energy could be provided but this would create less acceptable conditions elsewhere. Land drainage and flooding have already been mentioned as factors limiting the height of the water level along the coastline. The high tidal range in this comparatively shallow estuary creates strong currents and exposes extensive mud flats at low water. Because of the currents, a large amount of sediment is held in suspension, and much of this settles out when the tide turns. Very little material seems to move seawards into the Bristol Channel, and therefore reservoirs constructed as shown in Fig. 3 should not suffer problems of sedimentation: the bulk of the material would be deposited over the area of the main reservoir in a layer consolidating to an average depth of only a few millimetres. Further inputs of sediment from the rivers could give rise to some local accumulations of deposits, but as there would be a 'tide' range of over 10 feet in this reservoir, currents of a strength comparable to those occurring in many estuaries and coastlines would still occur.

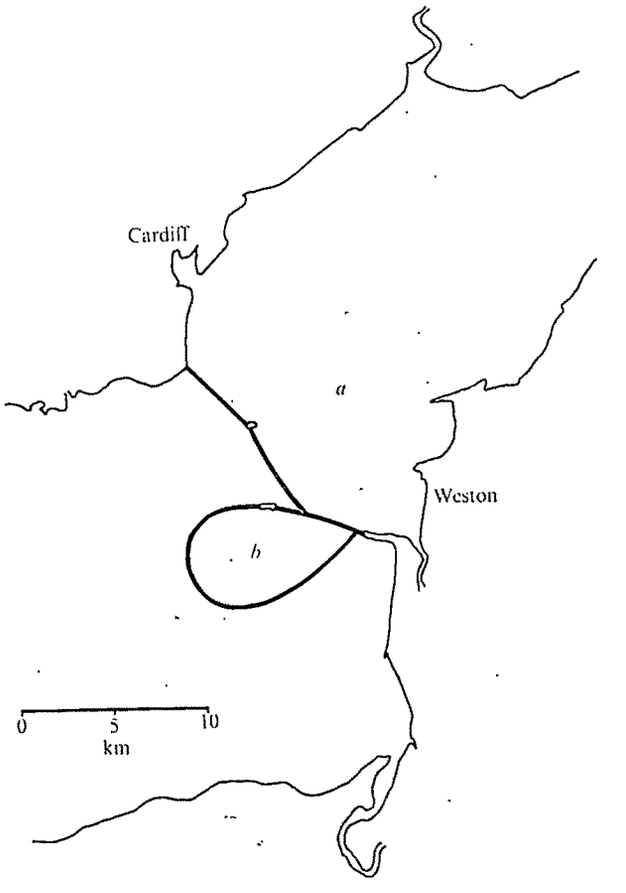

Fig. 3 Suggested barrage scheme: *a*, high level basin; *b*, low level basin.

The loss of the mud flats over much of the estuary will not be generally mourned, although there would be some ecological effects. The present combination of strong currents and high concentrations of suspended solids leaves little room for sustained marine life, and reduced currents and improved water clarity would, therefore, generally improve feeding conditions. This should promote greater fish populations, and these would pass through the large, slowly rotating pump/turbines.

Wildfowl must also be considered in any review of environmental factors. One of the most extensive areas of mud flat used for feeding is Bridgwater Bay, immediately seaward of the barrages outlined in Fig. 3. The tidal regime for this area would remain largely unaffected although there would be some reduction in the currents. Further up the estuary the substantial rise in mean water level caused by

the barrage, would become less significant than the higher levels created at present by the tidal surge. The low water levels, which are influenced more by the general bed profile of the river system than by tidal processes, would change relatively little. Thus, at the Slimbridge Wildfowl Trust, upstream of Sharpness, the pattern of flooding and exposure of feeding grounds might be influenced more by the 24-hour cycle of operations than by the modified range of water levels created by a barrage.

Overall effects

The future for tidal energy may be bleak, but an integrated estuary pumped storage project of the sort described offers worthwhile economic and operational advantages over a pure tidal development. In particular, because circumstances at present and in the foreseeable future favour such a project, it is timely to give the matter closer attention. Industrial, social and environmental matters must not be overlooked, not least because these could and should be permitted to benefit from such a project.

Some environmental aspects have been referred to above. On balance it seems that a net improvement over the present, somewhat suppressed ecological regime could be achieved, although more detailed studies of several aspects are required if there is to be an adequate picture of the probable changes resulting from a barrage. Many industrial and social factors also arise, such as benefits to shipping, inland road and rail communications, and the provision of a very large area for water recreation in a part of the UK that has managed to attract a population of three million despite the lack of social appeal of its estuarine focus.

It is to be hoped that energy planning in such circumstances would not be daunted unduly by the prolific interaction of seemingly complex factors, especially as even the potential power output need not be reduced significantly in order to provide other sectors of the community with wide benefits that are, in their own way, just as much in the national interest.

Nuclear options

G. R. Bainbridge

United Kingdom Atomic Energy Authority, Risley, Warrington, Lancashire, UK

Dr G. R. Bainbridge is Manager of Technical Assessments in the Reactor Group of the United Kingdom Atomic Energy Authority. At the beginning of August he takes up his appointment to the new Chair of Energy Studies in the University of Newcastle upon Tyne. Here, he discusses the nuclear fission reactor options which Britain could take up during the next decade and gives an outline of the broad energy requirements for which nuclear reactors are needed.

BRITAIN took a first option which led towards the application of nuclear fuel to supplement traditional coal and oil supplies almost 30 years ago. It was to pursue techniques for controlling nuclear fission reactions on a large scale, thus making heat available, and manufacturing plutonium. Most of the nuclear research and development work in the world at that time was financed by military budgets. The construction of the Calder Hall plant, the first unit of which was completed in 1956, was no exception. But its most remarkable success was in the supply of by-product electricity, design data and operational experience for the later commercial nuclear power stations. It is easily forgotten that Britain achieved her first peacetime nuclear power objectives quickly and alone. It would be sad if transient commercial expediency led the country to take risks now by adopting nuclear reactor designs from abroad which are in some respects technically less sound than those produced at home.

Britain now gets 10% of her electricity from nuclear power stations (Fig. 1) which use natural uranium fuel and thus save 9 million tons of coal, or 5 million tons of oil each year. That is, however, only 3% of the total national fuel requirement (Fig. 2) and there is recognised scope for a more significant contribution as time goes on.

When a country is embarked, as Britain is, on a course of applying such a rapidly advancing technology as nuclear power, it is of benefit to review periodically and unhurriedly the available alternatives. The most important review of the 1970s is now in progress, and it could have very important consequences for Britain's nuclear power strategy. With a wealth of nuclear experience to her credit, the country is more favourably placed than ever before to survive any future shortages of fossil energy and rising fossil fuel prices, by arranging a strong nuclear power programme for electricity generation. Indeed, if a combined 'energy resources and use' strategy can be formulated to include a complementary plan for all of the available fuels, the 1980s should see Britain in a better position for energy than for many years past.

To reach that position, in which fossil fuels can be conserved or exported as well as being used rationally at home, I believe that action must be taken to provide most of our incremental electricity generating capacity, including replacement plants, in the form of nuclear power stations. This implies that 30,000–40,000 MW of nuclear capacity should be ordered in the next decade and built before 1990 (Fig. 3). A further 70,000 MW will have to be ordered

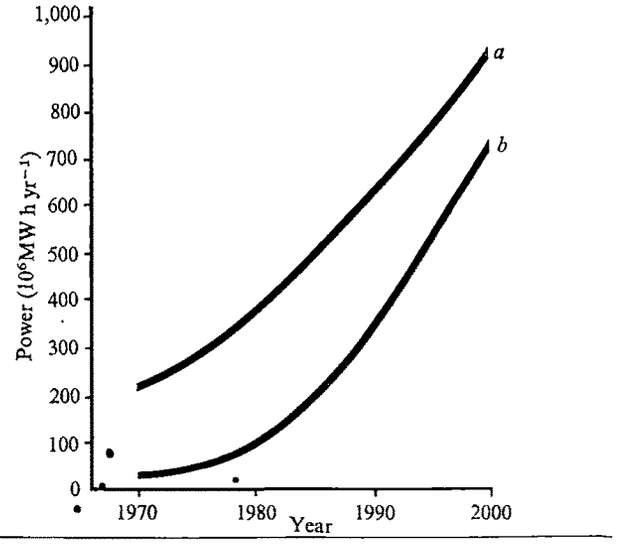

Fig. 1 The total electricity demand (*a*), and nuclear power supply (b), in the United Kingdom.

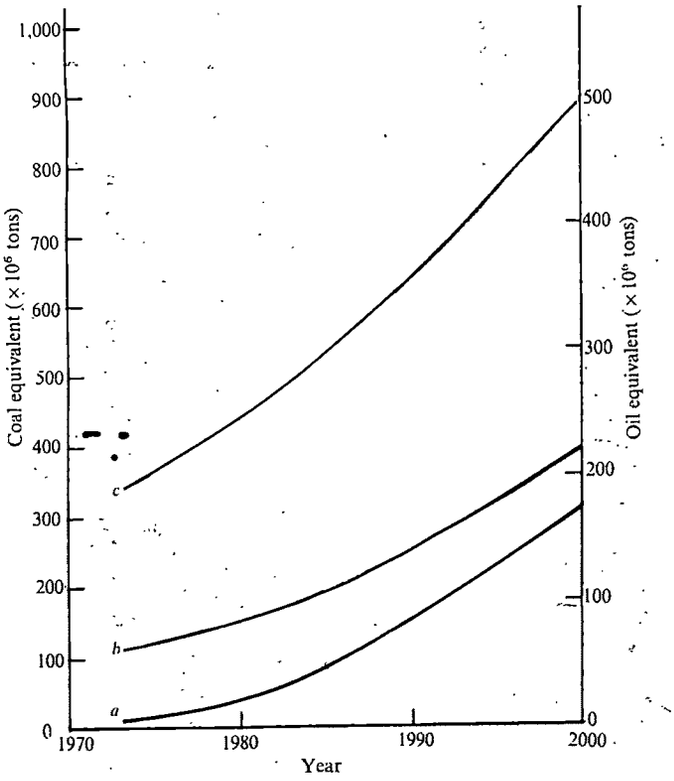

Fig. 2 Primary energy consumption in the United Kingdom. *a*, Nuclear electricity; *b*, total electricity; *c*, total.

between 1985 and 1995 for operation before the end of the century. That will enable nuclear power to supply in the region of 80% of the country's electrical energy usage (Fig. 2); around 30% of the country's total energy usage at the end of the century.

An expenditure of around £8,000 million will be required for the nuclear power station plant completed during the next 15 years alone, and £600 million will have to be spent on replacement fuel (Fig. 4). The task will not be easy to accomplish, even with a well established and financially strong National Nuclear Corporation (assuming that this is soon realised). The investment sum is over four times that of the first 20 years of commercial nuclear power. During that period there have always been two or more consortia, or design and construction companies, working with the Electricity Boards in order to get the initial 10,000 MW or so of nuclear plant into operation. But British industry as a whole has achieved similar objectives previously. The expenditures on an alternative oil station programme for the same electrical capacity would be £4,000 million capital outlay, and almost £7,000 million for fuel; 30% higher than the cost of nuclear plant in those initial fifteen years of construction and operation. At no time after about the third year of operation would the total expenditure on an oil programme be less than that of a nuclear programme. From then on nuclear fuel would cost only £1,500 million a decade, whereas the 550 million tons of oil, which would be used during the same period, would cost £16,000 million. Similar figures emerge if coal, and not oil, is considered as an alternative to nuclear power.

If this main nuclear programme objective is to be achieved, then the other nuclear commercial options will have to be allocated a much lower priority. It can be anticipated, however, that although the types of nuclear reactor selected as the best that Britain could build next may be suitable for unit designs with a nett output exceeding 600 MW, with minimal adaptations some of them might be provided in smaller unit sizes overseas. At present, power stations with nuclear units of 300±200 MW could be competitive with oil-fired designs, provided that the price of oil stays high in relation to that of nuclear fuel (at present about 6:1) and that the capital cost of oil plant relative to nuclear plant does not decrease (at present 0.7:1), (Fig. 5). For exports, which would relieve the pressures of commitment in a heavy home programme, a separate organisation of companies could be formed profitably, allied at home with the main National Nuclear Corporation, and overseas with interests already actively engaged in attracting nuclear power station business.

Other factors affecting the choice of reactor, such as the supply of industrial process and urban living 'comfort' heat, need to be considered separately from the main issues of this article. The provision of nuclear reactors for the propulsion of large, fast, container ships and oil tankers are also outside the main issues discussed here, as they would be additional and special in many respects.

If resources are to be used sensibly, and there is to be high morale and enthusiasm amongst those engaged in the

Table 1 Nuclear reactor options—parameters

nuclear power station development and manufacturing industry, and if the paying public is to remain confident that nuclear power is in their own and the nation's best interests, then expeditious decisions must follow any review. This is particularly important when review procedures have been conducted at the highest political level, as has been the case in recent months. A Parliamentary Select Committee, an eminent Nuclear Power Advisory Board, four ministers and two governments have been involved.

Whether under the new policy, the established line of action is continued, or new, previously unforeseen conditions are met with a change of direction or pace, there must be adequate early publicity about the co-operation necessary for rapid progress. The present review must not end up as a little reported non-event, as did the thermal reactor and fast reactor reviews of a few years ago.

Nuclear reactor options

The objectives of low cost, plentiful, reliable, safely available nuclear energy must be kept in sight, for it is easy to be distracted and repeat old errors. Accepting these limited objectives, however, it is possible to argue that the logical progression in the use of gas-cooled reactor designs which Britain began to operate in the 1950s, could fulfil not only all her own needs but also those of some other countries. Table 1 gives typical parameters for gas-cooled reactors and for the main available alternatives.

Calder Hall was the first nuclear power station to feed substantial amounts of electricity into a national grid distribution system. The uprated output, now at 200 MW, regularly exceeds the original (perhaps conservative) intended output by 50%, and it also feeds process steam to the adjacent Windscale site. Moreover, its sustained performance over almost 20 years (an accountant's plant amortisation period) is, together with that of its twin station at Chapelcross, better than that of any other plant in the world exceeding 100 MW in output, whether nuclear or fossil fired. Year after year it exceeds 90% load factor even though it has to be shut down occasionally for refuelling. Such is the confidence that these plant can continue to operate at a low cost, that there is a current survey of the components which could be refurbished usefully in order to give the stations 20 to 30 further years of life.

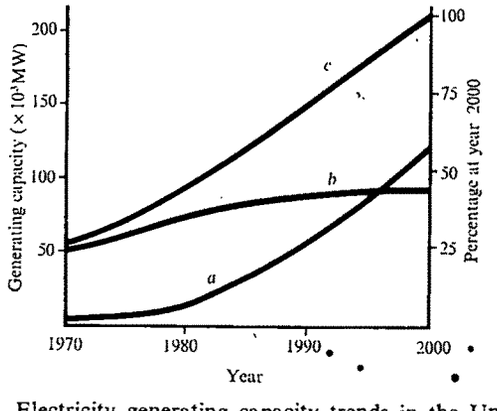

Fig. 3 Electricity generating capacity trends in the United Kingdom. *a*, Nuclear; *b*, fossil; *c*, total.

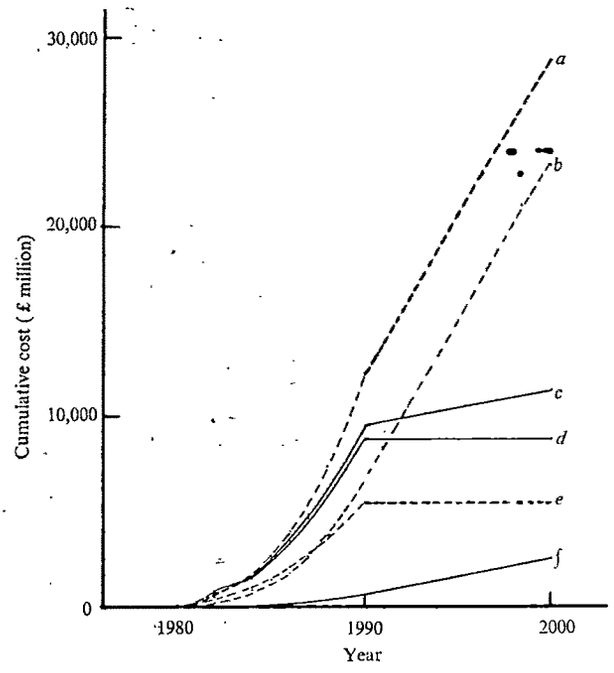

Fig. 4 Cumulative costs of alternative nuclear and fossil programmes completed between 1980 and 1990. *a*, Oil station plus oil; *b*, oil; *c*, nuclear station plus fuel; *d*, nuclear capital; *e*, oil capital; *f*, nuclear fuel replacement. This assumes that the cost of nuclear stations is £240 per kW (including the initial fuel charge); the cost of oil stations is £150 per kW; uranium costs about £6 per pound weight of U_3O_8; oil costs £30 per ton; there will be load factor of 70%; and a 10-yr programme supplying 37,000 MW of energy.

In 1955, when "A Programme of Nuclear Power" was announced in a White Paper, there was no doubt that the gas-cooled, graphite moderated, thermal neutron reactor, based on the Calder Hall, Magnox clad, natural uranium fuelled design, should be the first to be exploited commercially in Britain. During the 1960s, 18 reactors and associated plant in 9 stations were brought into operation (Fig. 6), providing an output of 5,000 MW. It was recognised then that other nuclear options would have to be taken before long, as it was expected that improved models would be built, and that a second type of reactor, liquid-cooled, might be used. So it turned out.

Following Hintonian guidelines to increase temperatures and efficiency and cut costs, the research and development design work was implemented during 1957–58 to enable the construction of an Advanced Gas-cooled Reactor at Windscale (WAGR). In order to limit expenditure its output was set at 35 MW of electricity, which it was believed would be sufficient to allow the core design to serve primarily as a test bed for higher rated, higher temperature uranium oxide fuel, slightly enriched in the more fissile ^{235}U isotope. It was also intended to provide data on the interaction between the graphite, the carbon dioxide coolant and the fuel, later determined as stainless steel clad, under onerous operating conditions. Since 1963, WAGR has been a prolific supplier of invaluable data for Britain's nuclear design teams. Yet it

has given a load factor averaging 84%, remarkable for a prototype plant.

The government, however, was prudently cautious in 1964 when considering the nuclear options for "The Second Nuclear Power Programme". As had been anticipated, other reactors had become available. These could use uranium more efficiently, and could reduce the capital cost of the power station and fuel to a lower level than had proved possible with the alternative Magnox (Mark 1) gas-cooled reactor designs. So tenders from British industry (in some cases including design features from foreign companies)

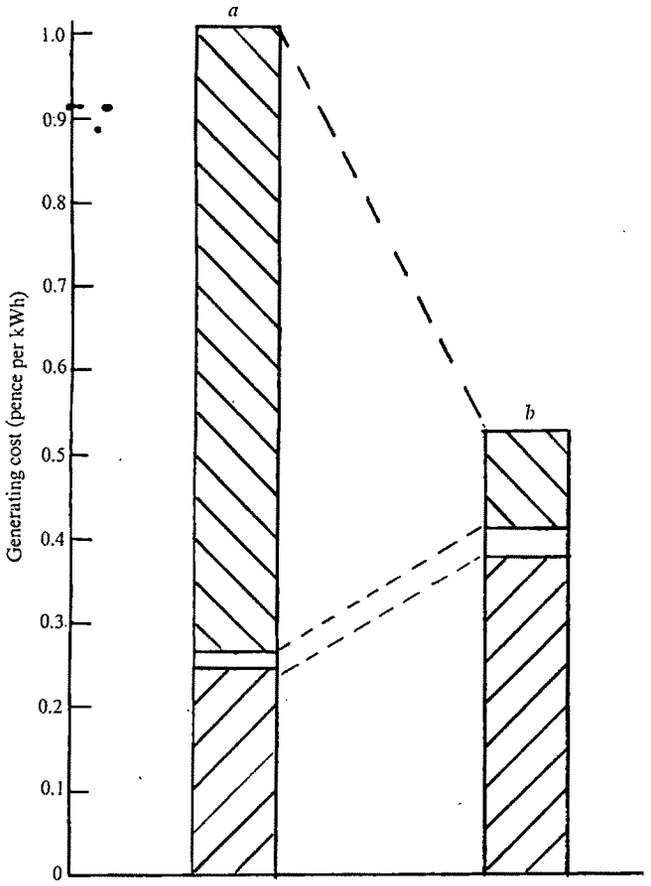

Fig. 5 Electricity generating costs in the United Kingdom. *a*, Oil; *b*, nuclear. In both columns the upper section represents the cost of fuel, and the lower section represents the capital outlay. The space separating the upper and lower sections represents the operational costs.

were considered, and an AGR (Mark 2) design was selected. The background of the assessment and the reasons for the choice were given in special Central Electricity Generating Board publications. A light water reactor design of boiling water type (BWR) was placed second, with pressurised water (PWR) and other AGR designs as runners up.

As a result of this, ten AGRs in five stations were ordered, to provide some 6,000 MW of output. The first two are now almost in operation. Though several PWR and BWR designs have been built more quickly overseas, many have suffered delays and extra costs. The AGRs use a steel cable prestressed concrete pressure vessel, an important safety development which was introduced into the last two Magnox stations. These have always been recognised as safe near urban locations. The LWRs of both kinds, however, have become the centre of a nuclear safety controversy in the United States.

The recent debate in the House of Commons, did not give a definite indication of the government's intentions in deciding between the wider range of nuclear options. Although the debate extended from mid-afternoon until late evening, nuclear power is a non-party issue, and the day was Thursday (with a quiet Parliamentary Friday to follow) and so only about 50 'specialist' MPs attended and there was no sensational result. There was, however, strong support for the British reactor designs and it was agreed that whatever decision was finally reached, any reactor built in the near future must be safe.

No one in the nuclear industry, Parliament, the Nuclear Power Advisory Board or the government seems to doubt that the development of a high temperature gas-cooled reactor (HTR) will eventually be a sensible course of action. The timing of the construction of the first commercial station, in relation to the progress of development work in the Euratom Dragon project and to advances overseas (not least in the USA) has yet to be settled. It seems unlikely, however, that the first, large, Mark 3 gas-cooled reactor unit could be ordered soon, which means that such designs will not contribute to commercial nuclear power until the late 1980s. Bearing in mind the continuing need for the improvement of designs using ceramic particle fuel and higher temperature coolant circuits (which have helium instead of carbon dioxide) this is a project which would suffer if rushed. On the other hand, the longer term development potential of the HTR could usefully receive more effort. Ideas for using HTRs to generate electricity with gas turbines, and the application of HTRs to provide process heat, now seem to be moving ahead more quickly as collaboration with other countries is arranged.

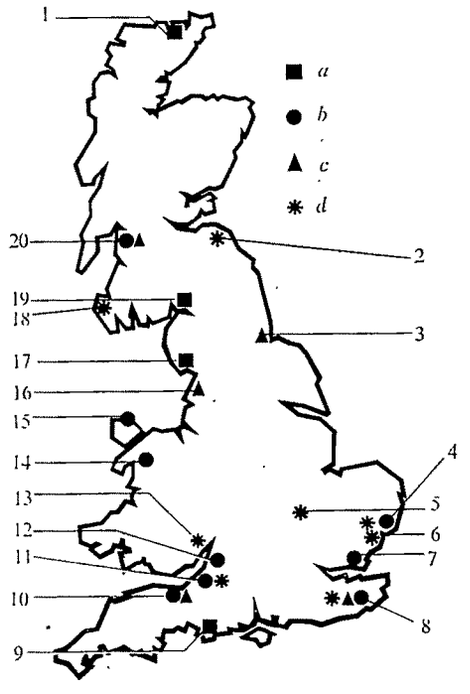

Fig. 6 Nuclear power in Britain. *a*, Experimental power stations; *b*, Magnox stations; *c*, AGR stations under construction; *d*, proposed stations. 1, Dounreay DFR and PFR; 2, Dunbar; 3, Hartlepool; 4, Sizewell 'A' and 'B'; 5, Molesworth; 6, Orfordness; 7, Bradwell; 8, Dungeness 'A', 'B' and 'C'; 9, Winfrith 'Dragon' and SGHWR; 10, Hinkley Point 'A' and 'B'; 11, Oldbury 'A' and 'B'; 12, Berkeley; 13, Portskewett; 14, Trawsfynydd; 15, Wylfa; 16, Heysham, 17, Calder Hall and Windscale Magnox and AGR; 18, Girvan; 19, Chapelcross Magnox; 20, Hunterston 'A' and 'B'.

The declared reluctance in some parts of the Central Electricity Generating Board to order more AGRs, can be expected to decrease as experience is gained with Hinkley Point B station and the South of Scotland Electricity Board's Hunterston B station. Both of these stations

are now almost in operation. Meanwhile, although forecasters have been perturbed by the low electricity demand of the past winter, it is felt that one or two stations of some other kind must be ordered soon to supplement firm power supplies in the early 1980s.

The case for building LWRs designed in the United States (particularly the PWR) in the meantime, has been strongly pressed by senior people in the CEGB and the National Nuclear Corporation (NNC)—a potential supplier under licence. Doubts that have arisen concern the safety of the thick steel pressure vessels and the pipework which comprise the coolant circuit, and the effectiveness of the emergency core cooling system (ECCS) in the event of a major fracture of the circuit. Much experimental work has yet to be done in the USA and other countries using LWRs, on both pressure vessel failure and ECCS during the next few years. There has been no publication of convincing evidence that, even if satisfactory safety solutions were known, any programme including the PWR would be better or cheaper than a programme using the British design. Factors bound to lengthen the programme and increase the costs are: import requirements, searching Electricity Board specifications, and the necessary quality assurance standards. It is important to avoid delays. For a large nuclear station, the interest charges on the committed capital, and the cost of alternative electricity supply into the grid system, can be of the order of 7% of the cost of the station for each month of delay. About 15 months of delay will double the cost. Project management and realistic construction programme planning are factors which are as important as plant design if improvement on past experience is to be obtained.

The case for building the British steam generating heavy water moderated reactor design (SGHWR) has been strongly pressed by the South of Scotland Electricity Generating Board and the Parliamentary Select Committee. The prototype 100 MW SGHWR power station which has been operating at Winfrith Heath in Britain since 1968, has resulted in an improved understanding of water reactors. The prototype incorporates many attractive features selected from the best of the earlier reactors. Not least of these is the modular pressure-tube construction of the core, avoiding the thick steel pressure vessel which characterises the LWRs. Experience in the operation of the Winfrith SGHWR has been good so that larger stations could now be built, with or without support from similar pressure tube reactor work in Canada, on the CANDU and boiling light water types. As in the case of the LWRs, however, many power station engineers consider that it is a retrograde step back to saturated steam conditions for the turbine-generators, particularly as the superheat steam machines now in use in all advanced British base-load power stations would be needed again later in the programme. It is possible, however, that because of the amount of nuclear power needed in Britain, there may be room for a few SGHWR designs. Interested countries abroad would then have some indication of the effectiveness of the design in larger scale operation than has been possible at Winfrith Heath.

In due course, fast neutron breeder reactors will be needed to ensure the better use of uranium resources. By converting ^{238}U (or ^{232}Th) into the more fissile ^{239}Pu (or ^{233}U) they can enable possibly a 50 fold reduction in uranium needs. They can also use waste ^{238}U from earlier isotope and uranium-plutonium separation plant operations, and ensure that natural uranium continues to be available at acceptable prices for the thermal reactors still operating.

Encouraging progress towards commercial sodium breeders is now becoming apparent, with the French Phenix and British PFR in operation. Only three factors could delay the establishment of commercial lead stations in continental Europe and Britain in the early 1980s: first, the inability to demonstrate that a programme of such reactors could be built with capital costs low enough to allow electricity to be generated as cheaply as is possible using contemporary thermal reactors: second, poor explanation to the public of the exceptional value of plutonium as a 'perpetual motion' fuel; and finally, poor explanation to the public of ways that plutonium can be managed in the fuel cycle external to the reactors.

Gas-cooled breeder designs would have been much further advanced if at the time of initial consideration prestressed concrete vessels had been available to ensure safe designs, which steel vessels could not. Gas-cooled reactors would have been a logical next step beyond the AGR and HTR. While a European Gas Breeder Reactor Association is now pursuing limited objectives in the fuel design and plant layout areas, large scale expenditures are unlikely, and progress is likely to be slow as long as success with sodium-cooled breeder reactors remains a possibility.

Probable strategy

The basis of probable future strategy (Table 2) is that gas-cooled reactors of the Magnox (Mark 1) type have worked well and given invaluable experience for later developments. It can be expected that gas-cooled reactors of the AGR (Mark 2) type will soon begin to work well and that the difficult problems of the earlier designs can be avoided through more careful specification of plant yet to be ordered, particularly concerning the boilers and the insulation of pressure vessel liner. It is agreed that development work towards gas-cooled reactors of the HTR (Mark 3) type should be continued because of its potential for electricity and process heat applications. Thus, gas breeder reactors (Mark 4) could be achieved, which in a large-scale, fusionless, national energy system of the distant future might have a place complementary to, or even supplanting, the most advanced sodium breeder reactors. They would not operate, however, before 1995.

A further basis of this strategy is that if water-cooled reactors are required, it will only be to a very limited extent, and there is not a justifiable case for importing their technology into the PWR or BWR designs at considerable cost. Proving their safety would give continuing difficulty in Britain. Sufficient progress has been made with the British SGHWR to exploit its capability now commercially in a few larger stations, while the AGR matures to full credence. An alliance of British SGHWR and Canadian knowledge with similar plant should mean that some overseas customers will become confident enough to order water-cooled power stations from the combined organisation. This might not occur if Britain and Canada continue to operate separately.

It does not ease the problems of a country to have too many parallel lines of development simultaneously. In particular, it is not beneficial to build contemporaneously too many prototype or lead power stations. With the choice of gas-cooling as the main line, and sodium-cooling as an option for the future, Britain would seem to have sufficient scope but not excessive problems. If there are benefits from water-cooled designs, as there seem to be in the small sized unit overseas market, these will come with slight extension of present commitments through SGHWRs. That obviates the greater effort required to understand and necessarily improve the LWR technology by importing PWR designs. Britain could and should buy technological expertise from abroad when it is lacking at home, but in the nuclear power field this is unnecessary at the present time. Indeed, she has available to other countries valuable gas-cooled, water-cooled and sodium-cooled reactor technology, which improved marketing could turn to benefit.

DNA fragments carrying genes for $tRNA^{Tyr}_{I}$

Arthur Landy, Carl Foeller & Wilma Ross

Division of Biological and Medical Sciences, Section of Microbiology and Molecular Biology, Brown University, Providence, Rhode Island 02912

The duplicated genes coding for $tRNA^{Tyr}_{I}$ have been isolated using site-specific nucleases and gel electrophoresis. An unduplicated sequence of 4–120 base pairs separates the two genes. Specific DNA fragments can be obtained in sizes appropriate for both functional and structural analysis of the $tRNA^{Tyr}_{I}$ region.

ONE approach to studying the detailed structure of a transfer RNA gene involves the chemical synthesis of the relevant deoxyribonucleotide sequences[1]. A major barrier to alternative approaches has been the problem of isolating genomic sequences of the appropriate size and purity. Several preparations of DNA enriched to various degrees for regions complementary to transfer RNA have been described[2–5]. In the experiments reported here, the genes for $tRNA^{Tyr}_{I}$ have been obtained as small DNA fragments using a combination of several site-specific endodeoxyribonucleases and polyacrylamide-agarose gel electrophoresis[6,7].

In *Escherichia coli*, three genes for $tRNA^{Tyr}$ have been identified. The gene coding for the major species, $tRNA^{Tyr}_{II}$, (70% of the total tyrosine accepting activity), maps at approximately 78 min (refs 8–10). The two genes which code for the minor species, $tRNA^{Tyr}_{I}$, occur as a duplication near the attachment site for bacteriophage Φ80 (refs 11–13). (The term gene is used here to indicate that sequence of bases coding for each tRNA. There is no evidence at present to indicate whether the two $tRNA^{Tyr}_{I}$ genes are transcribed as a single RNA molecule, as is found for tRNAs coded by bacteriophage T4 (ref. 14).) The $tRNA^{Tyr}_{I}$ genes are only distinguishable from one another in su $^{+}_{III}$ cells where one of them has a single base change in the anticodon region[15,16]. This suppressor phenotype has made possible the isolation of several different transducing derivatives of bacteriophage Φ80 as well as the isolation and biochemical characterisation of mutants deficient in various aspects of tRNA function[17–19].

Three phages have been used as sources of DNA. The phage Φ80h psu $^{+}_{III}$ (double copy phage or 'doublet') is a nondefective transducing phage carrying both genes for $tRNA^{Tyr}_{I}$. The phage Φ80h psu$^{+}_{III}$ (single copy phage or 'singlet') is a phage derived from the doublet phage by an unequal recombination event between homologous sequences, such that one of the two $tRNA^{Tyr}$ genes has been eliminated (see Fig. 6, inset). The phage from which the transducing phage were derived is Φ80h amb1 and will simply be referred to as Φ80h or parental[11].

DNA digestion profiles

The site-specific nuclease endo R·*Hin*d, (prepared from *Hemophilus influenzae* Rd according to the procedure of Smith and Wilcox[20]), was used to digest DNA isolated from Φ80h, the doublet transducing phage and the singlet transducing phage. When the limit digestion products are compared by gel electrophoresis, the three profiles are found to be congruent for a majority of the fragments (Fig. 1). Our conclusions here are based upon composite data obtained from the application of several different electrophoretic conditions, each chosen for its ability to resolve optimally a particular group of fragments. To facilitate comparison of the three DNA digests, a schematic diagram combining the data from several electrophoresis conditions is given in Fig. 2. Construction of this composite is accomplished by including an overlap of well resolved fragments in each experiment. The band differences between the three DNAs provide convenient landmarks for confirming the alignment of profiles.

There are three fragments which are unique to Φ80h DNA (A4, A6 and E4). There are five fragments which are absent from the Φ80h digest but which occur in both the singlet and doublet digests (A4a, A6a, D1a, F3a, F3b). These are called transducing-unique. In addition, there is one singlet-unique fragment (C1a) and one doublet-unique fragment (B10a).

Hybridisation

The ability to hybridise with ^{3}H-$tRNA^{Tyr}$ (ref. 21) has been tested for each of the seven fragments unique to the DNA of the transducing phages. These unique bands, and several others which are common to all three phages, were eluted separately from preparative-scale gels. The only fragments showing any significant hybridisation with ^{3}H-tRNA are the

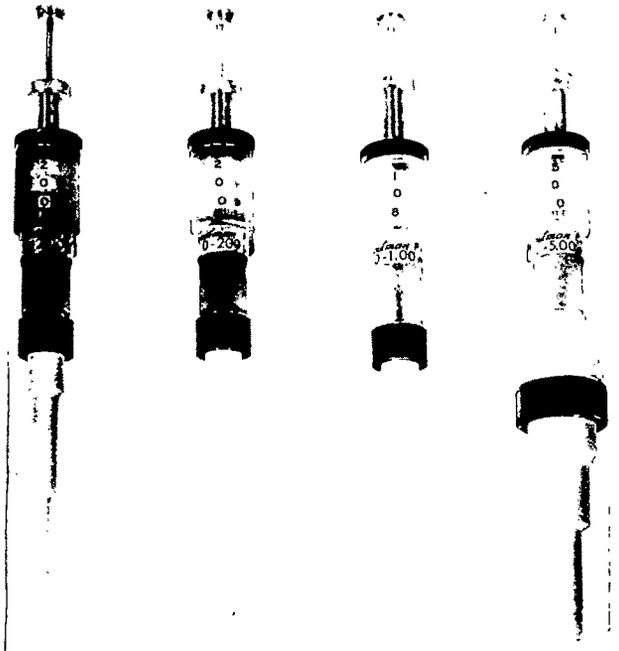
DNA fragments were prepared from ^{32}P-labelled singlet and doublet DNAs (2×10^{3} c.p.m. μg^{-1} at the time of hybridisation) by preparative gel electrophoresis and electroelution from excised gel strips. After phenol extraction and dialysis, DNA was denatured in 0.2 N NaOH at 20° C for 15 min, neutralised with Tris-HCl, and brought to 6×SSC. Fifteen microlitres, containing 27 pmol of fragment were spotted immediately onto a dry 13 mm Millipore filter, which had been prewashed successively in 6×SSC and distilled water. DNA filters were exposed, while still wet, to ultraviolet light at 22 cm from a 15 W GE germicidal lamp (5 min per side), then dried for 3 h at 80° C under vacuum. To remove loosely bound DNA before hybridisation, filters were washed in 6×SSC, 0.1% Sarkosyl for 30 min at 20° C, then for 30 min at 67° C. Hybridisation was carried out in 6×SSC, 0.1% Sarkosyl, with ^{3}H-tRNA (2 μg ml^{-1}) at 67° C for 8 h. The ^{3}H-tRNA preparation was enriched for $tRNA^{Tyr}$ on B-D Cellulose[23]. Following hybridisation, filters were washed, treated with T_1 and pancreatic RNase as described[21], and counted in omnifluor.

SOLID STATE PHYSICS

EXPERIMENTAL APPARATUS FOR TEACHING THE PHYSICAL PROPERTIES OF CRYSTALS



The illustration shows the apparatus for measuring Magnetic Susceptibility — an example from our range which includes experiments on the electical, mechanical, optical, thermal, magnetic, semiconductor, piezo- and pyro-electric properties of crystals.

Introduction or extension of student courses is facilitated by the availability of the text book 'Experimental Crystal Physics' by Dr W. A. Wooster and Professor A. Breton and the comprehensive laboratory notes supplied with the apparatus.

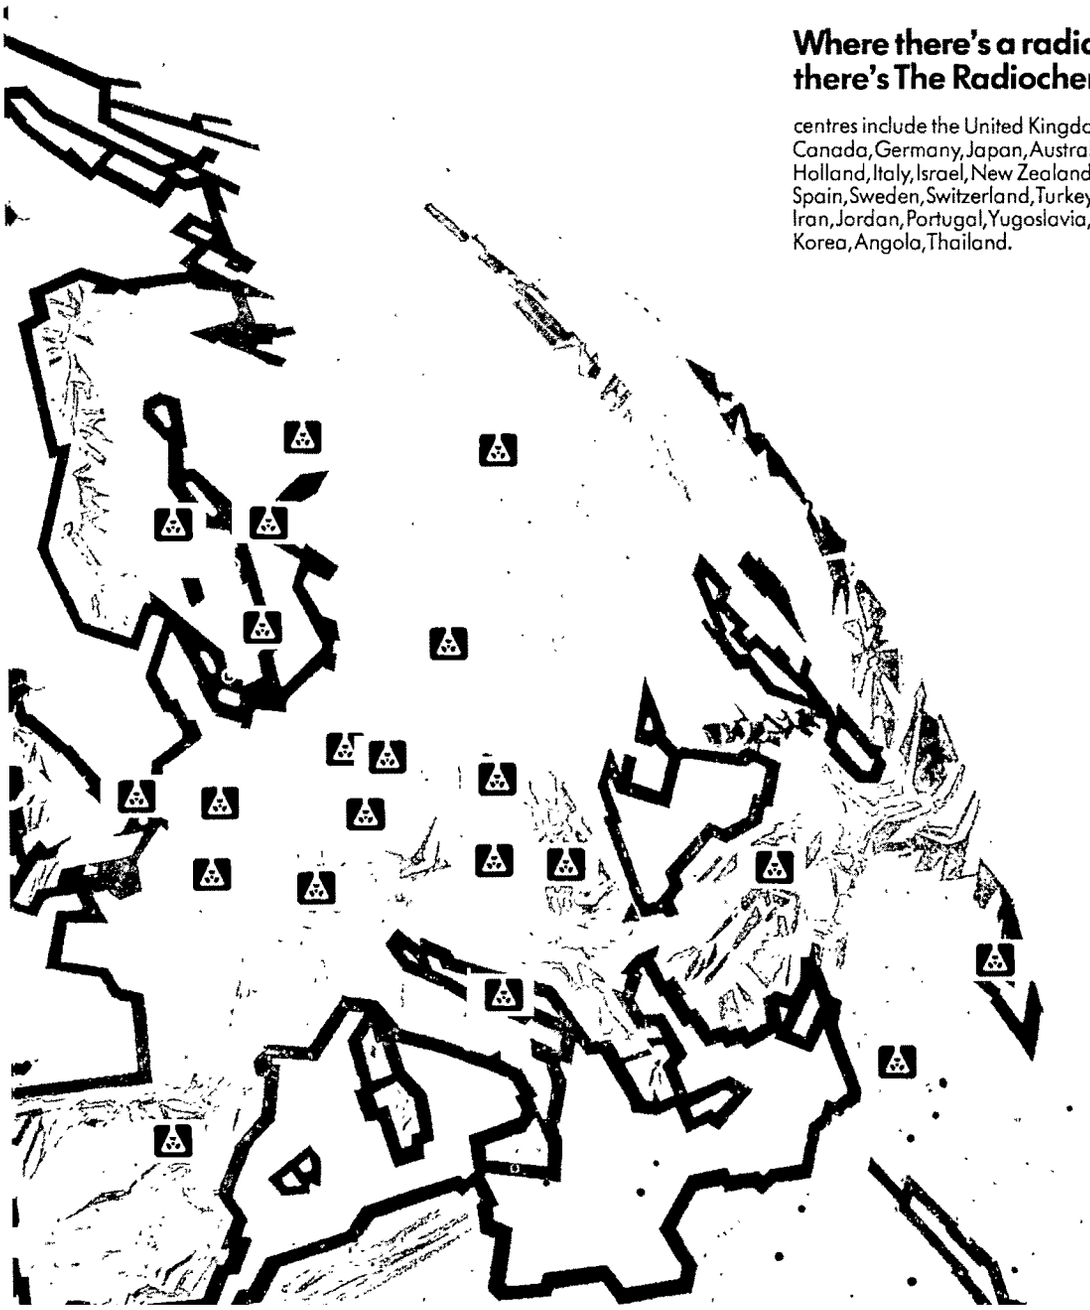
The Radio

hemical Centres

We concentrate on being a truly international operation; our two associate companies and 30 distributors form the largest and most widespread radiochemical network in the world. Both associates, and some of the regional agencies, carry their own stocks, and all are fully geared to provide first class delivery, servicing and on-the-spot technical advice.



Our technical customer liaison rests firmly in the hands of highly qualified scientists who are as familiar with the applications of our products as with their capabilities, and are as conversant with new research techniques as with established procedures.

Our customer service teams always provide prompt technical advice, and our most experienced scientists will often visit your laboratories to discuss particular problems in the use of radiochemicals.

Further information on our research radiochemicals service is available from your local distributor–please write to us for his name and address.

Reactive Free Radicals

J. M. HAY

June 1974, viii+162pp., £4.40/$11.50 0.12.3335507

In this work the author has aimed to relate the reactivity of organic free radicals to their structure, and in particular to the type of orbitals occupied by their unpaired electrons. The treatment is more systematic than in previous publications.

Contents

Introduction. The structure of radicals. Bond dissociation energies. The formation and reactivity of radicals: non-polar effects. The formation and reactivity of radicals: polar effects. Autho index. Subject index.

Sub-Clinical Lead Poisoning

H. A. WALDRON and D. STOFEN

April 1974, xx+224pp., £5.50/$15.50
0.12.671650.1

Sub-clinical lead poisoning is a relatively new concept and to some extent a controversial one. This book aims to provide a broad and objective assessment of the information currently available, including work carried out in eastern Europe where the problem has been considered for longer than in the rest of the world. Accounts of the metabolism and pathology of lead in man and other animals, the signs and symptoms of classical clinical lead poisoning and the mobilisation of lead by man in historical and recent times, are given as background to the main study.

Parenteral Nutrition in Acute Metabolic Illness

edited by H. A. LEE

July 1974, xiv+454pp., £9.00/$23.25
0.12.441750.7

Here is an up-to-date account of the pharmacological, biochemical and clinical advances in the field of parenteral nutrition, which will be of prime importance to everyone involved in the management of "intensive care" patients, whether at clinical or laboratory level.

Contents

Introduction. Basic facts and requirements for intravenous nutrition. Physiopathology or injury. Clinical applications. Techniques and solutions. Studies of tolerance and toxicity. Author index. Subject index.

Microprobe Analysis as Applied to Cells and Tissues

edited by T. HALL, P. ECHLIN and R. KAUFMANN

June 1974, xx+435pp., £7.80/$20.25
0.12.319050.9

The present work consists mainly of papers presented at a conference on Microprobe Analysis as applied to Cells and Tissues held at the Battelle Seattle Research Center, Washington, USA during April and May, 1973. The papers explain and illustrate how microprobe techniques may be exploited to the limit of their present capability, and explore in detail the main technical problems, especially those of specimen preparation and of beam-induced damage in electronprobe microanalysis. Each presentation is concluded by a critical appraisal of the topic under discussion.

The Biochemical Mode of Action of Pesticides

J. R. CORBETT

June 1974, x+330pp., £7.20/$20.25
0.12.187850.3

This book provides a completely novel synthesis of current knowledge of how pesticides act at the molecular level. All fungicides, herbicides, insecticides and some veterinary products now in use, as well as some now superceded, but of special biochemical interest, are considered according to their mode of action. Information on uptake and breakdown is included where it is relevant to this underlying theme. Unlike most works in the field this text does not deal with fungicides, herbicides and insecticides separately. Rather the author considers it biochemically more logical to treat the compounds according to their molecular action, so highlighting relationships and common features and providing some explanation of selective toxicity.

For a descriptive leaflet on any of the above journals, please write to the publishers.

singlet-unique fragment, C1a, and the doublet-unique fragment, B10a (Table 1). There is occasionally a small amount of hybridisation observed in the bands immediately adjacent to C1a and B10a which is an artefact encountered in slicing the preparative gels and eluting bands. For example in Table 1 band B8,9 shows some evidence of hybridisation in doublet DNA where it is adjacent to B10a; however, in singlet DNA which contains C1a instead of B10a, the B8,9 band does not show any hybridisation.

The strongest statement permitted by the limitations inherent in the hybridisation experiment is that a particular fragment does carry a significant portion of the $tRNA^{Tyr}$ gene. It cannot be ruled out, on the basis of these experiments alone, that some other fragment(s) may also carry a portion of the $tRNA^{Tyr}$ gene which is either too small to be detected in the assay or which codes for those precursor sequences not found in the mature tRNA (ref. 22).

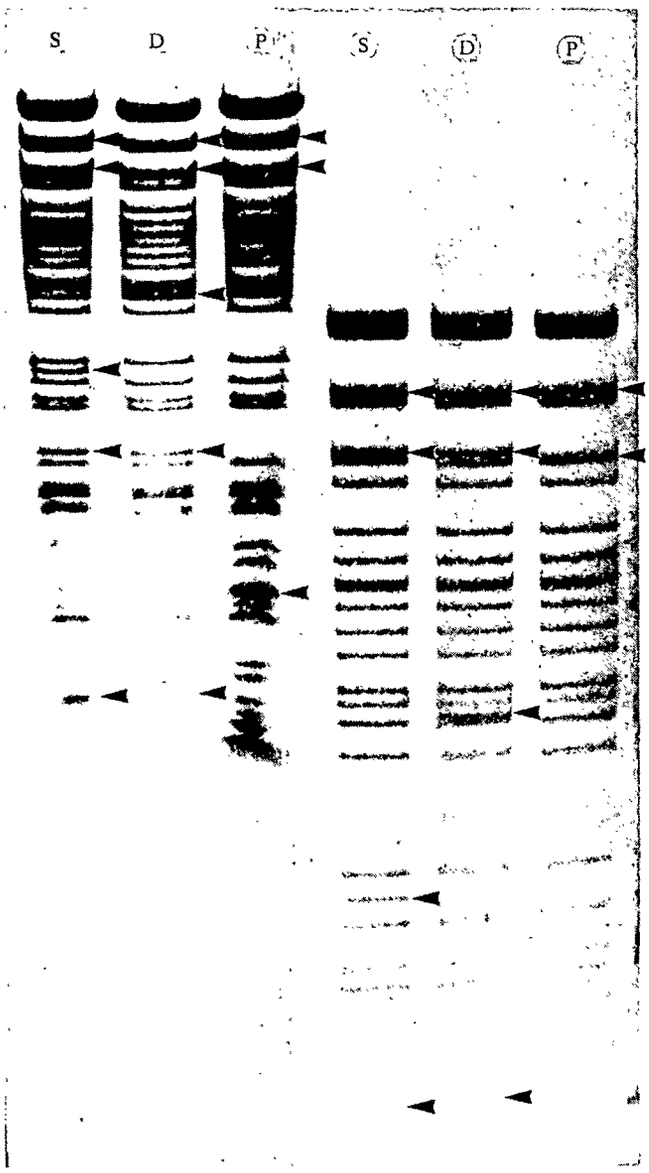

Fig. 1 Digestion profiles of Φ80h, doublet and singlet DNA produced by endo R·*Hin*d. Growth of phage and preparation of DNA were as described previously[23]. All endonuclease digestions were carried out for 4.5 h at 37° C in 10 mM Tris–Cl (*p*H 7.9), 6.6 mM $MgCl_2$, 6.6 mM mercaptoethanol, 60 mM NaCl with DNA at 200 μg ml^{-1} and using amounts of endonuclease sufficient to yield limit profiles. Unless specified otherwise all gels were made and run in Tris-Borate buffer (*p*H 8.3), have the composition 2% acrylamide (0.1% N, N′-methylene-bis-acrylamide), 0.5% agarose and were stained with Stains-all[7]. Electrophoresis was carried out at 200 V (11 V cm^{-1}) in EC apparatus flat plate cells cooled to 4° C. Digestions of Φ80h (P), doublet (D), and singlet (S) DNA were divided into two aliquots; lanes 1–3 each contain 40 μg of DNA and were electrophoresed for 3 h; lanes 4–6 each contain 10 μg of DNA and were electrophoresed for 6 h. Unique fragments (those not common to all three) are indicated by arrowheads (see text). For identification of the unique fragments see Fig. 2.

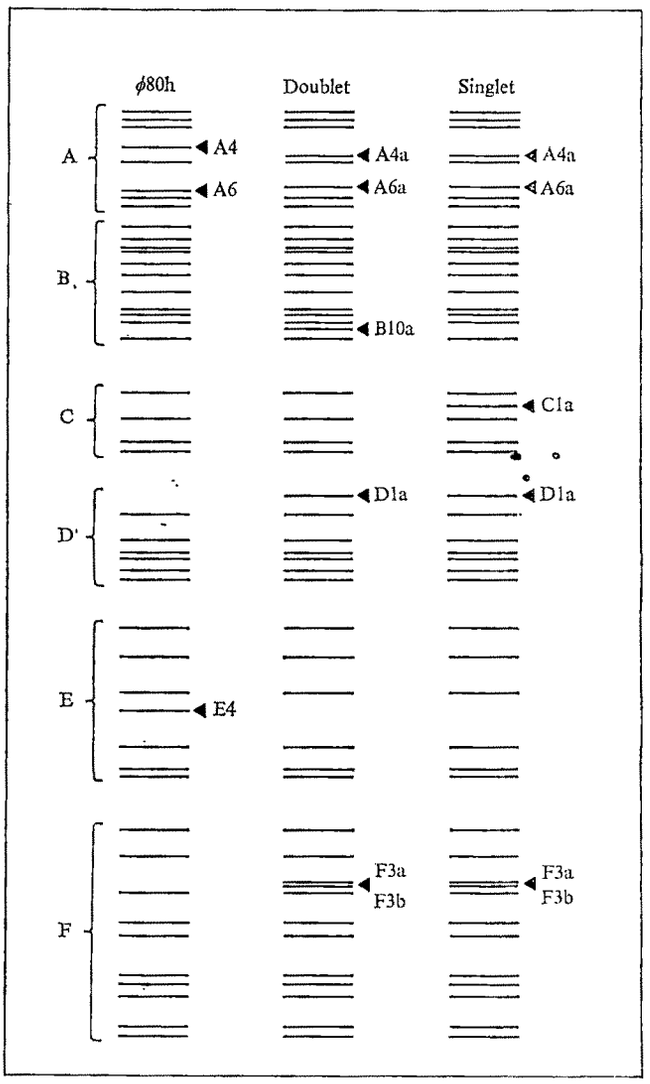

Fig. 2 Schematic diagram of *Hin*d digestion profiles of Φ80h, doublet and singlet DNAs. The relative migration distances are based on a 2% acrylamide–0.5% agarose 45 cm gel profile. Arrowheads indicate those bands unique to one or two DNAs (compare with Fig. 1). Band nomenclature is based upon the Φ80h profile. Bands falling into visually separated groups are assigned letters A–F, and fragments within a group are assigned consecutive numbers in order of migration distance. Labels for the fragments unique to singlet and/or doublet DNA are derived from the nearest non-unique fragment by the addition of a small letter (see ref. 23).

Integrity of $tRNA_1^{Tyr}$ genes

The question of whether all the sequences coding for the mature $tRNA_1^{Tyr}$ reside on the singlet-unique (C1a) and doublet-unique (B10a) fragments can be restated. Is there a nuclease recognition site within the tRNA gene(s) (including, in the case of the doublet DNA, any unduplicated intergenic region)? The following analysis is based upon two assumptions. First, the generation of the single copy transducing phage from the double copy transducing phage was by a mechanism not more complex than that deduced from the genetic data (ref. 11 and Fig. 6 inset). Second, if a nuclease-sensitive site exists in one region specifying $tRNA_1^{Tyr}$ it also exists in the other[16].

The distribution of fragments unique to each of the phage DNA digestions sheds some light on this question. The

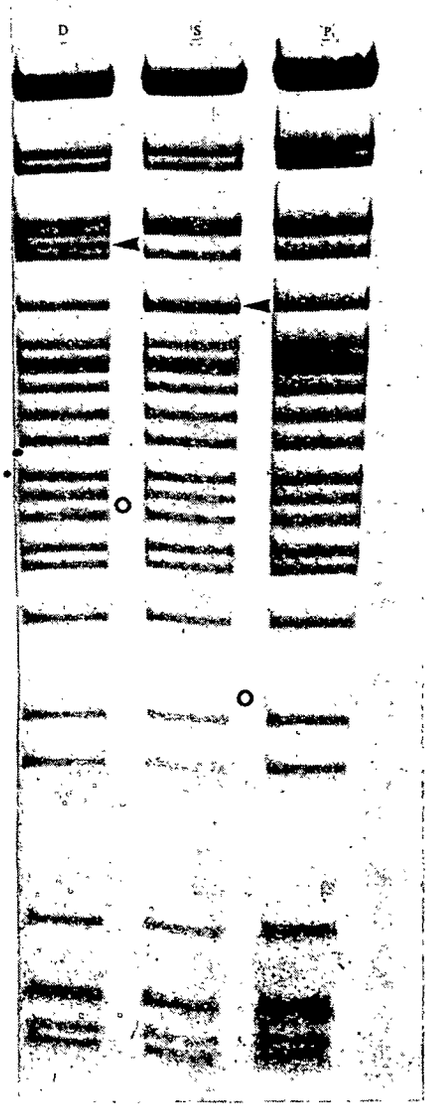

Fig. 3 Digestion profiles of Φ80h, doublet and singlet DNA produced by endo R·*Hin*c. Endo R·*Hin*c, purified from *Hemophilus influenzae* Rc (23) was used to obtain limit digestions of Φ80h (P), doublet (D) and singlet (S) DNA. Conditions of digestion and electrophoresis were as described in Fig. 1 except that electrophoresis was for 5 h. The *Hin*cII and *Hin*d (*Hin*dII and *Hin*dIII) digestion profiles of Φ80h DNA are identical except for four fragments unique to *Hin*cII and eight fragments unique to *Hin*d (ref. 23). Fragments unique to the *Hin*cII digestion are named for the nearest *Hin*d fragment followed by a small letter suffix. Arrowheads indicate the *Hin*cII doublet-unique (A7a) and singlet-unique (B1a) fragments which carry the $tRNA_1^{Tyr}$ gene(s). (In these gel electrophoresis conditions, B1a is not resolved from B1.) ○, Positions of the *Hin*d $tRNA_1^{Tyr}$ containing fragments, B10a and C1a—missing in a *Hin*cII digestion profile.

existence of three Φ80h unique fragments is a consequence of two nuclease recognition sites which exist in Φ80h DNA but which are missing from the DNA of both transducing phages. In the transducing phages the segment of *E. coli* DNA has brought into the phage genome five nuclease-sensitive sites generating the six unique fragments in each phage. The conclusion that none of these five nuclease-sensitive sites is within the $tRNA_1^{Tyr}$ gene(s) derives from the fact that the singlet and doublet DNA digestions have the same number of fragments. If there were a nuclease-sensitive site anywhere within or between the duplicated sequences, then the number of unique bands in the doublet DNA would be one greater than the number in the singlet DNA and the ability to hybridise ^3H-$tRNA_1^{Tyr}$ would have to reside in a band common to both phages.

Endo R·*Hin*d (the phosphocellulose fraction of *H. influenzae* Rd) contains two ATP-independent nuclease activities each specific for a different deoxyribonucleotide sequence (ref. 23 and H. Smith, personal communication). The nucleotide recognition sequence of the two enzymes, *Hin*dII and *Hin*dIII, have been determined using T7 DNA (ref. 24) and λ DNA (K. Murray, personal communication) respectively. The fact that neither of the nucleotide sequences recognised by these two enzymes is contained in the sequence of $tRNA_1^{Tyr}$ (ref. 16) or in the known tRNA precursor sequence[22] is consistent with the conclusion that no *Hin*d nuclease cuts are made within the duplicated $tRNA_1^{Tyr}$ gene sequences.

Hemophilus influenzae strain Rc contains a nuclease, *Hin*cII, with a specificity identical to that of *Hin*dII, but lacks any activity corresponding to the *Hin*dIII enzyme[23]. Therefore, those *Hin*d fragments produced by a *Hin*dIII cut at one or both termini are not present in a *Hin*cII digestion profile but occur as part of some larger, *Hin*cII-unique, fragment. The *Hin*d fragments B10a (doublet-unique) and C1a (singlet-unique) are in this category, and the fragments containing these sequences in a *Hin*cII digest are A7a and B1a respectively (Figs 1 and 3). These are the only doublet-unique and singlet-unique fragments in a *Hin*cII digest and have the same molecular weight difference as B10a and C1a (Table 2).

When the *Hin*cII fragment A7a is eluted and digested with Rd enzyme it gives rise to the *Hin*d fragments B10a, D1a, F3a, and F3b; whereas, the *Hin*cII fragment B1a gives rise to the *Hin*d fragments C1a, D1a, F3a, and F3b (A.L., C.F., and W.R., unpublished) (compare Figs 2, 3, and Table 2). These results further strengthen the conclusion that the fragments B10a and C1a originate from homologous regions in their respective chromosomes, and that they differ from each other only by that piece of DNA which was lost in the genetic derivation of the singlet from the doublet transducing phage (Fig. 6).

tRNA gene size

Although the full size of the $tRNA_1^{Tyr}$ precursor molecule has not yet been established, the presently known sequences require a minimum of 128 base pairs for the $tRNA_1^{Tyr}$ gene[22]. In further experiments a $tRNA_1^{Tyr}$ precursor 135–140 bases long has been observed (S. Altman, personal communication).

On the basis of the molecular weight difference between the doublet-unique fragment B10a and the singlet-unique fragment C1a (Fig. 4 and Table 2) it is estimated that the size of one $tRNA_1^{Tyr}$ gene plus any unduplicated intergenic sequence is approximately 200–260 base pairs. This number is somewhat larger than the size, 90–150 base pairs, estimated by electron microscopy of intact heteroduplex DNA molecules[25,26]. Estimates such as these represent an upper size limit, as the region of genetic duplication could be larger than the tRNA genes. If the crossover in the recombination event which

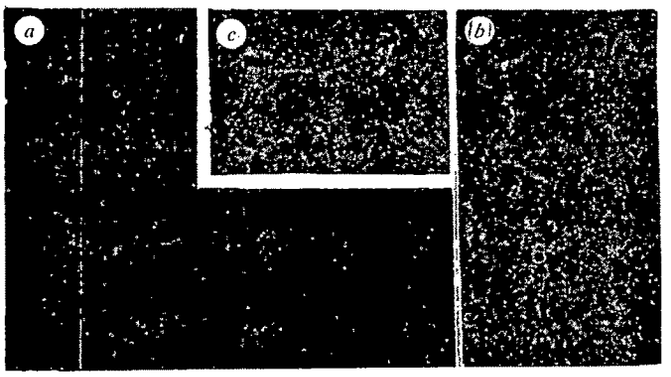

Fig. 4 Electron micrographs of (*a*) doublet-unique (B10a) and (*b*), singlet-unique (C1a) fragments. DNA fragments were prepared as described in Table 1. ΦX174 RFII circles, (*c*) (molecular weight 3.4×10^6 daltons) were included as internal standards for the contour length determination of fragment size. The electron micrographs were made by Nancy Brimlow in the laboratory of David Freifelder[28].

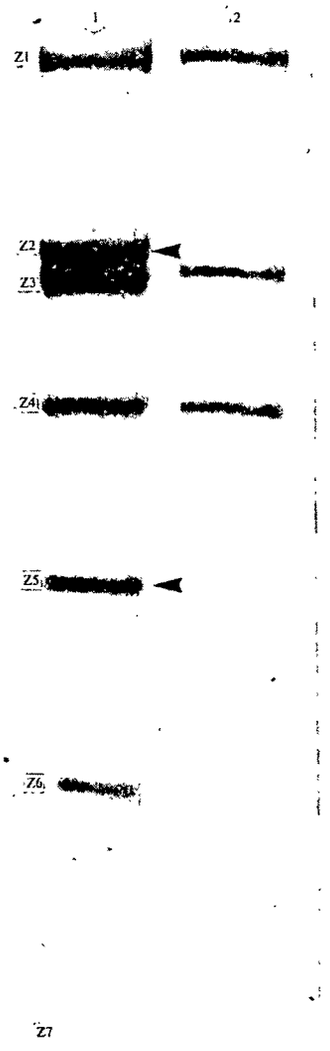

Fig. 5 Digestion of the doublet-unique (B10a) and singlet-unique (C1a) fragments with endo R·*Hae*. Endo R·*Hae* was prepared from *Hemophilus aegyptius* as described by Middleton *et al.*[27]. Pure singlet-unique fragment C1a was prepared as described in Table 1. B10a was obtained free from contamination by neighbouring fragments by isolating the *Hin*cII doublet-unique fragment A7a, digesting it with endo R·*Hin*d, and electrophoresing the digest to obtain the pure B10a product. Fragment B10a (lane 1) and fragment C1a (lane 2) were digested with endo R·*Hae* using the same digestion conditions as described in Fig. 1, and electrophoresed in a 5%–0.5% acrylamide-agarose gel for 3 h at 300 V. Fragments derived from B10a are numbered consecutively Z1–Z7. Fragments derived from C1a are assigned the number of the homologous fragment derived from B10a. Arrows indicate those fragments derived only from B10a: Z2 and Z5.

generated singlet from doublet took place outside the limits of the tRNA genes, then the doublet phage and singlet phage would differ by a correspondingly greater number of base pairs. This question will be answered in the course of the nucleotide sequence analysis of this region.

Taking the size of the tRNA gene plus spacer to be approximately 150×10^3 daltons (Table 2), the doublet-unique B10a and singlet-unique C1a fragments are two to three times the absolute minimum size necessary to contain the genomic regions coding for $tRNA_1^{Tyr}$.

To obtain a subset of smaller $tRNA_1^{Tyr}$ gene fragments, purified doublet-unique fragment (B10a) and singlet-unique fragment (C1a) were digested with endo R·*Hae* (from *H. aegyptius*) (ref. 27). The resulting fragments are well resolved on 5% gels (Fig. 5). Five of the seven fragments derived from the doublet genome have mobilities identical to those of the five fragments from the singlet genome. At the observed level of resolution this degree of coincidence can be taken as strong evidence (that is, as a fingerprint) that the two parental molecules, B10a and C1a, possess large regions of identical sequence.

Table 2 shows that, within experimental error, the molecular

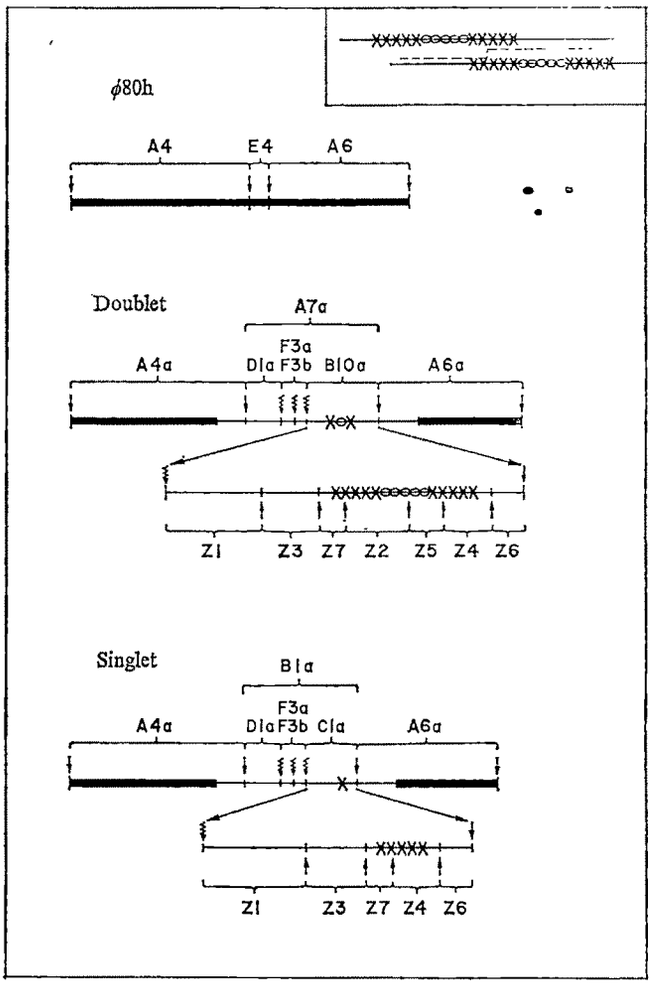

Fig. 6 A model, relating the fragments produced by *Hin*dIII, *Hin*cII and *Hae* nucleases. Homologous segments of the three phage genomes Φ80h, doublet and singlet are shown: phage DNA (▬), *E. coli* DNA (———), *E. coli* DNA duplicated in doublet phage and containing $tRNA_1^{Tyr}$ sequences (—X—), *E. coli* DNA found only in doublet phage, that is, nonduplicated intergenic sequences (—0—). The cleavage sites of the three different enzymes are marked: *Hin*cII or *Hin*dII (↓), *Hin*dIII (⇓), *Hae* (↑). The DNA fragments are labelled and drawn to the same relative scale, or expanded 5 times, as indicated (for assigned molecular weight values see Table 2). Of the four fragments derived from the *Hin*cII fragments A7a (doublet) or B1a (singlet), F3a and F3b are the only two which appear in a digest of intact singlet or doublet DNA with *Hin*dIII enzyme and must therefore be internal. As Z2 and Z5 are the only *Hae* fragments unique to doublet DNA, they must be adjacent and include all of the unduplicated intergenic sequence (—0—). (If there were no *Hae* sites in the unduplicated intergenic region only one doublet-unique fragment would be generated; two *Hae* sites in this region would give rise to three doublet-unique fragments, and so on.) The relative order of the other fragments is not determined nor is the location of the juncture between *E. coli* DNA and phage DNA. The size of each of the regions marked by (—X—) (the duplicated sequence) is between 135 and 230 base pairs and the size of the unduplicated sequence between them (—0—) is between 4 and 125 base pairs (see text). Inset: a representation of the out-of-register mispairing between identical doublet chromosomes, and an unequal recombination event (– – –) which gives rise to the singlet chromosome (ref. 11).

Table 2 Molecular weights of 'unique' fragments from $tRNA_I^{Tyr}$ region

*Hin*cII fragments	Phage derived from	Molecular weight (daltons × 10^{-5})	*Hin*d fragments	Phage derived from	Molecular weight (daltons × 10^{-6})	*Hae* Fragments derived from B10a† and C1a*	Molecular weight (daltons × 10^{-6})
			A4	Φ80h	14.0	Z1†*	1.75
			A6	Φ80h	11.0	Z2†	1.12
			E4	Φ80h	1.50	Z3†*	1.05
			B10a†	Doublet	5.6†	Z4†*	0.77
			D1a	Doublet	2.9	Z5†	0.54
A7a	doublet	10.5	F3a	Doublet	0.93	Z6†*	0.33
			F3b	Doublet	0.93	Z7†*	0.22
			A4a	Doublet	13.7		
			A6a	Doublet	11.3		
			C1a*	Singlet	4.1*	Sum B10a† fragments	5.78†
			D1a	Singlet	2.9		
B1a	singlet	8.3	F3a	Singlet	0.93		
			F3b	Singlet	0.93		
			A4a	Singlet	13.7		
			A6a	Singlet	11.3	Sum C1a* fragments	4.12*

Fragment molecular weights were determined by electron microscopy and/or comparison of relative electrophoretic mobility with SV40 *Hin*d DNA fragments of known molecular weight as described elsewhere[23]. The horizontal arrows indicate which *Hin*d fragments were derived from the *Hin*cII fragments A7a and B1a.

*, †, Derivation of individual *Hae* fragments from the parental *Hin*d fragments B10a and C1a.

weights of the *Hae* fragments add up to the molecular weights of the fragments from which they were derived. The most interesting feature of the *Hae* digestion profiles is the existence of two doublet-unique fragments, Z2 and Z5. Their presence is evidence that there is some number of base pairs—a minimum of four for the restriction site (K. Murray, personal communication), which occur as an unduplicated sequence between the two sequences containing the $tRNA_I^{Tyr}$ genes (Fig. 6).

$tRNA_I^{Tyr}$ gene fragments

These results indicate the potential usefulness and feasibility of successive digestion-fractionation cycles using different nucleases with appropriate site-specificities. The DNA fragments in Fig. 5 are the final product of three such cycles using the nucleases *Hin*cII, *Hin*dIII, and *Hae*.

A model showing how the relevant fragments produced in each of the three digestions might be related to one another in the intact genome is shown in Fig. 6. As shown above, the maximum size for one $tRNA_I^{Tyr}$ gene (including the intergenic sequence) is 200–260 base pairs. Taking the minimum size of four base pairs for the unduplicated intergenic sequence gives a maximum size of 256 base pairs for the $tRNA_I^{Tyr}$ gene. Taking the minimum size for the $tRNA_I^{Tyr}$ gene (135–140 base pairs) gives a maximum size of 125 base pairs for the intergenic sequence between the duplicated genes.

Each of the three endonucleases used in this work produces a different size $tRNA_I^{Tyr}$ gene fragment. The *Hin*d fragments B10a and C1a, which are two to three times the estimated size of the $tRNA_I^{Tyr}$ gene(s) (plus intergenic sequence), are the most favourable size for studying *in vitro* the regulation and maturation aspects of tRNA synthesis and also the overall structure of the $tRNA_I^{Tyr}$ genes. In both of these areas, the larger *Hin*cII fragments A7a and B1a may also prove useful. The seven *Hae* fragments, which are in the subgenic size range, are the most favourable for nucleotide sequence analysis.

The ability to isolate pure preparations of these fragments in chemical quantities should make a complete analysis of the $tRNA_I^{Tyr}$ gene(s) a feasible prospect. Similar experiments are being carried out with the gene coding for $tRNA_{II}^{Tyr}$, the major species, on the premise that this comparison may help to identify those features of gene structure which are important in the regulation of tRNA synthesis.

We thank Nancy Brimlow and David Freifelder for electron micrographs of the DNA fragments. This work was supported by grants from the National Institutes of Health and the American Cancer Society.

Radio spectra of OH471 and OQ172

RADIO spectra for the highly redshifted $z \geq 3.40$ quasars OH471 (ref. 1) and OQ172 (ref. 2) are presented here for frequencies between 16.7 MHz and 85.3 GHz. The spectra are complex. Both have a peak at or near 1.4 GHz and a second peak near or above 85 GHz. Both have a low frequency cutoff, the one for OH471 being especially sharp. OH471 sometimes seems to be variable at 31 GHz on a time scale of days but the source appears to be stable at 10.7 and 22 GHz.

Although flux densities for these sources had already been published at a few frequencies, the unusual nature of the objects encouraged us to undertake further measurements at as many frequencies and epochs as possible in order to obtain much more complete data in both frequency and time domains.

All observations, new and previously published, are listed in Table 1. The spectra of the sources are shown in Fig. 1. Figure 2 is a plot of flux density against time for OH471, which has shown some evidence of variability. The observations involve more than 120 measurements at many epochs from 1963 to March 1974 at 25 different frequencies between 16.7 MHz and 85 GHz.

Flux densities have been adjusted to the Wills scale[3]. The flux density on this scale was obtained by multiplying values on the KPW scale[4] by 1.23 at 178 MHz, 1.10 at 750 MHz and 1.06 at 1.4 GHz. No adjustment was made at frequencies of 2.65 GHz and above since the difference between the Wills scale, the KPW and other commonly used scales is small (less than 5%).

Measurement details of the new observations are as follows:

Algonquin. Measurements with the 46-m Algonquin telescope were made on OH471 and OQ172 at 10.7 GHz between April and December 1973, and at 22.2 GHz during February 1974. The ARO 10.7-GHz receiver has a noise temperature of 120 K and a bandwidth of 100 MHz. The 22.2-GHz receiver has a noise temperature of 200 K and a bandwidth of 500 MHz. The observations were made by Andrew, Gearhart, Purton, Feldman and Marsh.

Bonn. Measurements were made with the 100-m telescope in July 1973 at 10.7 GHz and in August 1973 at 1.42 GHz with the results given in Table 1. Observers included Thiel, Fürst and Hirth.

Cambridge. The flux densities of both OH471 and OQ172 are below the 4C limit of 2.0 Jy at 178 MHz but an examination of the interferometer records yielded the values given in Table 1. In addition flux density measurements at 5.0 GHz of OH471 were made in June and July 1973 and of OQ172 in August 1973 and March 1974 with the 5-km telescope (Table 1) and accurate positions determined (Table 2).

Grakovo. Flux density measurements on OH471 and OQ172 were made during 1973 at decameteric wavelengths with the (Ukrainian) UTR-2 radio telescope. This telescope consists of two arrays of wideband horizontal dipoles arranged in the form of a 'T'. One array, oriented north-south, is 1,860 m long and has 1,440 dipoles. The other, or east-west, array is 900 m long and has 600 dipoles. The array operates over the frequency range 10 to 25 MHz in a five-beam mode.

Observations on OH471 and OQ172 with the UTR-2 telescope showed no detectable signal from which it may be concluded that the flux density of both sources is less than 10 Jy (f.u.) at 16.7 MHz and less than 5 Jy at 25 MHz. These observations support the conclusion that neither source has a low frequency component. The minimum detectable flux density is necessarily large because of confusion effects combined with the high sky background temperature ($\sim 10^5$ K).

Green Bank. Observations were made at 1.4 and 2.695 GHz with the 300-ft meridian transit telescope, using multiple-feed systems to determine accurate declination pointing corrections. The procedure has been described by Bridle *et al.*[5]. At 1.4 GHz, OQ172 was observed in February 1970 and OH471 in May 1973. At 2.695 GHz, OQ172 was observed in January 1973 and both QSOs were observed in April, May, and June 1973. Observations with the three-element interferometer were made in February 1974 at 2.695 and 8.085 GHz. The 300-ft telescope measurements were made by Bridle and the three-element interferometer measurements by Warner, Assousa, and Balick.

Kitt Peak. Observations at 31.4 and 85.3 GHz were made with the 11-m telescope at Kitt Peak during six days in March 1973 on OH471 and on four days in July 1973 on both OH471 and OQ172. Techniques were similar to those described by Conklin *et al.*[6].

Itapetinga. Observations were made during July and August 1973 and again in February 1974 with the Mackenzie University (Brazil) 13.7-m radome-enclosed telescope at 22.2 GHz. The receiver bandwidth is 100 MHz and the system temperature about 2,500 K. A double beam feed was used consisting of two horizontally polarised horns with beam separated in the sky by 9′. The data were corrected for atmospheric absorption and radome attenuation.

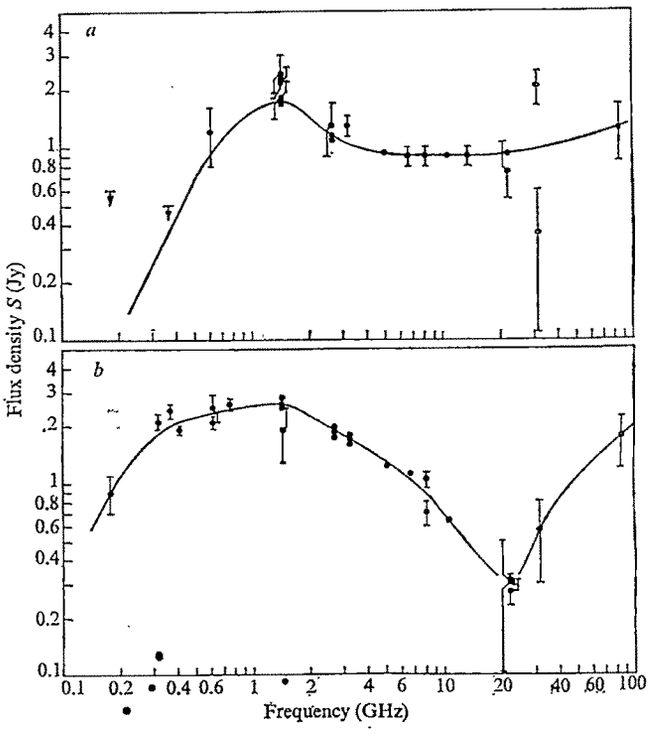

Fig. 1 Flux density (S) of OH471 (a) and OQ172 (b) against frequency. The points with no error bars have errors within the extent of the solid circle.

Measurements were made on seven days between July 25 and August 3, 1973, and on seven days in February 1974, for OH471 and on four days between July 25 and 29, 1973, for OQ172. Each measurement averaged more than 2 h of observing time. The measurements on OH471 were difficult because of the low elevation angle of the source (less than 21°).

Ohio. Records stored in the Ohio State University (OSU) Radio Observatory archives for epochs as early as 1963 were used to obtain flux densities for OH471; records back to 1966 were examined for data on OQ172. The observations were made with the OSU radio telescope with techniques as given by Fitch *et al.*[7]. Further observations of OH471 were made at 1.42 GHz with the OSU radio telescope in January 1974.

Stanford. The aperture synthesis interferometer was used during July 1973 for measurements at 10.7 GHz. Both sources were unresolved indicating that their angular diameters must be less than 10″.

Texas. The Broadband Synthesis Interferometer (BSI) was used to search for OH471 at 365 MHz on two occasions during May 1973 and on five occasions during January 1974. It was not found, but assuming that the source is constant at 365 MHz the upper limit is 0.5 Jy with 95% confidence. Techniques are similar to those described by Ghigo and Owen[8].

d, relative to 3C298=5.95 Jy; e, relative to 3C298=1.03 Jy. Otherwise as Table 1*a*.

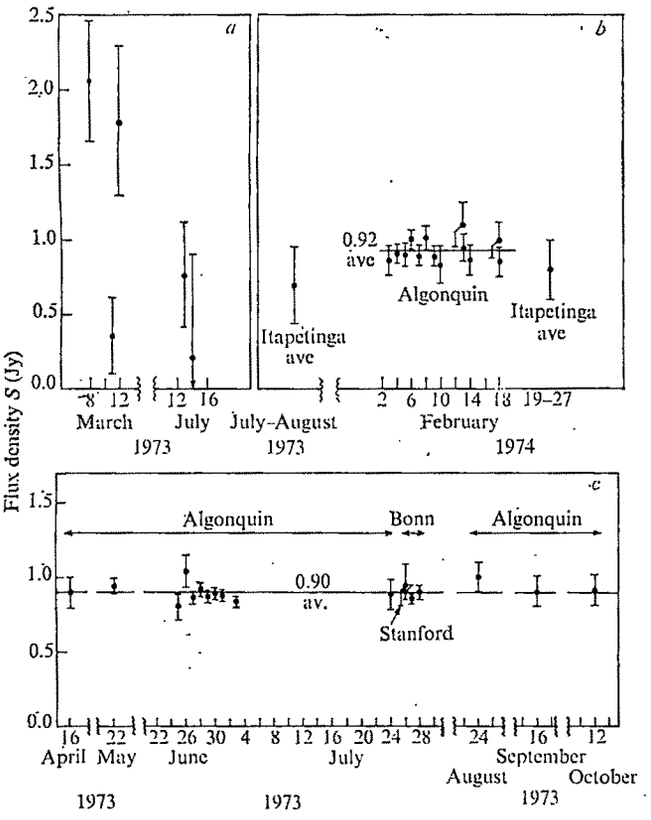

Fig. 2 Flux density of OH471 as a function of date for frequencies: 31.4 GHz(*a*), 22.2 GHz(*b*), and 10.7 GHz(*c*). *a*, All Kitt Peak data; *b* and *c* as labelled.

The spectra of OH471 and OQ172, shown in Fig. 1, are complex. Both have a low-frequency cutoff. The cutoff is particularly sharp for OH471. Both have a peak near 1.4 GHz and (if OH471 is not varying at 31.4 GHz) both have a second peak near or above 85 GHz suggesting at least two components.

The measurements on OH471 at 31.4 GHz made at Kitt Peak are suggestive of variability. But the observations at 22.2 GHz made at Algonquin show no evidence of variability and the observations at Itapetinga at the same frequency are inconclusive (Fig. 2). No observations were reported from other observatories for dates on which variability was observed at Kitt Peak so there is no direct disagreement. But the stability and greater precision of the Algonquin results are statistically inconsistent with the variability suggested by the Kitt Peak results if OH471 is a frequently fluctuating erratic variable as the later results imply. A frequency of 22.2 GHz is close enough to 31.4 GHz that a noticeable change might be expected to occur at 22.2 GHz accompanying a large variation at 31.4 GHz.

Measurements of OH471 between April and December 1973 made at Algonquin, Bonn and Stanford are all consistent with a constant flux density at 10.7 GHz.

Records from OSU of OH471 at 1.415 GHz since 1963 (Table 1) show no significant change in flux density until 1970. But between 1970 and 1974 there is a marginally significant decrease. So there may be slight variability at 1.4 GHz on a time scale of years.

Table 2 Radio positions of OH471 and OQ172

Source	α(1950.0)	δ(1950.0)	Observatory
OH471	$06^h42^m53.^s023(0.^s005)$	$+44°54'30''.89(0''.05)$	Cambridge (5-km teleslope)
OQ172	$14^h42^m50.^s479(0.010)$	$+10°11'12''.35(0''.15)$	Cambridge (5-km telescope)

According to Andrew *et al.*[9] there is a 90% or greater probability of sources with centimetre-excess spectra, like OH471 and OQ172, exhibiting radio variability. Variability is suggested in OH471 and it will be interesting to continue measurements of OQ172, particularly in the region 10 to 40 GHz, to find if any variability exists.

The spectrum of OQ172 (Fig. 1*b*) is complex. It would take four or five straight (power law) segments to give even a first order fit. The spectrum of OH471 is similarly complex and is further complicated by apparent variability at 31 GHz.

The Algonquin Radio Observatory is operated by the National Research Council of Canada as a national radio astronomy facility. The Green Bank and Kitt Peak facilities of the National Radio Astronomy Observatory are operated by Associated Universities, Inc., under contract to the National Science Foundation. The Stanford University Radio Astronomy Institute is supported by the National Science Foundation.

New position of Cen X-3 from Copernicus

THE X-ray source Cen X-3 (3U1118-60) is part of a pulsating, eclipsing, binary system[1,2]. The third Uhuru catalogue[3] gives a best position for the source of α (1950) = 11 h 18 min 55 s, δ (1950) = −60° 19′ 5″ with a 90% confidence error box of area 7 × 10^{-4} deg². At present this X-ray source has not been positively identified with an optical counterpart although several candidates have been suggested— (refs 4–6 and L. Webster, unpublished).

The Mullard Space Science Laboratory experiment on the Copernicus satellite has been used to observe Cen X-3 primarily with a view to refining the position but also to observe eclipse transitions at energies lower than those observed by Uhuru. The instrumentation which has been described elsewhere[7]; contains three co-aligned X-ray detection systems. The first contains a grazing incidence telescope (nonfocusing flux collector) and proportional counter sensitive in the nominal energy range 1.4 to 4.2 keV with circular apertures defining fields of view of 10 arc min (large), 3 arc min (intermediate) and 1 arc min (small); the second is similar and is sensitive in the energy range 0.7 to 2.0 keV with apertures defining fields of view of 10 arc min (large), 6 arc min (intermediate) and 2 arc min (small); the third is a collimated proportional counter sensitive in the energy range 4 to 12 keV with a fixed aperture of 3°.

Cen X-3 was observed by Copernicus between 1900 UT on February 17 and 0200 UT on February 18, 1973. From 1900 UT to 2130 UT on 17 February the package was pointed at α (1950) = 11 h 19 min 1.2 s, δ (1950) = −60° 18′ 41″ using the large apertures on the two telescopes and the X-ray source was observed emerging from an eclipse. The data from the three detectors are shown in Fig. 1; the background has been subtracted in the manner described previously[7]. The effectiveness of this method of background subtraction is well illustrated between 0000 UT and 0200 UT on February 18 when the satellite was passing through the edges of the radiation belts and there are no signs of their effects on the 4 to 12 keV signal.

Figure 1 also shows that the lower energy X rays appear later. This effect was predicted by Schreier *et al.*[2] since they assumed the length of the transition was not due to an extended source but to an extended atmosphere around the occulting star. The present observations confirm this prediction of an extended atmosphere, clearly showing the 1.4 to 4.2 keV signal appearing more than an hour after the 4 to 12 keV signal. There is very little emission at 0.7 to 2.0 keV which reinforces the interpretation of an absorbing atmosphere being present.

Between 2130 UT on February 17 and 0200 UT on February 18 the 2U error box was observed using the intermediate apertures on the two telescopes. Seven points in the error box were chosen for observation with times of typically 20 integration periods (one integration period being 62.5 s). The points were separated by 2 arc min so there was considerable overlap using the intermediate fields of view and significant emission was observed in three of these overlapping fields of view. Simultaneously the high energy system monitored the source and Fig. 1 shows that during this time the intensity of the source varied by less than 10% in the energy range 4 to 12 keV. (The response across the 3° field of view of the high energy detector is approximately triangular and the correction due to the small pointing excursions is less than 2%). So we assume there were no significant variations in the intensity of the source on time scales of minutes during these observations. Since the efficiency profiile of the telescope field of view is well known, an estimate of the most likely position for the source can be made using the ratios of the count rates in the overlapping fields of view for the 1.4 to 4.2 keV system. This best position is at α(1950) = 11 h 19 min 1.8 s and δ(1950) = −60° 20′ 27″.

The error box for this position contains two components. First, there is a component due to the counting statistics giving a rectangular box 40 × 50 arc s and, second, one due to pointing uncertainties, of 10 × 20 arc s. The latter is derived from repeated observations of Sco X-1 which has a position known to better than 1 arc s. Combining these two sources of error gives a 90% confidence error box with corners shown in Table 1.

Table 1 Corners of error box for Cen X-3

	h	min	s		°	′	″
α (1950) =	11	19	1.1	δ (1950) =	−60	19	49
	11	19	7.1		−60	20	11
	11	19	3.7		−60	21	5
	11	18	57.7		−60	20	43

These positions are shown schematically in Fig. 2 with the 90% error box from the 3U catalogue[3]. These error boxes marginally overlap, the Copernicus error box being much smaller (2.4 × 10^{-4} deg²) and more to the south-east.

Several optical candidates have been suggested for Cen X-3 and it is worthwhile examining these in the light of this new X-ray position. Margon and Wray[4] have suggested WRA795, α(1950) = 11 h 18 min 56 s, δ(1950) = −60° 15′ 48″, but this can be definitely eliminated as being over 5 arc min north of this new position. The m_V = 15 blue star suggested by Liller[5], L in Fig. 2, has been questioned by van Genderen[8] who found that the optical period of the star did not fit the X-ray period. This star lies well outside the Copernicus error box and hence can

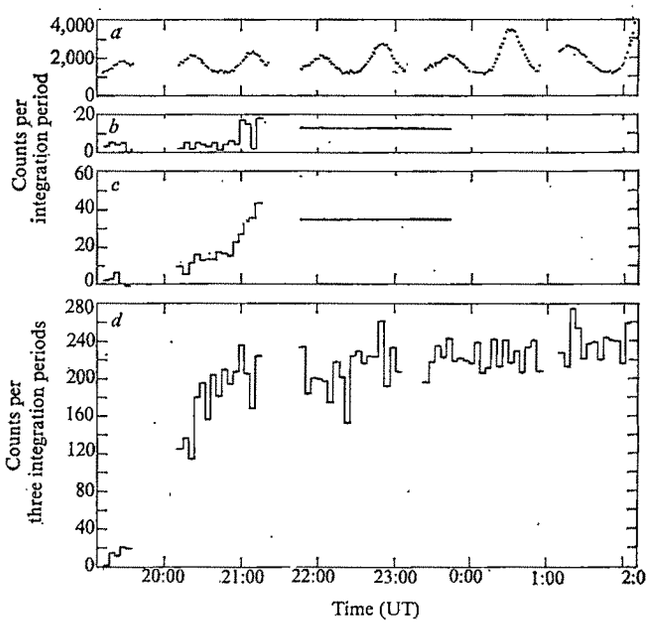

Fig. 1 Copernicus observations of Cen X-3 between 1900 UT on 17 February and 0200 UT on 18 February, 1973. Note the de-eclipse of the X-ray source between 1930 UT and 2100UT. Integration period = 62.5 s, dead time between integration periods = 23 s. *a*, Charged particle background; *b*, 0.7 to 2.0 keV X rays; *c*, 1.4 to 4.2 keV X rays; *d*, 4 to 12 keV X rays.

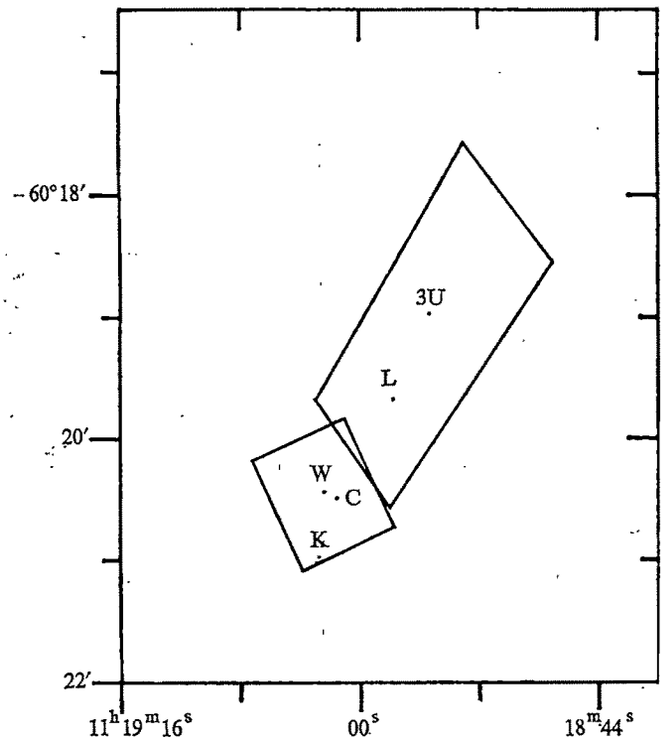

Fig. 2 X-ray error boxes for Cen X-3. C, Copernicus best position; 3U, Uhuru best position[3]; L, W, K, see text. K is the suggested position for Cen X-3.

be eliminated. Webster (unpublished) has suggested CPD −59° 3380 (star 14 in Fig. 1 of ref .9) marked W in Fig. 2. This star is an early B giant, and so may have insufficient mass to be the primary of the system. Krzeminski[6] has found optical intensity variations, which seem to have a period equal to the X-ray period, in the $m_V \approx 13$ red star (K in Fig. 2). This star has been classified as an 09.5—BO.5 Ib star [10,11] and so has sufficient mass to agree with the calculation of Schreier *et al*[2].

Both of these last two stars are inside the Copernicus error box. However, the evidence presently available indicates that the star suggested by Krzeminski at α(1950) = 11 h 19 min 03 s, δ(1950) = −60° 21′ 00″, is the optical counterpart for the primary of the Cen X-3 system.

We thank F. J. Hawkins and the UCL-MSSL Copernicus team for assistance, Professor R. L. F. Boyd for encouragement and W. Forman, C. Jones, B. Margon, P. Murdin, S. Rappaport, E. Schreier and L. Webster for discussions. K.O.M. acknowledges support from the Science Research Council.

Interpretation of double structure in the celestial γ-ray bursts

THE essentially isotropic distribution of the Vela satellite γ-ray bursts[1] implies that the sources are either very local and galactic, or very remote and extragalactic. Of the theories for a remote origin there are two schools of thought, either that these γ-rays originate in shock waves during the formation of type II supernovae[2] or that they represent transient pulses of blackbody emission associated with the collapse of a white dwarf to a neutron star[3].

A problem common to both of these theories is that they do not readily account for the fact that most of the observed bursts are double, and that the second pulse is frequently comparable in magnitude to the first.

I here make the suggestion that perhaps the sources of these γ-ray bursts may be identified with the collapse of a rotating magnetised star, following a model of the type computed by LeBlanc and Wilson[4]. In this model, at the later stages in the collapse, axial jets are formed in ~2.5 s which, in their specific example, carry energies $\sim 10^{51}$ erg at a temperature of $\sim 3.5 \times 10^9$ K, comparable to those estimated and required in ref. 3. The main objective of this suggestion is that if acceptable theoretically it could readily account for the double pulses.

Figure 1 represents a replot in polar coordinates of the density profile of Fig. A2a in ref. 4 at $t = 2.67$ s and $\rho = 3 \times 10^6$ g cm^{-3}. Let θ be the angle of tilt between the rotation axis of the source and a perpendicular to the source-Earth line and let φ be the corresponding azimuth angle, φ being zero in Fig. 1.

If now the observed γ-ray bursts originate from such collapsing objects whose axes are randomly distributed, the following predictions are made:

(1) The pulses will in general be double, for radiation will be observable from both polar jets. (2) The delay time T between the two pulses will in general increase with τ, the duration of the individual pulses. (3) Single pulses will arise for all

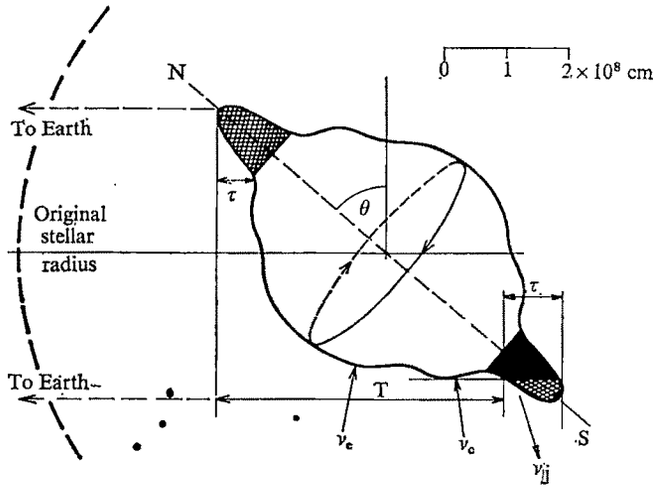

Fig. 1 Diagram to illustrate the active polar regions on a collapsing rotating star with an axial magnetic field, from LeBlanc and Wilson[4].

values of φ when $\theta=0$, for all values of θ when $\varphi=\pi/2$, and if one or other of the jets is totally obscured by the equatorial regions of the collapsing star. (4) The first pulse will always be the stronger—because a larger fraction of the nearer jet is visible to the observer than the farther jet and because Doppler shifts of radiation from matter moving along the jets, resolved along the line of sight, will increase both the flux and the photon energy of the radiation from the nearer jet; and if some or all of the radiation is nonthermal, one might expect it to be directed predominantly along the jet. (5) There should never be more than two pulses.

The duration of the pulses τ will be compounded of the growth time and axial development of the jets, the rate of radiation production and the time difference corresponding to the line of sight path difference between the tip and the base of the 'visible' portion of the jet.

I now look at these predictions in the light of the data. Of the latest list[5] of Vela events I find, in support of prediction (1) above, that of the 19 events for which information on the character of the pulses is presented, 12 are double. Figure 2 shows a plot, for these double events, of the duration τ of the first pulse with respect to the separation T between the pulses (presumed to be measured from the onset of the pulses). The event numbers on the plot correspond to those used in ref. 5. It is at once apparent that τ increases steadily with T, in agreement with prediction (2). I find seven pulses which are single, consistent with (3), five being wide (≥ 1 s) and two narrow (<1 s). The wide pulses may correspond to overlapping of bursts from the individual jets or to relatively slow axial development of the jets. In support of prediction (4) I note that for the double pulses the first component is the larger in all cases, with the possible exception of event 71-2, for which the description is ambiguous. Regarding the multiplicity, prediction (5), the only event which reveals more than two pulses is 72-4, with a third event at $T=28$ s.

Regarding the intensity of the thermal radiation from the poles in the LeBlanc–Wilson model, the quoted mass and temperature of the jets, $\sim 10^{32}$ g and $\sim 3\times 10^{9}$ K respectively, are sufficiently close to the corresponding values in ref. 3 that the γ-ray yields, and hence the distance-range of the sources ($\sim$25 to 300 Mpc) will be comparable on the two models.

A crucial question is whether the jets can penetrate the residual stellar envelope, to densities at which the medium is optically thin to $\sim$100 keV γ rays, and in this connection it would be of interest to know: (a) how the strength, temperature and axial development of the jets in this model change by varying the input parameters; (b) the subsequent history of the jets beyond $t=2.67$ s, at which their calculations were halted; and (c) what effects the axial magnetic field may have on the cooling time. The absolute time scales present a problem. On the specific model in ref. 4, the tips of the jets are $\sim 7\times 10^{8}$ cm apart at $t=2.67$ s, so that for $\theta=60°$, $T\sim 0.02$ s, a pulse spacing less than that measured for the shortest double event, Los Alamos burst No. 69–1. To obtain pulse separations of several seconds, reported in ref. 5, as well as by others[6], we require that the post-collapse dimensions be far larger. We therefore ask whether Colgate's larger Type II $30M_{\odot}$ stars[2], with initial radii 10^{12} to 10^{14} cm can on collapse also develop axial jets, which could then radiate thermally at the required temperatures.

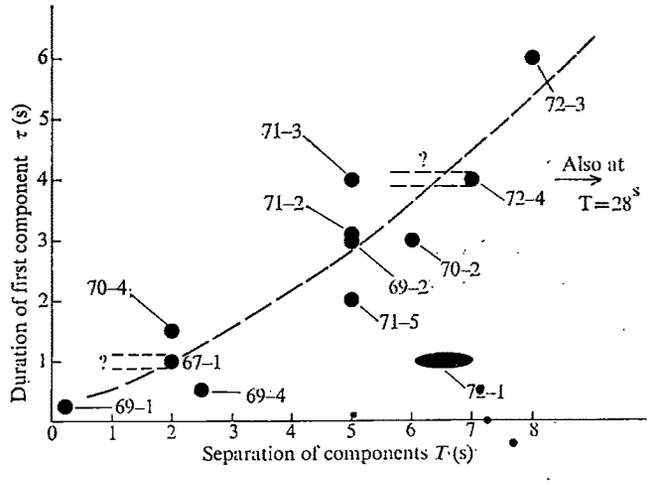

Fig. 2 A plot of the duration τ of the first component of all double pulses listed in ref. 5, with respect to the separation T between the two components.

Finally some remarks on the fine structure. There seems to be no difficulty in explaining quite large intensity fluctuations within the framework of these ideas. There will be temperature fluctuations in the jets and fluctuations in the opacity of the outer regions of the envelope; these fluctuations will appear rapid to the observer, since the velocity vectors v_j and v_e of the jet and envelope respectively (Fig. 1) have opposite sign, see also Figs A6 in ref. 4.

It had previously been suggested[3] that the secondary pulses and the fine structure could be interpreted as due to the rebound of the neutron star and/or its subsequent oscillations. This, however, would seem rather unlikely, as one would expect the primary catastrophic implosion, in view of its vast energy release, to outweigh by far the secondary effects, so that the γ rays from the latter would be expected to be relatively much less intense, by perhaps some orders of magnitude, and hence below the threshold of the existing detectors.

A more thorough check on these ideas will be possible when the structure curves of the individual bursts are available.

While the LeBlanc–Wilson model on which these ideas are based may be rather too specialised, it seems likely that any kind of outward-propagating shock wave in a star which is significantly rotationally flattened, would give rise to two hot spots on the surface and therefore a double burst.

I thank Professor M. J. Rees for comments.

Fifteenth-order harmonics in the geopotential

THE Earth's gravitational potential is usually expressed as a double infinite series of spherical harmonics. Analysis of thousands of photographic and laser observations of satellites, together with gravity measurements has yielded global models of the geoid[1-3] accurate to about 3 m on average. The harmonic coefficients have been evaluated complete up to degree and order 16 in the Goddard Earth Models (GEM) 4 and 6 (refs 1 and 2), and up to degree and order 18 in the Smithsonian Standard Earth III(SSE)[3]. Models currently being evaluated will extend to degree 25 (D. E. Smith, personal communication). Although these comprehensive global solutions give the overall geoid shape or gravitational field quite accurately, the individual harmonic coefficients of order between 10 and 20 are poorly determined among the matrix of 300 or more coefficients, and accurate methods for evaluating coefficients of a particular order are badly needed.

One of the best methods is to analyse the changes in the orbital elements of Earth satellites which pass slowly through a resonance with the Earth's gravitational field, when the ground track repeats after an integral number of revolutions. The 15th-order resonance, when the successive equator crossings are 24° apart and the track is repeated after 15 revolutions, is particularly useful because 15th-order resonant satellites circulate at heights near 500 km, where air drag is strong enough to ensure that the orbit contracts substantially in the course of a year. Consequently, each year many satellites experience 15th-order resonance as their orbits contract, and some of them pass through the resonance quite slowly, so that the orbital perturbations which result from 15th-order harmonics will build up[4,5]. These perturbations can be analysed to determine 15th-order coefficients in the geopotential.

The longitude-dependent part of the Earth's gravitational potential at an exterior point (r, θ, λ) may be written in normalised form[6] as

$$(\mu/r) \sum_{l=2}^{\infty} \sum_{m=1}^{l} (R/r)^l P_l^m (\cos\theta) \cdot [\bar{C}_{lm} \cos m\lambda + \bar{S}_{lm} \sin m\lambda] N_{lm}$$

where r is distance from the Earth's centre, θ is colatitude, λ is longitude (positive to the east), μ is the gravitational constant for the Earth (398,601 km^3 s^{-2}), R is the Earth's equatorial radius (6,378.1 km), $P_l^m(\cos\theta)$ is the associated Legendre function of order m and degree l, and $\bar{C}_{lm}$ and $\bar{S}_{lm}$ are the normalised tesseral harmonic coefficients which is to be evaluated (for $m = 15$). The normalising factor N_{lm} is given by[6]

$$N_{lm}^2 = 2(2l + 1)\,(l - m)!/(l + m)!$$

For nearly circular orbits passing through 15th-order resonance, the rate of change of orbital inclination, i, is proportional to[5] $(\bar{C}_{15} \sin\Phi - \bar{S}_{15} \cos\Phi)$, where $\bar{C}_{15}$ and $\bar{S}_{15}$ are 'lumped' 15th-order coefficients[7] and Φ is the 'resonance angle' (written as Φ_{15} in ref. 7), which becomes stationary at resonance. A computer program, THROE, has been developed[7] to fit the observed variation of i with a theoretical curve which includes not only the terms in sin Φ and cos Φ, but also terms in sin 2Φ, sin 3Φ, and so on, and terms involving the eccentricity, e, if these are appreciable.

The values $\bar{C}_{15}$ and $\bar{S}_{15}$ found from a particular orbit can be expressed as a linear sum of individual coefficients $\bar{C}_{l,15}$ and $\bar{S}_{l,15}$ of odd degree ($l = 15, 17, 19 \ldots$). To determine these individual coefficients, values of C_{15} and S_{15} need to be found for orbits at a wide variety of inclinations. The first pair of values, determined by Gooding[7] were from analysis of Ariel 3 (1967-42A) at inclination 80°. In 1972 King-Hele utilised the orbits of three further resonant satellites[8] at inclinations of 51°, 62° and 74°, to evaluate the coefficients of order 15 and degree 15, 17, 19 and 21. We have now been able to analyse the orbits of another eight resonant satellites, at inclinations of 31°, 33°, 38°, 51°, 54°, 56°, 74° and 90°. From these and the previous orbits we have obtained values[9] for the 15th-order coefficients of degree 15, 17, 19 . . . 31.

Figure 1 shows the fitting for one of the 11 satellites, Cosmos 395 rocket (1971-13B), which is in a circular orbit at 74° inclination: this satellite is fairly typical, both in the accuracy of the fitting and in the magnitude of the effect. The main resonance oscillation has an amplitude of about 0.015° and the theoretical curve fits well[10], giving values of $\bar{C}_{15}$ and $\bar{S}_{15}$ accurate to 4%.

From the 11 satellites we have derived 11 pairs of linear equations between the coefficients $\bar{C}_{l,15}$ and $\bar{S}_{l,15}$ ($l = 15, 17, 19 \ldots$). To these equations we added a pair derived by Wagner and Klosko[11], and nine pairs of equations specifying constraints on the values of the coefficients given by Kaula's rule-of-thumb[6] that the coefficient of degree l is likely to be of order $10^{-5}\, l^{-2}$. These 21 pairs of equations were then solved by least-squares, taking account of the correlations between $\bar{C}_{15}$ and $\bar{S}_{15}$, to determine nine pairs of values of the individual

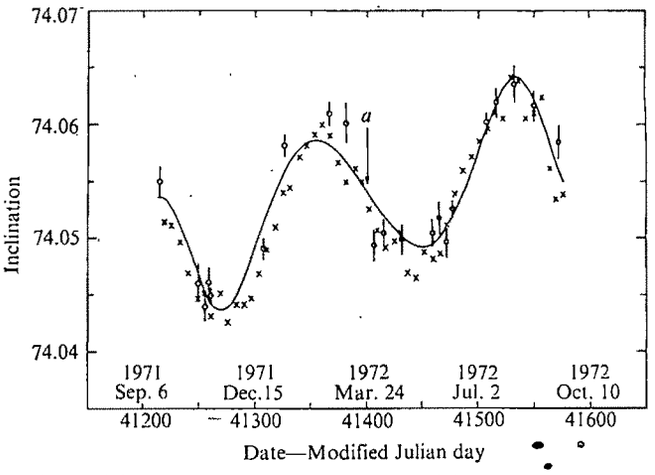

Fig. 1 Values of inclination at resonance of Cosmos 395 rocket (1971-13B), with fitted theoretical curve (—). Crosses, values from United States Navy orbits (s.d. taken as 0.003°); ○, values determined at the Royal Aircraft Establishment from Hewitt camera, visual and United States Navy observations (s.d. shown as error bars); *a*, 15th-order resonance on March 24, 1972.

coefficients of 15th-order, from degree 15 up to degree 31 (Table 1).

Table 1 shows that the numerical values of the C coefficients, of which seven out of nine exceed 10^{-8}, are much larger than the S coefficients, of which only one exceeds 10^{-8}. In a sense this bias is a result of chance, because the choice of reference longitude for defining C and S (the Greenwich meridian) is arbitrary. The effect may, however, be geophysically significant, if the 15th-order S coefficients are small for all degrees.

Table 1 Values of $\bar{C}_{l,15}$ and $\bar{S}_{l,15}$

l	$10^9\bar{C}_{l,15}$	$10^9\bar{S}_{l,15}$
15	−21.5±0.9	−8.4±0.9
17	4.4±1.6	9.0±1.5
19	−15.6±2.6	−14.1±2.7
21	10.4±3.0	7.3±3.5
23	22.5±2.8	1.2±4.4
25	−0.9±4.7	−3.8±5.3
27	−11.2±3.3	9.1±3.2
29	−20.5±5.4	−1.2±6.1
31	17.7±6.6	−1.0±7.1

The last two S values (Table 1) are not significant, and their omission would reduce the standard deviation (s.d.) for the other values. They have to be included because of their correlations with the C values, but it is probable that the real errors in the S coefficients up to degree 27 are smaller than the given s.d.

Another feature of interest (Table 1) is that the C values, though larger than the S values, are still mostly less than the values indicated by the rule-of-thumb $10^{-5}\, l^{-2}$. Thus, the constraint equations used turn out to be quite weak, and the values of the individual coefficients are determined primarily by the 11 pairs of equations from the orbital analysis.

Finally, the rather large values of $\bar{C}_{29,15}$ and $\bar{C}_{31,15}$ indicate that the evaluation ought to be carried to a higher degree. We hope to do this after observation of further satellites passing through 15th-order resonance and analysis of their orbits. There is a particular need for results at orbital inclinations between 40° and 50°, and between 64° and 73°.

High resolution α spectrometry

DEFICIENCIES in energy resolution have been an obstacle to the widespread application of dielectric track detectors[1]. The best resolution so far obtained covered a span of only 150 to 200 keV (ref. 2). Now a procedure has been developed which uses the range differences obtained with α particles of diverse emission energies. This procedure provides a substantially improved energy resolution.

The pits, which are etched on to the front of dielectric track detectors, are a result of primary ionisation, and the diameter of each pit therefore provides a measure of energy. Unfortunately, however, the properties of the material used and the etching conditions also influence the diameter of the pits. At the onset of etching, particles have an entrance energy that is higher than the threshold energy. The onset is not very well defined because, near the threshold, the rate of track etching, V_t, differs only slightly from the rate of volume etching, V_b, of the intact material. This explains the low growth of etch pits in the initial phase. If, however, detector sheets are etched from the rear the onset of etching is sharply defined because, as the particle trajectory is approached, the density of radiation damage

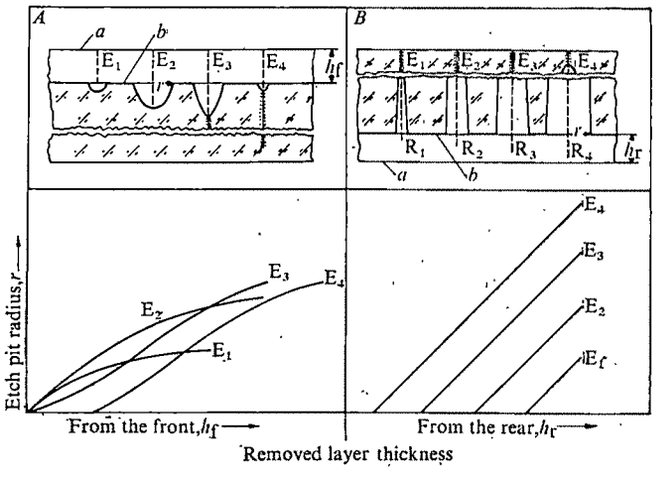

Fig. 1 Two methods of energy determination. The track evolution is shown as a function of the thickness of the removed surface: *A*, etching the frontside of a medium sensitive detector such as cellulose acetate leads to a dependence of the etch pit growth from the particle energy used for energy determination; *B*, etching the rear of a very sensitive detector perpendicularly irradiated with α particles of different energies results in a pit radius kinetic with a slope which is independent of the particle energy, in which the differences of the etch pit radii are equivalent to the range differences of the α particles. *a*, original surface; *b*, etched surface.

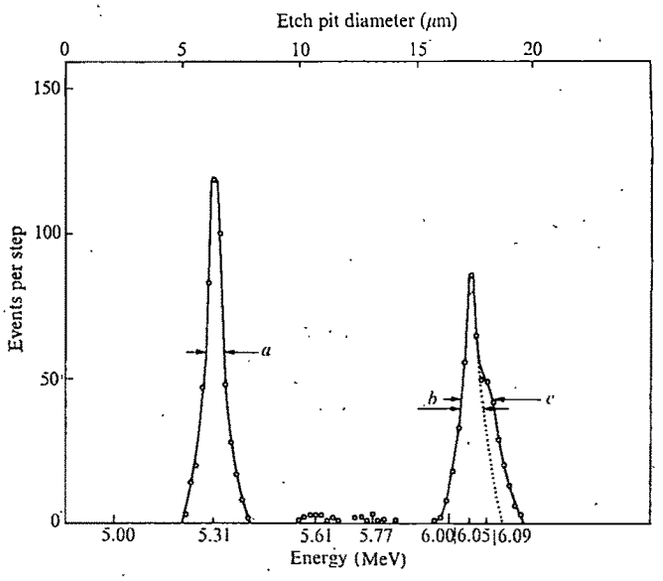

Fig. 2 Distribution of the etch pit diameters measured on the rear of a highly sensitive cellulose nitrate detector irradiated with α particles of ^{210}Po (5.31 MeV) and of ThC (5.61, 5.77, 6.05 and 6.09 MeV). *a*, 54 keV; *b*, 46 keV; *c*, 71 keV.

reaches a maximum. The radius of the etch pit produced then increases proportionally to the thickness of the surface removed from the rear (Fig. 1).

A necessary precondition of this method is that the α particles come to rest in the detector sheet. For maximum resolution, the particles must enter the detector normal to its surface, a condition which can be easily realised. If irradiation occurs under 2π geometry, only round etch pits with an accurate concentric configuration are evaluated. To obtain maximum energy resolution I have used very sensitive cellulose nitrate sheets[3]. In this detector even α particles create a very high track etch rate, so that immediately after the formation of an etch pit, the radius, r, will increase at the same rate as the volume etch rate. Up to a diameter of 25 μm no deviation from this relationship has been observed. Thus, we obtain the optimum condition $\Delta r = \Delta R$ that is, the difference in diameter of the etched tracks corresponds with twice the range difference, ΔR, of the α particles. With one-sided etching of the rear of the detector the particle range corresponds to the sum of the residual thickness and the etch pit radius. If the range – energy characteristic of the particles in the detector material is known, the energy of the particles can be determined.

To demonstrate the high degree of energy resolution of the new method a detector sheet of 38 μm was irradiated with α particles from a ^{210}Po source (5.31 MeV) and a ThC source (5.61 MeV), (1.1%), 5.77 MeV (1.8%), 6.05 MeV (68%) and 6.09 MeV (27%) at a pressure of 5×10^{-2} torr, with a distance of 50 mm between source and detector. The irradiated surface had a diameter of 1.5 mm. The rear of the sheet was then etched, using 30% KOH at 60° C until the thickness was reduced to 25.7 μm. All the emission energies from 5.31 to 6.09 MeV were thus obtained.

The determination of energy was based on the microscopic measurements, at each peak, of the diameters of 500 etch pits. Figure 2 shows the diameter distribution. The step width of the diameter determination was 0.25 μm. The full width at half maximum (FWHM) of the ^{210}Po peak was 54 keV, and the FWHM of the asymmetric peak of ThC was 71 keV. The peaks were at the 6.05 and 6.09 MeV emission energies. The FWHM of the 0.65 major peak was 46 keV. At lower emission energies, a drop in resolution caused by the increase in specific energy loss can be expected.

Using this method the energy resolution is influenced by the specific energy loss, the range straggling, the evenness of the sheet thickness, the etching process, and the microscopic

measurement. Specific energy loss and range straggling depend on the energy of the particle. The evenness of the sheet thickness has to be better than ± 0.2 μm. Under the conditions described here the contribution of the etching process and the microscopic measurement amounts to 40 keV for the ^{210}Po peak and 33 keV for the ThC major peak.

Eocene echinoids and the Drake Passage

AUSTRALIA and Antarctica separated about 50 million years (Myr) ago[1]. Echinoid populations indicate a warmer climate at the time of separation than later. A model of oceanic circulation in the Southern Hemisphere, consistent with this observation, leads to a more precise dating of the opening of the Drake Passage between South America and Antarctica.

The oldest echinoid fauna known from the opening seaway between Australia and Antarctica has been preserved at several localities between Albany and Adelaide. The fauna is most abundant and best known in the Late Eocene Tortachilla Limestone, which outcrops along the eastern flank of the St Vincent Basin, south of Adelaide. Eighteen species of echinoids have been described from this formation of small lateral extent and a further five have yet to be described. The marsupiate echinoids, which are intermittently common in the Tertiary of southern Australia, are notably absent. Echinoids are also abundant a little further up the section at a Late Eocene horizon, low in the Port Willunga Beds. Less than 10 species are known at this level, and almost all are of genera different from those in the earlier Tortachilla. They include the earliest of the Australian marsupiate echinoids, the temnopleurid *Paradoxechinus stellatis* Philip and Foster.

A similar situation exists on the opposite flank of the basin. There is a complete change in the echinoid fauna between the Muloowurtie Formation and the overlying Rogue Formation in which *P. stellatis* appears.

By analogy with recent Antarctic brood-protecting echinoids, it has been inferred that the marsupium, developed in the female of several species of Australian Tertiary Temnopleuridae, Clypeasteroida and Spatangoida, confers an advantage in colder water[2]. An unsatisfactory aspect of correlating the presence of marsupiate echinoids with cold water is that the earliest fauna of the discussed region contains no marsupiate echinoids—despite the fact that this fauna probably lived more than 20° further south than its present position. Marsupiate echinoids are, in fact, a conspicuous component of the fauna during the journey of Australia towards the tropics.

Frakes and Kemp[3] proposed a model of early Tertiary climates which may provide the answer. In the Eocene there was no circumpolar cold current in the Southern Ocean because of the presence of a continuous Andean–West Antarctic mountain chain. As Australia was far to the south of South-east Asia, ample room existed for the southern equatorial current of the Pacific to continue into the Indian Ocean, sweep south and return, at least in part, through the new seaway which separated Australia from Antarctica. Because of the long time spent travelling through about 200° of longitude in the tropics, the equatorial current, which left the coast of South America at about 19° C. began its southerly sweep into the Indian Ocean at about 37° C. It was probably still above 20° C as it passed along the southern coast of Australia. A warm water echinoid fauna can therefore be expected. By the mid-Oligocene, the northward drift of Australia had restricted the flow of warm equatorial Pacific water into the Indian Ocean. More important, the breaching of the Andean–West Antarctic mountain barrier allowed a circumpolar cold current to replace the warm current in the widening seaway between Australia and Antarctica. The water temperature probably fell to well below 10° C. A changed echinoid fauna, including brood-protecting species, is consistent with this model.

Dalziel and Elliot[4] estimate the opening of Drake Passage, and thus the beginning of the circumpolar current, to have occurred between the latest Cretaceous (65 Myr) and about 25 Myr ago.

The Tortachilla Limestone was deposited at the beginning of the Late Eocene, probably high in P15 in the planktonic foraminiferal zonation[5]. The Port Willunga Beds have been sampled and dated[6] especially to provide a time framework for the sequence of echinoids, and the horizon containing *P. stellatis* has been placed high in the Late Eocene, corresponding to P17.

Using ages attributed to the planktonic foraminiferal datum planes[5] as a guide, the event which caused the replacement of a warm water by a cold water echinoid fauna in the seaway between Australia and Antarctica can be dated at about 40 Myr—probably 41–36 Myr. This event was probably the inception of the mighty Antarctic circumpolar current, which began with the breaching of the Andean–West Antarctic Cordillera and the concomitant creation of the Drake Passage. Thus, there is indirect evidence which enables the separation of South America from Antarctica to be more precisely dated than before.

Closing of the Protocadic Ocean and intraplate basins

THE presence of several long-lived, deeply subsiding basins, autogeosynclines[1], such as those in Michigan, Illinois, North Kansas and Williston suggests that the North American craton or plate remained in a constant position relative to the underlying mantle during the Palaeozoic.

In the Michigan Basin the Precambrian basement surface subsided about 4,000 m between the late Cambrian and the Devonian[1–6]. Throughout this time, there was little deposition of terrigenous sediment and subsidence was largely independent of loading. With a few exceptions, the isopachs of many of the series and stages within the basin are centred to the west and north of Saginaw Bay, a little to the north-east of the centre of the structural basin[7]. However, during the mid-Ordo-

vician there was more subsidence in the south-east[3], than elsewhere and during the early Silurian, the subsidence was suppressed, and carbonate reef belts extended along the northern and southern margins of the basin[8,9]. The rates of subsidence, relative to periods of deformation in the Taconian–Acadian orogenic belt to the east, are not known. Other intraplate basins subsided differentially over long periods of time, but not to such great depths.

The subsidence of the Michigan Basin caused, or resulted in, the displacement of a great volume of crustal material. It is not known whether the Moho was depressed or even if it is still deeper than in surrounding areas. The origin of domes[10] can be attributed to the expansion of crustal rocks above rising convection currents which heat the base of the crust. The formation of downward expanding convection cells is perplexing, but something like that occurred. The fact that the centre of subsidence was more or less fixed geographically seems to indicate that the crust did not move relative to the mantle under the North American plate. Therefore, the deep subsidence must have had a subcrustal cause.

It is believed that the ocean on the eastern margin of the North American craton resulted from the separation of the European and North American plates. It is usually called the 'proto-Atlantic' ocean[11], but I prefer to call it the Protacadic Ocean in reference to its closing during the Taconian–Caledonian–Acadian orogenies[13,17]. It is not the progenitor of the present Atlantic, and the term 'proto-Atlantic' has been applied more logically to the opening of the present South Atlantic Ocean during the early Mesozoic. The Dunnage Melange in north-eastern Newfoundland formed in a subduction zone in which the oceanic plate passed beneath the North American plate to the north-west[12-14]. Island-arc volcanics are represented in the Summerford Group to the north[15]. South of the Dunnage fault-bounded block, the Campbellton sequence of mafic volcanic rocks, manganiferous chert and greywacke flysch may represent ocean floor[16,17] and the better displayed Snooks Arm Group farther west has been attributed to oceanic crust[18,19].

During the early Palaeozoic the European plate does not seem to have had any deep autogeosynclines like those in North America[20]. The total subsidence of a trough through the middle of the European platform is only a tenth of that which occurred in the Michigan Basin over a similar time and there is no specific centre of sinking in this much larger area.

It is suggested that the autogeosynclines in the North American plate were linked to the underlying mantle, as is the case with modern plumes[21]. Both the plate and the mantle retained a fixed geographical position for about 100 Myr during the early Palaeozoic. The European plate moved over the mantle toward the North American plate, closing the Protacadic Ocean. The North American palaeomagnetic pole position for the Ordovician is very close to the Upper Palaeozoic position, which supports this hypothesis; however, it moved to lower latitudes during the Silurian, if the records are correctly interpreted[22].

Seismic refraction experiment on the Mid-Atlantic Ridge in the FAMOUS area

WE report results from ocean bottom seismographs (OBS)[1] and sonobuoys, in which unreversed refraction lines have been shot along and across the median valley of the Mid-Atlantic Ridge. P-wave arrivals indicate a structure under the median valley with layer 2 overlying 7.3 km s^{-1} mantle. Under the mountains on the ridge crest P and S arrivals suggest that layer 2 overlies layer 3, which in turn overlies 7.3 km s^{-1} mantle.

There are still relatively few determinations of the seismic velocity structure under the Mid-Atlantic Ridge[2-4] and only one has been reported[5] shot within the confines of the median valley. On geological grounds, Cann[6] has proposed the existence of a magma chamber situated at the top of a rising column of the asthenosphere at a depth of 3–4 km beneath the median valley. Francis and Porter[1] suggested that the postulated magma chamber could account for seismological results at 45° N. Seismologists[7-9] working with teleseismic data from earthquakes near the Ridge axis have reported a sharply bounded zone of low Q in the upper mantle beneath the axis, a 'gap in the lithosphere' across which S_n is not propagated.

A straight, but narrow section of the median valley bounded by fracture zones was chosen for this work and three OBS were laid, 10 km apart. Two were in the median valley and one on the mountains on the ridge crest to the east (Fig. 1). The tape recorder in OBS1 jammed, so no records were obtained from it. Three lines of near-surface shots were fired: A and B across the valley, perpendicular to the structure, and C along it. Line A (16 shots) was 37 km long, line B (16 shots) 36 km and line C (14 shots) 30 km. It was anticipated that the structure beneath the median valley would change near the fracture zones, so care was taken not to extend line C as far as them. For line C two recording sonobuoys were laid one mile apart straddling the position of OBS1, and for lines A and B two were laid, also one mile apart, over OBS3. The buoys drifted less than one mile from the laying position and during the shots along line C they stayed over the median valley the whole time.

Topographic correction is clearly necessary although a true scale section along lines A and B shows that the structure is not impossibly rugged. Arrivals have been corrected for a mean depth of 2.64 km (1,445 fathoms), assuming that the rock layering follows the sea floor. The times at the OBS and the sonobuoys have been corrected to the sea surface.

The results obtained by fitting least-squares straight lines to the first arrivals on the time distance diagrams are shown in Table 1. The weighted means of the apparent velocities are 4.91 $\pm$ 0.12 (layer 2), 6.64 $\pm$ 0.08 (layer 3) and 7.26 $\pm$ 0.06 ('mantle').

The data for both lines A and B from OBS3 and the sonobuoys fit together well when plotted on one time–distance

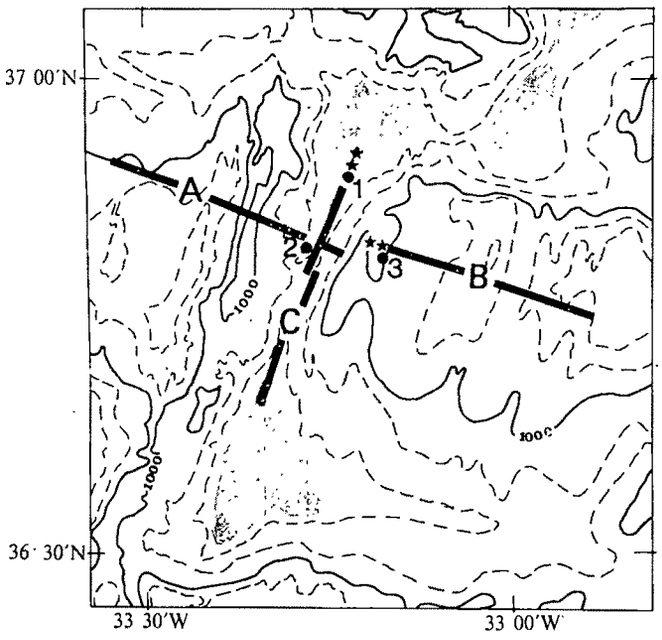

Fig. 1 Bathymetric chart showing the median valley, from an unpublished chart by J. D. Phillips, Woods Hole Oceanographic Institute. Contour interval 200 fathoms. Shaded areas are deeper than 1,500 fathoms. Dots, positions of OBSI, 2 and 3, stars, approximate positions of sonobuoys; Lines A, B and C, approximate track of ship during the firing of surface charges.

diagram, and the velocities and intercepts for the combined data for each line are within the limits of error of those obtained for the receivers treated separately. It is surprising that a similar statement applies to the sonobuoys and OBS2 for line C, considering that the receivers were 10 km apart. This suggests that the gross structure is more level, planar and homogeneous than may have been expected. No more than two refractors were detected on any line and the velocity and intercept of the upper one is not well determined and may be variable. Paths which cross the median valley, line A into OBS3, line B into OBS2, and line C, all detect a velocity of 7.3 km s^{-1} as the deepest refractor; paths which do not cross the median valley, line A into OBS2, and line B into OBS3, detect 6.6 km s^{-1} as the deepest refractor. The structure under the median valley is shown in Table 2*a*; it corresponds very well with the axial structure suggested by Le Pichon *et al.*[2]. The fact that the layer 3 velocity, 6.6 km s^{-1}, was detected under the flanks of the Ridge, should be treated with caution because the lines were not reversed and lateral velocity changes are to be expected. The detection is, however, consistent with the work of Keen and Tramontini[4] who found evidence of the presence of layer 3 within 20 km of the axis at 45° N.

Table 1 P-wave arrivals

Line	Receiver	Velocity* (km s^{-1})	Intercept* (s)	*N*
C	Sonobuoys and OBS2	5.17 ± 0.51	3.72 ± 0.13	11
		7.19 ± 0.09	4.37 ± 0.03	24
C	Sonobuoys	4.21 ± 0.46	3.35 ± 0.21	5
		7.34 ± 0.09	4.45 ± 0.04	19
A	Sonobuoys and OBS3	5.09 ± 0.39	3.60 ± 0.12	12
		7.33 ± 0.17	4.45 ± 0.05	31
B	OBS2	7.42 ± 0.21	4.68 ± 0.10	12
A	OBS2	4.41 ± 1.13	3.50 ± 0.38	6
		6.75 ± 0.26	4.12 ± 0.11	6
B	Sonobuoys and OBS3	5.02 ± 0.36	3.59 ± 0.10	12
		6.57 ± 0.17	3.99 ± 0.07	24

N is the number of points to which the line was fitted. Only the hydrophone traces from the OBS were used.
* Intercepts and velocities are quoted with their standard errors.

Table 2 Structures

	Line	Velocity (km s^{-1})	Thickness (km)
a	C	1.5	2.64
	Sonobuoy and OBS2	[2.8]	0.58
		5.17	2.05
		7.19	
b	A	1.5	2.64
	OBS2	[2.8]	0.35
		4.41	1.34
		6.75	
c	B	1.5	2.64
	Sonobuoy and OBS 3	[2.8]	0.39
		5.02	1.20
		6.57	

Brackets enclose assumed velocities[5].

Whitmarsh concludes, from shots at almost the same location as line C, that layer 3 is present at the ridge axis under the median valley[5]. This may be because the direct water wave arrival on his records has obscured the crossover between the 5.2 km s^{-1} and 7.2 km s^{-1} lines, causing him to fit just one line to these two sets of points. If one line is fitted to the 35 points on our time–distance diagram we obtain a velocity of 6.5 ± 0.12 km s^{-1} and an intercept time of 4.06 ± 0.04 s, which is similar to Whitmarsh's result.

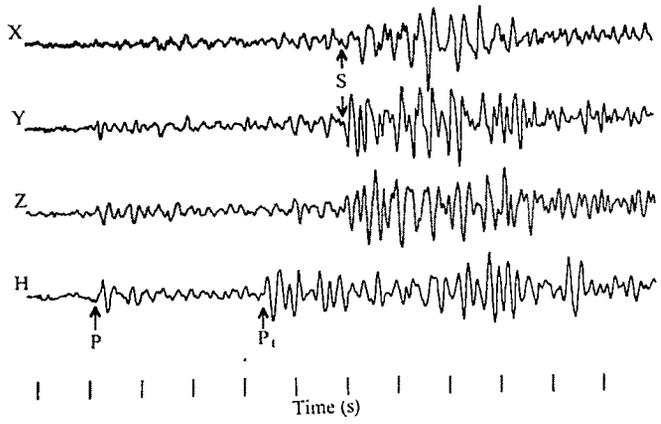

Fig. 2 Record from OBS2 of a shot on line B fired at a range of 36 km.

Table 3 Shear-wave arrivals

Line	Receiver	Velocity* (km s^{-1})	Intercept* (s)	*N*
C	OBS2	3.32 ± 0.63	4.16 ± 0.78	5
A	OBS3	3.96 ± 0.19	5.03 ± 0.31	8
B	PBS2	4.08 ± 0.13	5.49 ± 0.22	9
A	OBS2	4.03 ± 0.12	5.03 ± 0.13	7
B	OBS3	3.82 ± 0.64	5.11 ± 0.92	6

N is the number of points to which the line was fitted.
* Intercepts and velocities are quoted with their standard errors.

A typical record of S waves is shown in Fig. 2. Arrivals are visible on both OBS2 and OBS3 for shots fired at ranges greater than 10 km. The results of fitting least-squares lines to the data are shown in Table 3. It can be seen that there are no significant differences between them. The weighted mean velocity is 4.02 ± 0.05 km s^{-1}. Model calculations using the structures suggested by the P-wave arrivals and assuming a V_p/V_s ratio of $\sqrt{3}$ indicate that the arrivals are consistent with waves transformed to a shear wave at the seafloor and propagated as a head wave in the 7.3 km s^{-1} layer. There is no evidence for a lower velocity on lines A into OBS2 and B into OBS3, on which the highest P-wave velocity was 6.7 km s^{-1}, which could

suggest that the 7.3 km s^{-1} layer underlies layer 3 there. Nor is there any evidence for a velocity of about 2.8 km s^{-1}, corresponding to shear waves propagating in layer 2.

We thank T. J. G. Francis and I. T. Porter for the OBS records, R. B. Whitmarsh for constructive discussion and all those who helped aboard *RRS Shackleton.*

Clays and formation of deep-sea chert

CHERT in the Pacific, Atlantic, Indian and Southern Oceans occurs both as nodules and as layers or lenses[1]. Associated sediments include carbonate, biogenous silica, brown clay and volcanic ash. Chert is usually found in Middle Eocene or older sediments; the actual time of chert formation is, however, not known.

Biogenous opal is the principal source of silica for the formation of chert[1,2]. Silica may also be produced by the alteration of volcanic detritus, resulting in the mineral assemblage smectite, zeolite and opal[3,4]. A third possible source, not previously suggested in the literature, is the submarine diagenesis of clay minerals. Alteration of a smectite to hydrous mica or chlorite would release silica. The formation of secondary chert by the subaerial transformation of a ferric-rich smectite to kaolinite has been described by Altschuler *et al.*[5], and several studies have shown that hydrous mica (illite) and chlorite become dominant at the expense of other clay minerals with increasing age[6].

A 9-meter piston core (Scan 16P) taken from a depth of 5,597 m, 16° 25′N 164° 24′W, containing a stiff, homogenous, brown zeolitic clay with a porcellanite layer at 436 cm, has been studied. The age of the sediment was determined from radiolaria to be Middle Eocene. Seismic profiles from the area show an upper, probably chert, reflector at 30–40 m.

The brown clay has a sharp contact with the porcellanite layer and was identified by X-ray diffraction as smectite with minor hydrous mica. Using the X-ray diffraction opal classification of Jones and Segnit[7], the radiolaria are opal-CT with quartz, and the porcellanite is opal-A and opal-CT. Optically, the quartz is chalcedony and forms internal moulds of radiolaria tests.

Scanning electron microscope examination revealed that the outer borders of the porcellanite layer have a botryoidal surface, composed of opal-A and radiating needles of opal-CT. Internally, the porcellanite layer is porous, massive opal-CT, with clay rosettes within the pores (Figs 1 and 2).

Fig. 1 Rosettes of hydrous mica filling the pores in porcellanite (opal–CT). SEM photomicrograph. Scale bar, 10 μm.

Using a transmission electron microscope, an electron diffraction pattern of a well crystallised clay particle was obtained. The *d* spacings of the clay were calculated from several diffraction patterns (4.46 (020,110), 3.30 (022,003), 2.59 (200,131), 2.32 (201,132), 1.97 (005), 1.48 (060,331) ± 0.05 Å) and closely matched those of hydrous mica[8,9].

Evidence which suggests that the mineral is a hydrous mica was also obtained with the electron microprobe. A traverse across a fracture surface of the porcellanite, measuring the presence and relative abundance of aluminium and potassium in the blue luminescent clay gave the results shown in Fig. 3, and the ratio of silicon to aluminium was measured as 1.2. No magnesium, and only a trace of iron, was detected in the clay. A sample of the smectite from the surrounding sediment was also analysed and had a substantially higher silicon to aluminium ratio of 3.4 and a magnesium to iron ratio of 0.8.

The dominant clay mineral in the surrounding sediment is a magnesium–iron smectite and in the porcellanite layer it is a hydrous mica. This distribution, in conjunction with the evidence discussed, suggests a relationship between

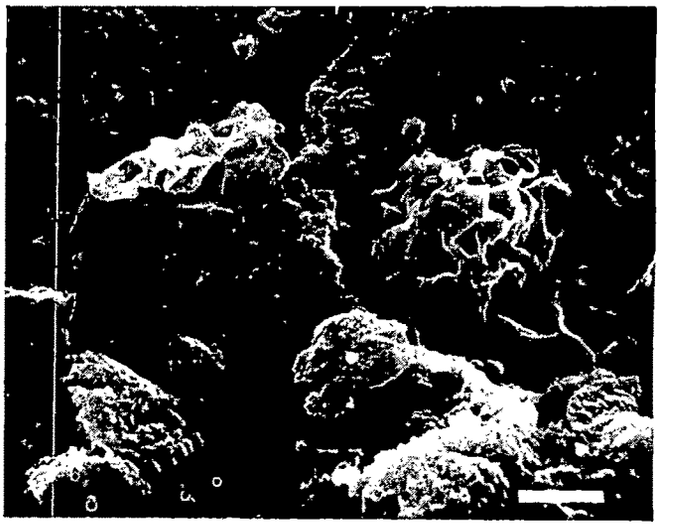

Fig. 2 SEM photomicrograph of porcellanite fracture surface and hydrous mica rosette. Scale bar, 2 μm.

the diagenetic reaction of smectite to hydrous mica and the formation of chert. The habit and distribution of the hydrous mica in the porcellanite layer strongly suggest that it is authigenic, and its formation from a smectite would release large quantities of silica. A release of silica is strongly indicated by the different silicon–aluminium ratio in the smectite and the authigenic hydrous mica. Aluminium is assumed to remain conserved during the reaction.

The actual amount of silica released depends on the chemical composition of the smectite and hydrous mica. For example, it can be calculated that the stoichiometric transformation of 10 g of montmorillonite could produce 6.4 g of hydrous mica and 3.3 g of quartz. These proportions do not, however, have to be represented within the same sedimentary layer. Assuming that all the silica released is precipitated, the amount of pelagic brown clay that would have to alter in the core can be calculated. The brown clay has an approximate porosity of 60%, and smectite composes 60% by weight of the solid phases, and the porcellanite layer has approximately 40% by volume opal-CT (density 2.4 g cm^{-3}). If the smectite has the ideal montmorillonite composition and it all alters, a sediment layer 0.4 cm thick could produce the silica for a 0.1 cm porcellanite layer. The important problems of why the porcellanite layer formed where it did and the mechanism and kinetics of the reaction are still being studied. Seawater is the most probable source of potassium. Based on a 60% porosity and on a conservative diffusion rate of 10^{-7} cm^2 s^{-1},

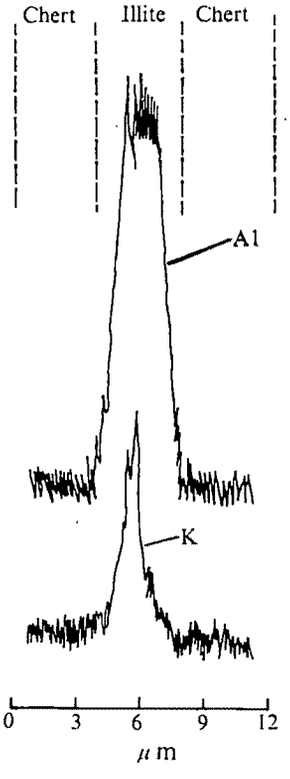

Fig. 3 Relative abundances of aluminium and potassium from an electron microprobe traverse across a fracture surface similar to Fig. 2.

all the potassium necessary to convert a montmorillonite layer of 0.4 cm into hydrous mica in the porcellanite layer, will be supplied in 20 yr. The high mobility of magnesium might account for the lack of a diagenetic phase rich in magnesium. Because of the low mobility of iron, the transformation of montmorillonite rich in iron to hydrous mica poor in iron should result in a higher concentration of iron oxide or hydroxide in the surrounding sediments. The studied core was, however, rich in iron oxide throughout, making it difficult to prove such an enrichment.

The proposed mechanism of chert formation could be further supported by measuring the $^{18}O/^{16}O$ ratios of the coexisting hydrous mica and opal-CT. In addition, a separation of the hydrous mica could be dated to give the actual time of formation of the porcellanite, assuming argon is retained in the structure.

We thank Professor G. Arrhenius and Professor E. L. Winterer for criticism. The work was supported by the Office of Naval Research and by grants from the International Nickel Company, Inc. to the Institute of Marine Resources, Scripps Institution of Oceanography.

BIOLOGICAL SCIENCES

Terminal deoxynucleotidyltransferase in murine plasmocytomas

FOUR different DNA polymerases have so far been described in animal cells. Two of them are present in all types of cells[1-5]: the low molecular weight nuclear DNA polymerase, and the high molecular weight cytoplasmic DNA polymerase. The concentration of only the latter varies during the cell cycle, suggesting its involvement in DNA replication[6]. The two other DNA polymerases seem to exist only in certain cell types: the first, recently characterised[7], seems to be directed by RNA, although differing from the oncornavirus reverse transcriptase[8]; the second is terminal deoxynucleotidyltransferase which does not exhibit the usual properties of DNA polymerases since it catalyses the polymerisation of deoxyribonucleotides in the absence of template by adding them randomly to the 3'OH end of oligo- or polydeoxyribonucleotides[9,10]. This last enzyme is tissue-specific: it exists only on the thymus of the different species tested[11]. Recently the terminal transferase was also identified in blood lymphoblasts of a child suffering from acute lymphoblastic leukaemia[12].

In addition to the DNA polymerase activities already described in murine plasmocytoma cells[13], we have found in the course of our studies[14] that these tumours also contain terminal deoxynucleotidyltransferase.

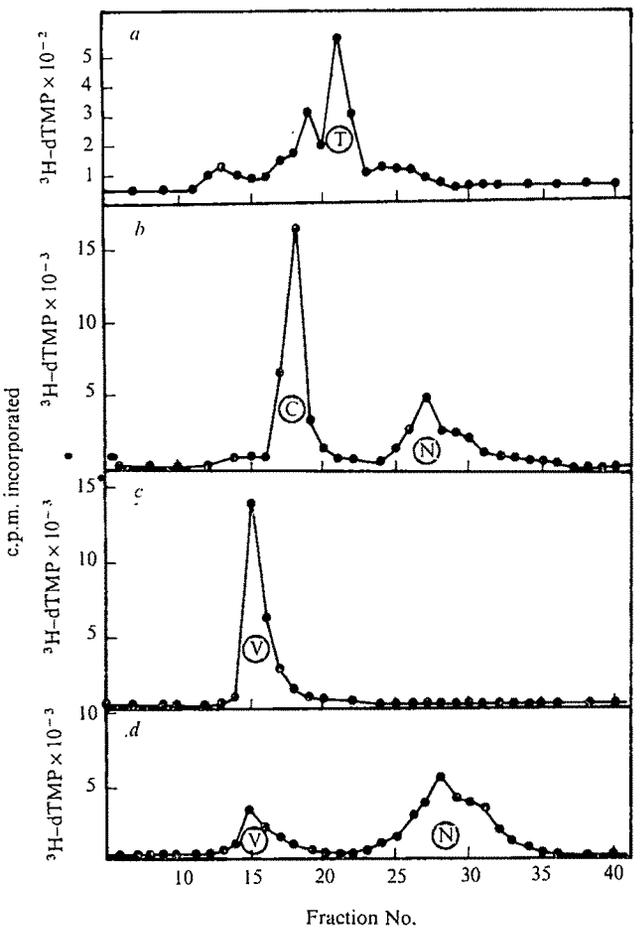

Fig. 1 Phosphocellulose chromatography of DNA polymerase activities from murine plasmocytoma MOPC 173 extracts. Subcutaneous tumours (2 g) were washed repeatedly in phosphate-buffered saline. After three cycles of freeze-thawing, they were homogenised by 10 strokes of a Teflon-glass motor-driven homogeniser in two volumes of TEM buffer (0.05 M Tris-HCl *p*H 7.9, 1 mM EDTA, 2.8 mM 2-mercaptoethanol). The homogenate was diluted in TEM buffer to 20 ml and Nonidet P40 was added (0.5% final). After slow mixing during 15 min at 0° C, the detergent-treated homogenate was centrifuged at 100,000*g* for 1 h. The *p*H of the supernatant was lowered to 5 by dropwise addition of 1 M acetic acid. The *p*H 5 precipitate was collected by centrifugation at 30,000*g* for 10 min, and redissolved in a minimal volume of TEMG buffer (TEM buffer containing 20% glycerol). The protein concentration of the *p*H 5 extract was adjusted to 2 mg ml^{-1} and 10 ml were applied to a P11 phosphocellulose column (10 × 1.2 cm). After a 40 ml wash by TEMG buffer containing 500 μg ml bovine serum albumin (TEMG-BSA), the adsorbed proteins were eluted by an 80 ml gradient of 0–1 M KCl in TEMG-BSA, at a flow rate of 10 ml h^{-1}. Fractions of 2 ml were collected, and assayed for DNA polymerase activities. DNA polymerase assays were performed with 25 μl of each fraction in a final volume of 100 μl for 1 h at 37° C. Depending on the template primer used, the incubation mixture contained: *a*, d(pT)$_4$-primed reaction: 5 μmol of Tris-HCl (*p*H 7.4), 0.2 μmol of dithiothreitol, 0.08 μmol of Mn^{2+} (chloride), 0.3 A_{260} unit of d(pT)$_4$ (Collaborative Research) and 250 pmol of ^{3}H-dTTP (2,000 c.p.m. pmol^{-1}). *b*, Activated DNA-primed reaction: 5 μmol of Tris-HCl (*p*H 7.9), 0.2 μmol of dithiothreitol, 1 μmol of Mg^{2+} (chloride), 0.2 A_{260} unit of activated calf thymus DNA[20] 5 nmol each of dATP, dGTP, dCTP and 200 pmol of ^{3}H-dTTP (4,000 c.p.m. pmol^{-1}). *c*, rA$_n$·dT$_{10}$-primed reaction : 5 μmol of Tris-HCl (*p*H 7.9), 0.2 μmol dithiothreitol, 0.1 μmol Mn^{2+}(chloride), 0.02 A_{260} unit of rA$_n$·dT$_{10}$ (Boehringer) and 1 nmol of ^{3}H-dTTP (500 c.p.m. pmol^{-1}). *d*, rA$_n$·dT$_n$-primed reaction: as *c*, with 0.025 unit of rA$_n$·dT$_n$ (Miles) in place of rA$_n$·dT$_{10}$. The acid-precipitable material was collected by filtration on Millipore filters and the radioactivity was counted in a Nuclear Chicago scintillation spectrometer. Each panel represents the results of the assays of the fractions of the same column, using one of the above template primers.

We used three different murine plasmocytomas: MOPC 173 and its two cell lines MF_2 and ME_2[15], TEPC 15[16] and MOPC 315[17]; as control cells we used normal BALB/c mouse thymi, spleens from BALB/c nude mice, and L cells. The enzyme was detected using a method similar to that of McCaffrey *et al.*[12]: the cell homogenate was treated by a nonionic detergent, centrifuged at 100,000*g* and the pH of the supernatant was lowered to 5. The precipitate was solubilised and fractionated by chromatography on a phosphocellulose column. The elution profile from MOPC 173 is presented in Fig. 1 and from TEPC 15 in Fig. 2; MOPC 315 gave similar results. These profiles were obtained by assaying the protein fractions eluted from the column in conditions which discriminate between the different DNA polymerases by their ability to use specific template primers (Table 1). Plasmocytoma cells produce viral particles (type A and type C), and contain reverse transcriptase.

Table 1 Primer specificity of DNA polymerases from MOPC 173 tumours

Template-primers	DNA polymerases	MOPC 173 tumour enzymes* V (0.28 M)	C (0.35 M)	N (0.55 M)	C-type particles
rA$_n$·dT$_n$ (^{3}H-dTTP)		5·75	1·6	6·7	52
rA$_n$·dT$_n$ (^{3}H-dATP)		0·06	0·70	0·02	0·00
rA$_n$·dT$_{10}$ (^{3}H-dTTP)		12·2	0·47	0·00	65
dA$_n$·dT$_{10}$ (^{3}H-dTTP)		0·02	1·42	7·20	0.00
rC$_n$·dG$_{10}$ (^{3}H-dGTP)		4·60	0·45	0·00	50

*Molarity of elution from phosphocellulose

The assays were performed under the conditions described as in Fig. 1, with 20 μl of each phosphocellulose fraction. Incubations were at 37° C for 30 min. Type C particles were purified from the supernatant of MOPC 173 cells in culture by sucrose gradients as described[14]; they were tested with 50 μg of virus proteins per assay. The 0·55 M phosphocellulose enzyme can use rA$_n$·dT$_{10}$ as template if the temperature is lowered to 30° C, but even under these conditions it cannot use rC$_n$·dG$_{10}$.

For all the cells tested, the polymerases, when present, were eluted from the column as follows: viral reverse transcriptase (0.28–0.3 M KCl: 'V' enzyme) high molecular weight C polymerase (0.35 M), terminal deoxynucleotidyltransferase (0.4 M: 'T' enzyme) and low molecular weight N polymerase (0.55 M.) The chromatogram shows some overlapping mostly between the first two enzymes. The separation between the C enzyme and terminal transferase is not always as satisfactory as in Fig. 1. Good resolutions were obtained when the 0.45 M KCl eluate from the phosphocellulose column (after a 0.25 M wash), was filtered on Sephadex G-150, the elution volume of terminal transferase being consistent with a molecular weight of about 30,000.

The thymus cells gave the same elution profile for terminal transferase as did the MOPC 173 cells. The complete results

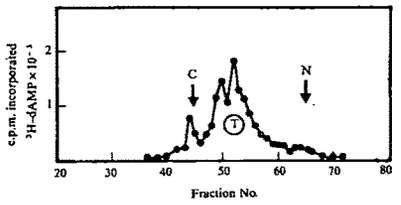

Fig. 2 Terminal deoxynucleotidyl transferase in TEPC 15 plasmocytoma tumours. The experimental procedure was the same as for MOPC 173 tumours (Fig. 1), with the exception of the fraction volumes (1 ml) and of the assay of the terminal transferase which was performed with d(pT)$_{10}$ (Boehringer) and ^{3}H-dATP (250 pmol 2,000 c.p.m. pmol^{-1}). The arrows represent the fractions containing the other DNA polymerases (detected as in Fig. 1).

Table 2 DNA polymerases present in murine tissues

Tissue	Reverse transcriptase V	High molecular weight polymerase C	Terminal-transferase T	Low molecular weight polymerase N
L cells	+	+	—	+
Athymic mouse spleen	—	+	—	+
Thymus	—	+	+	+
MOPC 173 (tumours)	+	+	+	+
MOPC 173 (cells in culture)	+	+	+	+
TEPC 15 (tumours)	+	+	+	+

Results were obtained by the method described in Fig. 1. Relative levels of activity are not shown.

summarised in Table 2 show that the terminal transferase is present only in thymus and plasmocytoma cells.

The properties of the terminal transferase extracted from plasmocytoma MOPC 173 are the same as those of the thymic enzyme: it uses different oligonucleotides as initiators ($d(pT)_4$, $d(pT)_{10}$, $d(pG)_4$ and $d(pA)_{10}$ were tested) and it polymerises separately each of the four deoxynucleoside triphosphates, with a better yield for dATP. A low self initiation takes place in the absence of initiator. Divalent cations are indispensable.

Since plasmocytoma cells are generally considered to be B cells[18], the presence of terminal transferase in these tumours was unexpected. McCaffrey *et al.*[12] pointed out that the presence of this enzyme in leukaemic lymphoblasts would denote a thymic origin. But, neither in the McCaffrey's description nor in our study, have thymus antigens been checked. In most plasmocytomas, θ antigen is lacking[18], whereas B antigen is present (E. Stockert, personal communication). Thus, it would seem plausible to assume that plasmocytoma cells represent an intermediate stage of differentiation between B and T cells, as has been previously proposed for a thymoma cell line [19]. Another hypothesis is that transformation by itself would have led to the derepression of terminal transferase. Further studies are needed before discussing these hypotheses in detail; work is in progress to check the complete set of antigens expressed on plasmocytoma cells; it would also be of interest to isolate the thymic cell population responsible for the terminal deoxynucleotidyltransferase activity.

Interaction between the antibiotic tyrocidine and DNA *in vitro*

Very little is known about the natural function of the peptide antibiotics. The production of antibiotics may be related to sporulation as only sporulating microorganisms produce antibiotics[1]. In general, the synthesis of antibiotics occurs within a limited time at the end of the logarithmic growth of cell cultures[2], concurrent with a change in the specificity of transcription[3]. Loss, through mutation, of the ability to synthesise the antibiotic leads to asporogeny, in some cases[1]. Specific inhibitors and changes in culture conditions affect both the synthesis of antibiotic and sporulation[4]. Sarkar and Paulus[5] demonstrated that the cyclic peptide antibiotic, tyrocidine, produced by *Bacillus brevis* (ATCC 8185) effects RNA synthesis *in vivo*, whereas DNA synthesis continues. Moreover, these authors give evidence that tyrocidine inhibited an *in vitro* RNA transcriptional system using *B. brevis* DNA and *B. brevis* DNA-dependent RNA polymerase. Complete inhibition of RNA synthesis with a tyrocidine concentration comparable to that in a *B. brevis* cell at the end of the vegetative growing phase was observed. A strong binding of the oligopeptide antibiotics, neotropsin and distamycin A, to double-stranded DNA, resulting in a pronounced heat stabilisation of the double-strands, has been reported[6]. Compared with pure DNA, these peptide-DNA complexes exhibit a low template activity[7].

In this report we describe experiments demonstrating that tyrocidine interacts *in vitro* with DNA. A complex formation between the initiation sites and tyrocidine is suggested as the mode of action.

RNA polymerase was isolated from a logarithmic growing cell culture of *B. brevis* (ATCC 8185) according to the method of Burgess[8] except that the polymerase was eluted from DEAE cellulose by a linear KCl gradient instead of stepwise. The enzyme, finally purified on a linear glycerol gradient, was tested for purity by polyacrylamide gel electrophoresis. The enzyme was at least 90% pure. SDS gel electrophoresis revealed three main components with molecular weights of about 45,000, 55,000 and 160,000, corresponding to the 2 αs, σ and β′β components of the polymerase respectively[9]. In addition there was an unknown component with a molecular weight of about 120,000 which has been already described by Sarkar and Paulus[9]. In contrast to the report of these authors, σ was not released during glycerol gradient centrifugation. This polymerase transcribed both *B. brevis* DNA and calf thymus DNA. In both cases transcription was inhibited proportionally by added tyrocidine. Complete inhibition was achieved when 20 μg tyrocidine was added to a 250 μl transcription assay containing 7 μg *B. brevis* DNA, or when 25 μg tyrocidine was added to the same system containing 2 μg calf thymus DNA. The tyrocidine concentration was thus similar to that which Sarkar and Paulus[5] found to be inhibitory in their transcription assay

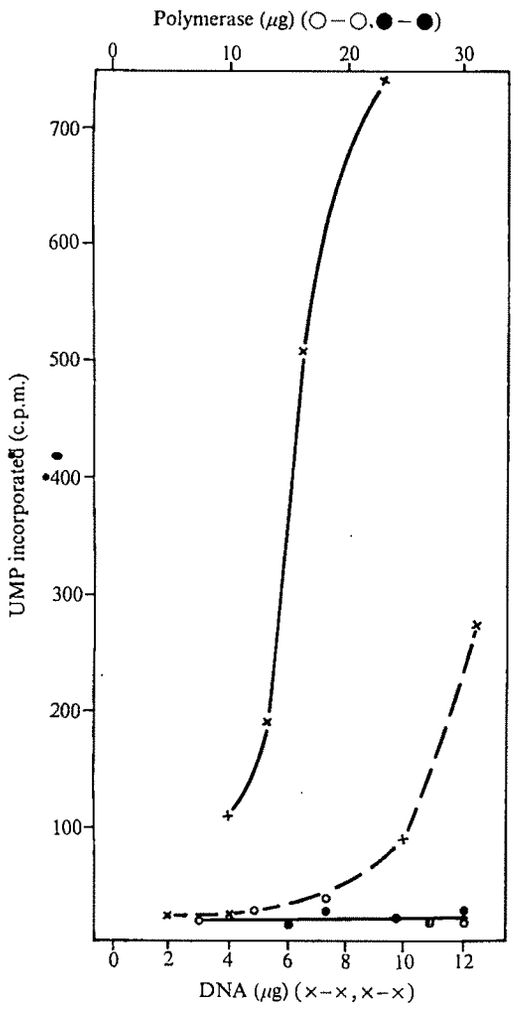

Fig. 1 Effects of DNA and of RNA polymerase on transcriptional system inhibited by tyrocidine. Transcription of 7 μg *B. brevis* DNA was inhibited by tyrocidine to 87%. To this system increasing amounts of *B. brevis* DNA were added (×—×). In parallel transcription was inhibited to 100% and increasing amounts of RNA polymerase were added (●—●). Transcription of 2 μg calf thymus DNA was inhibited by tyrocidine to 100%. To this system increasing amounts of calf thymus DNA (× – – ×) or RNA polymerase (O—O) were added. Polymerase was isolated from cells grown in a rich medium (5 g peptone, 1.5 g yeast extract, 1.5 g beef extract, 3.5 g NaCl, 3.7 g K_2HPO_4, 1.3 g KH_2PO_4, 1.0 glucose in 1,000 ml of water) and collected during exponential growth. Polymerase was purified according to Burgess[8] including the glycerol gradient step. The enzyme contained the σ subunit and was completely dependent on DNA. An incorporation of 16.3 pmol of UMP into RNA in the presence of 3.5 μg *B. brevis* DNA was catalysed by 1 μg of RNA polymerase within 30 min. *B. brevis* DNA was purified by treating cells with lysozyme (10 μg ml^{-1}) for 5 min at 37° C followed by SDS treatment (0.2% sodium dodecyl sulphate in 0.1 M EDTA, 0.4 M NaCl, *p*H 7.8) at room temperature for 15 min. Protein was removed by phenol extraction. RNA was digested by RNase treatment (50 μg ml^{-1}) for 90 min followed by pronase treatment (100 μg ml^{-1}) for 180 min. Pronase was removed by phenol extraction. The DNA was finally purified by CsCl density centrifugation. Calf thymus DNA (Serva) was used without further purification. Transcription assays were carried out at 37° C for 30 min in the presence of 0.03 M Tris-HCl, *p*H 7.9, 0.15 M KCl, 0.005 M $MgCl_2$, 0.1 mM EDTA, 0.001 M 2-mercaptoethanol, 0.02 M each of ATP, GTP and CTP and 0.5 μC ^{3}H-UTP (52 Ci $mmol^{-1}$). For each assay (250 μl) 6 μg polymerase and 7 μg *B. brevis* DNA or 2 μg calf thymus DNA were used. Tyrocidine (Serva) was dissolved in methanol (2 mg ml^{-1}) and added to the assays. Transcription was terminated by adding cold trichloroacetic acid to a final concentration of 7%. The precipitates were collected on glass fibre filters (Whatman GF/C), washed with trichloroacetic acid and ethanol, dried and counted in a Nuclear Chicago liquid scintillation counter.

and was comparable to that in a *B. brevis* cell during the late logarithmic phase. The solvent used for tyrocidine, methanol, had a slightly stimulatory effect on RNA synthesis. Therefore the inhibition was not due to the solvent. When *B. brevis* polymerase was replaced by *Escherichia coli* RNA polymerase a comparable inhibition was obtained. Thus tyrocidine does not act only on the homologous DNA or on the homologous polymerase.

When increasing amounts of DNA were added to an inhibited transcription system, transcription could be restarted. In contrast, RNA polymerase did not affect an inhibited transcription system. This was the case for *B. brevis* DNA as well as for calf thymus DNA (Fig. 1). It is therefore likely that tyrocidine acts on DNA which is no longer accessible to the polymerase and that the polymerase is not affected by tyrocidine.

In the experiments described above, DNA was first mixed with tyrocidine, and the reaction started by the addition of polymerase. In other experiments transcription was allowed to proceed for some time before the addition of tyrocidine. In this case significant transcription ensued for a certain time after the addition of tyrocidine and was only later slowed down or stopped. A possible interpretation of this phenomenon, which was true for the *B. brevis* as well as for the calf thymus system, could be as follows: once transcription has started the transcribing polymerase cannot be stopped by tyrocidine. After terminating, however, no new initiation can occur because the initiation sites are blocked by the antibiotic. Following this interpretation, the target of tyrocidine would be the initiation of the transcription process.

To prove the hypothesis that tyrocidine interacts with DNA, complex formation has to be demonstrated. Sephadex G-25 gel filtration could not be used because tyrocidine adsorbs to the gel due to its high tryptophan content. A DNA-tyrocidine complex was detected by glycerol gradient

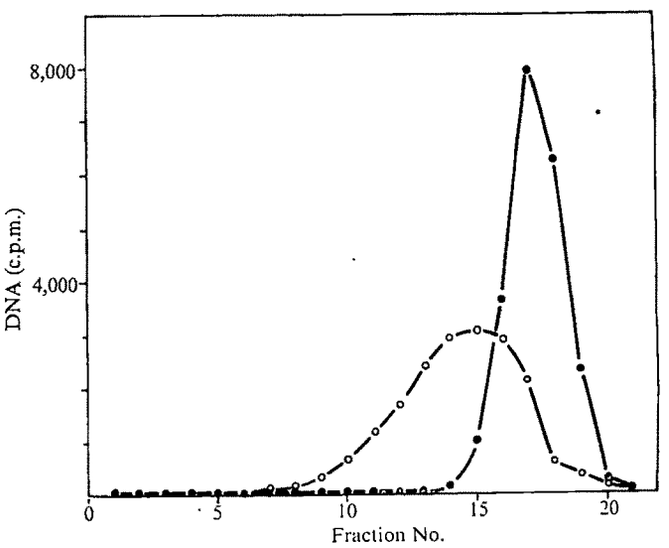

Fig. 2 Complex formation between *B. brevis* ^{3}H-DNA and tyrocidine (O—O) assayed by glycerol gradient centrifugation. ^{3}H-DNA was isolated from *B. brevis* cultures which have been incubated with 1 μC ^{3}H-adenine (specific activity 21 Ci $mmol^{-1}$) per ml for several generations. Cells were broken and DNA purified as described in Fig. 1 except that the CsCl-purification step was omitted. The specific radioactivity of the DNA was 3,100 c.p.m. μg^{-1}. A mixture of 20 μg ^{3}H-DNA and 20 μg tyrocidine in 0.01 M Tris-HCl *p*H 7.8. 0.005 M $MgCl_2$, 0.01 M KCl was incubated for 10 min at 25° C. The complex was then layered on to a 14 ml 10–30% (v/v) glycerol gradient in buffer as above and centrifuged in a SW 27.1 rotor (Beckman, Spinco Ultracentrifuge) at 25° C for 12 h at 26,000 r.p.m. At the end of the run the gradient was fractionated, the DNA precipitated by trichloroacetic acid, and the radioactivity estimated. DNA without tyrocidine (●—●) was run on a parallel gradient as a marker.

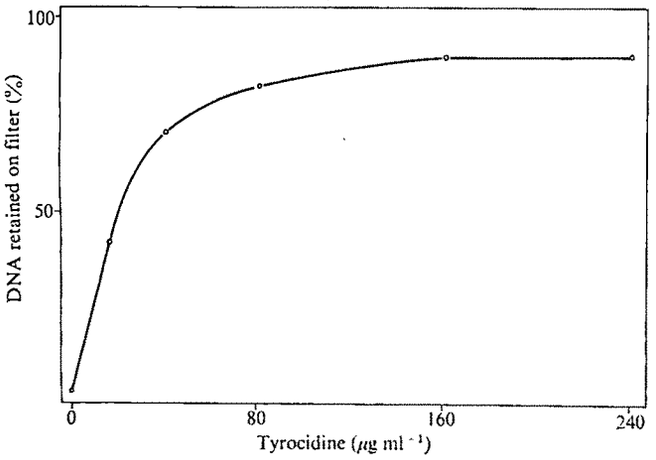

Fig. 3 Complex formation between *B. brevis* DNA and tyrocidine, assayed by the filter binding technique of Riggs *et al.*[10]. ^{3}H-DNA was isolated from *B. brevis* cultures which had been incubated with 1 μC ^{3}H-adenine (specific activity 21 Ci mmol^{-1}) for several generations. In total volumes of 250 μl, 1.98 μg ^{3}H-DNA were incubated with increasing amounts of tyrocidine for 10 min at room temperature in a buffer containing 0.01 M Tris, *p*H 7.8, 0.01 M magnesium acetate, 0.01 M KCl, 0.0001 M EDTA, 5% dimethylsulphoxide and 50 μg bovine serum albumin ml^{-1}. The mixture was then filtered slowly through a nitrocellulose filter (MF 100, Schleicher and Schüll) and was washed once with 0.8 ml of the same buffer but without albumin. The filter was dried and counted in a liquid scintillation counter. Under the conditions described, only 2–4% of the DNA was held back on the filter in the absence of tyrocidine.

centrifugation. ^{3}H-labelled *B. brevis* DNA was incubated with tyrocidine at a concentration of 80 μg ml^{-1} and centrifuged through a glycerol gradient. The majority of the DNA incubated with tyrocidine sedimented more rapidly than the marker DNA (Fig. 2), demonstrating complex formation. At a concentration of 160 μg tyrocidine ml^{-1}, most of the DNA was found to be on the bottom, whereas at a concentration of 40 μg tyrocidine ml^{-1}, most of the DNA moved in the position of the marker DNA.

Another way to demonstrate DNA-tyrocidine complex formation is the nitrocellulose filtration method of Riggs and Bourgeois[10]. In this system double stranded DNA does not adsorb to the nitrocellulose filter. When a complex is formed between DNA and a peptide or protein, the DNA complex is retained on the filter. In these experiments ^{3}H-labelled *B. brevis* DNA was used. The amount of retained ^{3}H-DNA is a measure of the complex formed. Without tyrocidine only about 2–4% of the DNA was bound by the nitrocellulose filter. Figure 3 illustrates the complex formation at a constant ^{3}H-DNA concentration with increasing amounts of tyrocidine.

We tested the stability of the complex. To a complex of labelled DNA and tyrocidine, a 50-fold excess of cold *B. brevis* DNA was added and incubated for 1 h. At various times samples were withdrawn and filtered through nitrocellulose filters. It was found that 50% of the complex was broken down within 5 min, whereas the rest of the complex was almost completely stable for 1 h. It might be that about 50% of the initial complex detected on filters was a non-specific complex and was easily broken down. The remaining 50% stable complex might indicate a specific complex formation.

We conclude from our experiments that there is a complex formation between DNA and the antibiotic tyrocidine *in vitro*. Taking into account the observations from other laboratories, our results suggest that tyrocidine acts *in vivo* at the level of transcription by inhibiting the formation of polymerase-DNA complexes. This might reflect a control mechanism during the transition from the vegetative to the sporulating cell, when many of the genes active during vegetative growth are switched off. Yoshida *et al.*[11] came to similar conclusions working with a different system. They found that vegetative cell cultures of *Streptomyces antibioticus*, which produces actinomycin D, are sensitive to actinomycin D. But the cells are insensitive to the compound during the transition of vegetative growth to sporulation. It is not yet known how genes are transcribed in late logarithmic or stationary cells which contain a high concentration of tyrocidine or actinomycin D. Experiments investigating the behaviour of RNA polymerase from sporulating cells in the presence of tyrocidine are in progress.

The final evidence for a regulatory role of the peptide antibiotic has to come from DNA-tyrocidine complexes isolated from cells and exhibiting a qualitatively different template activity compared with the template from vegetative cells.

Activation of a C-type virus from the human carcinoma cell line HBT-3 by iododeoxyuridine and testosterone

WE report the activation of a C-type virus from the human carcinoma cell line, HBT-3, with iododeoxyuridine following a testosterone-induced cellular morphology change. We feel that this method will prove useful in activating endogenous C-type virus. Studies are in progress to further characterise the virus and determine the species of origin.

The human breast tumour cell line, HBT-3, has been described in some detail[1]. These cells have been maintained continuously as non-contact-inhibited epithelial cells (HBT-3Ep, Fig. 1*a*). The cells have a high cloning efficiency and an abnormal karyotype with three marker chromosomes. A DNA polymerase resembling the polymerase of RNA tumour viruses has been detected in this cell line[2]. No virus particles have been detected however by electron microscopy (EM) or in tissue culture supernatants banded on sucrose gradients (personal communication from R. Bassin).

The induction of mammary carcinomas in the mouse results from an interaction between the murine mammary tumour virus

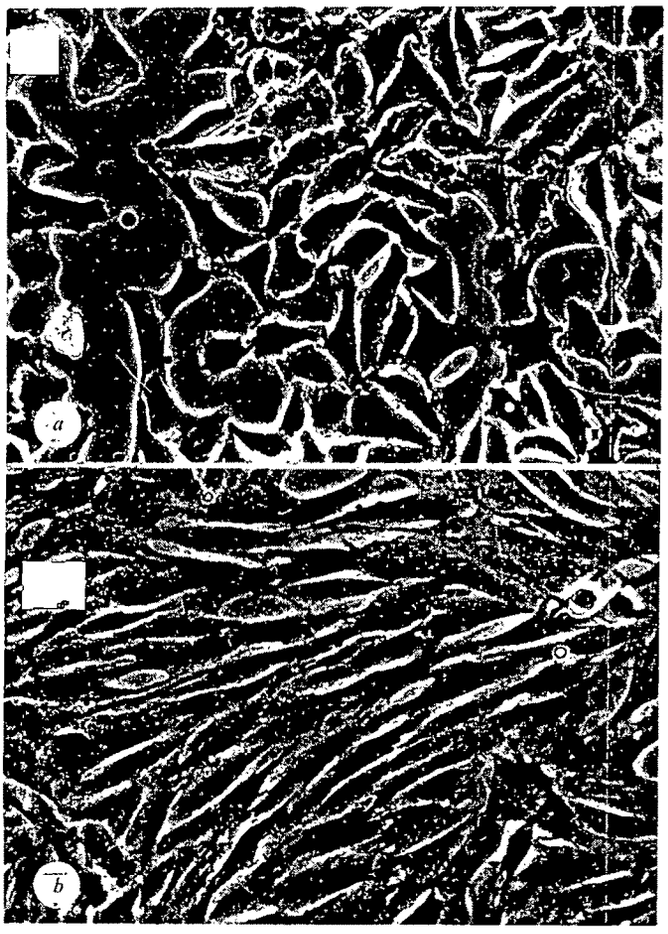

Fig. 1 Phase contrast microscopy of HBT-3 cells in cell culture. *a*, HBT-3Ep cells (×286); *b*, HBT-3 cells after prolonged cultivation with medium containing 5 μg ml^{-1} testosterone acetate (×286). Both cell types were grown at 37° C in 75 cm^2 plastic flasks (Falcon) utilising RPMI-1640 medium containing 15% v/v heat-inactivated foetal calf serum (Gibco), penicillin (100 μg ml^{-1}) and streptomycin (10 μg ml^{-1}). Weekly cell passages were made using 0.25% trypsin.

(MuMTV), the genetic susceptibility of the host and the hormonal environment[3-7]. Although murine mammary carcinoma has been studied extensively, other mammalian systems are less well characterised. Viruses with C-type morphology have been detected by EM in mammary carcinomas of the rat[8], cat[9] and rhesus monkey[10]. EM examination of human breast cancer biopsies has on occasion revealed virus-like particles[11-14], but virus has not been detected in human breast cancer cell lines[1,15-16]. The RNA-dependent DNA polymerase (RDP) assay or the more rigorous 'simultaneous detection' of 60S-70S RNA have been used to detect oncornavirus-like properties in some human milk samples[17-19]. Keydar *et al.* have found particulates with similar properties banding at a density of 1.17 g ml^{-1} in the supernatant fluids of human embryonic cells cocultivated with human breast cancer cells or treated with milk from breast cancer patients known to contain 60S-70S RNA and RDP activity[20]. RNA tumour virus expression in cell culture has been activated or enhanced by growing cells in the presence of halogenated pyrimidines, particularly iododeoxyuridine (IUdR) and bromodeoxyuridine[21-23]. McGrath[4] has shown MuMTV release concurrent with hormone-induced cellular organisation in cultured BALB/cfC$_3$H mammary tumour cells. Moreover, IUdR rescue of C-type virus from mouse fibroblasts is markedly stimulated by the presence of adrenal glucocorticosteroids[24]. We now report that a C-type RNA virus can be activated by IUdR from HBT-3 cells following a testosterone induced morphological alteration.

HBT-3 cells were obtained from Dr Robert Bassin (NCI) at passage level 28. A single clone derived from this cell culture was used for all subsequent studies. Cells grown in the presence and absence of 5 μg ml^{-1} testosterone acetate (Sigma) were observed frequently with a phase contrast microscope. After 8 weeks of continuous cultivation with testosterone, contact-inhibited spindle-shaped cells (HBT-3S) began to appear (Fig. 1*b*). Within 4 d these cells comprised 90% of the population and on subsequent passage no epithelial cells could be discerned by light microscopy. Karyotyping of the spindle-shaped cells revealed two of the original chromosome markers (personal communication from C. S. Stulberg). The lack of any significant change in cell numbers or cell doubling time indicates that the HBT-3Ep cells were morphologically changed to HBT-3S cells. If testosterone is removed within 2 weeks after this change the HBT-3S cells revert to the HBT-3Ep form, taking 2–3 weeks for reversal to occur. The change is not reversible, however, if testosterone is removed later than 2 weeks after the HBT-3S cells appear. These cells have been maintained in culture for up

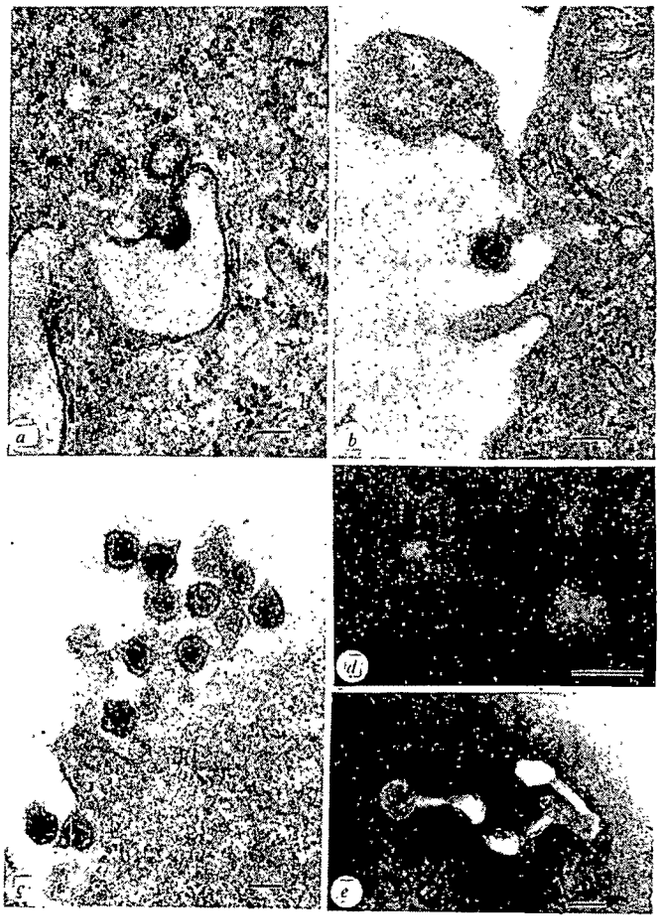

Fig. 2 Virus particles activated from HBT-3S with testosterone acetate and IUdR. *a*, C-type virus budding from cell membrane. The marker represents 100 nm. After IUdR-testosterone activation, cells were fixed in 2.5% glutaraldehyde, postfixed in 1% osmium tetroxide, dehydrated and embedded in Epon[26]. Thin sections cut on an LKB Ultratome were stained with 2% aqueous uranyl acetate and lead citrate[27] and examined with a Phillips 300 electron microscope. *b* and *c*, Extracellular C-type virus. The marker represents 100 nm. *d*, Negatively stained preparation of virus using phosphotungstic acid (PTA). Virus containing fluid collected from IUdR-testosterone-activated cells was centrifuged at 4,000 r.p.m. for 15 min and the supernatant subjected to centrifugation at 95,000*g* for 60 min. The resultant pellet was suspended in 0.5 ml of 0.05 M sodium citrate and mixed 1:3 with 2% PTA and examined by EM on formvar-carbon coated grids. The marker represents 100 nm. *e*, Negatively stained virus from 1.15 g ml^{-1} band of isopycnic sucrose density gradient (see Fig. 3*b*). The marker represents 100 nm.

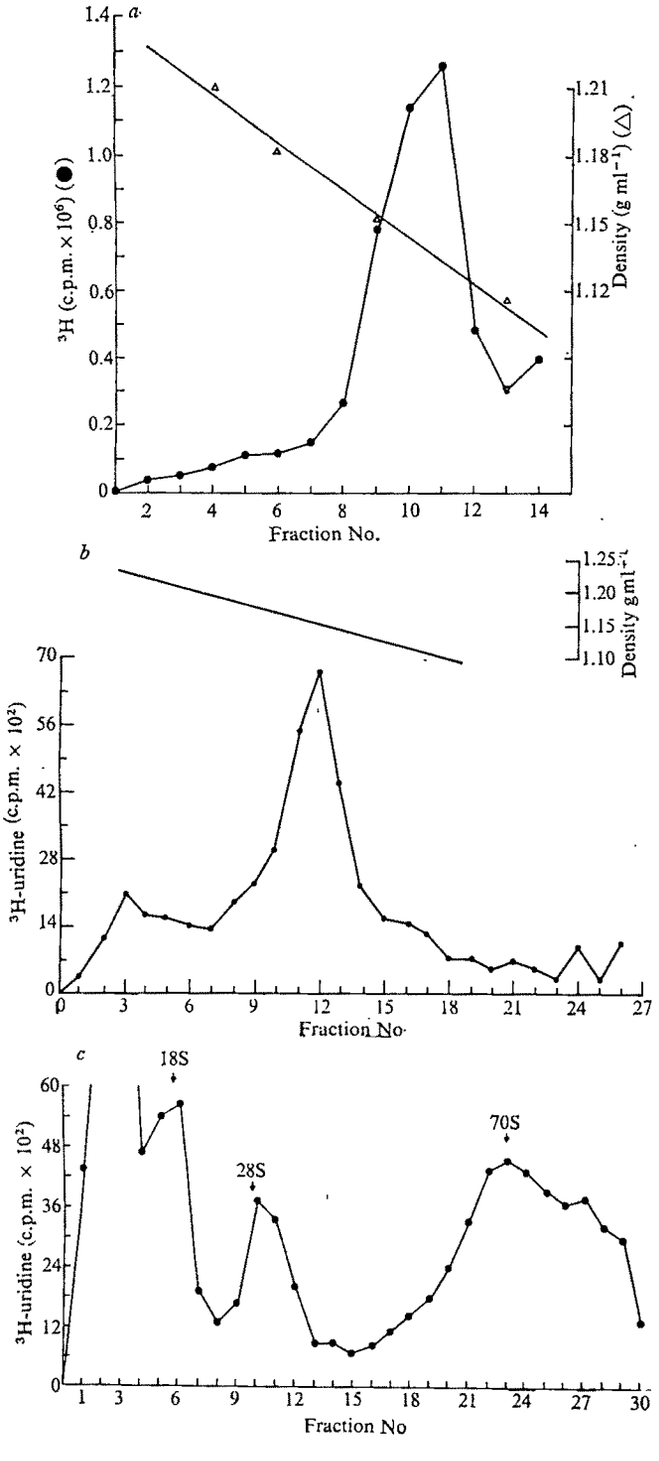

Fig. 3 RNA-dependent DNA polymerase activity and density of HBT-3S IUdR rescued virus and sedimentation rate of its associated RNA. *a*, RDP activity of virus banded in an isopycnic density gradient. IUdR-treated HBT-3S cultures were incubated for 72 h with 100 μg ml^{-1} IUdR. The collected culture fluids were clarified at 10,000*g* for 10 min. The clarified medium was then centrifuged at 80,000*g* for 60 min. The pellet from this centrifugation was resuspended in phosphate buffered saline, layered over a 10–65% linear sucrose gradient in a Beckman SW-40 rotor and centrifuged for 4 h at 200,000*g*. Sedimentation is from right to left. The indicated fractions were diluted to 5 ml with cold growth medium and centrifuged at 80,000*g* for 60 min in a Beckman No. 30 rotor. The tube was drained, 120 μl of a detergent solution was added and two 50 μl aliquots were added immediately to 50 μl reaction mixtures, with (+) and without (−) added polyriboadenylic·oligodeoxythymidylic acid (poly (rA)·poly (dT)$_{(12-18)}$) template. The final reaction in 0.1 ml contained 0.016% Nonidet P-40 (Shell Chemical Co.), 30 mM *tris*-hydroxymethylaminomethane (Tris) hydrochloride (*p*H 8.5), 50 mM dithiothreitol (DTT), 0.5 mM manganese acetate, 30mM sodium chloride, (+) 0.10 A_{260} units poly (rA)·poly (dT)$_{(12-18)}$; 1.0 μM thymidine triphosphate (TTP) methyl-^{3}H (55 Ci mmol^{-1}) and was incubated for 30 min. at 37° C. Trichloracetic acid (TCA) precipitable material was counted on membrane filters (Schleicher and Schuell) in a Packard model 3375 scintillation spectrometer. The data are corrected for (−) poly(rA)·poly(dT)$_{(12-18)}$ (< 200 c.p.m.). *b*, Isopycnic sucrose density gradient centrifugation of ^{3}H-uridine labelled virus from IUdR-activated HBT-3S cells. Conditions were as in (*a*) except that ^{3}H-uridine (50 μCi ml^{-1}) was added simultaneously during IUdR induction and 25 μl aliquots were counted. Sedimentation is from right to left. *c*, Sucrose gradient sedimentation of RNA extracted from 1.15 g ml^{-1} ^{3}H-uridine labelled virus. Fractions between 1.136 and 1.165 g ml^{-1} (from *b*, above) were pooled and diluted to 25 ml with TNE buffer (0.01 M Tris, *p*H 7.5, 0.1M NaCl, and 0.001 M EDTA). The pool was centrifuged for 60 min at 80,000*g* and the virus pellet was resuspended in 200 μl of a solution containing 0.25M Tris, *p*H 7.5, 0.05M EDTA, 2.5% sodium lauroyl sarcosinate, 6% sodium dodecyl sulphate (SDS), 2.5 mM magnesium chloride and 0.1 mM calcium chloride. An equal volume of TNE buffer-saturated phenol was added. The suspension was vortexed and 2.5 volumes of ethanol (−20° C) were added to the aqueous phase. The precipitate was solubilised in 400 μl of TNE buffer (0.1% SDS) and sedimented through a linear sucrose gradient (10–30% w/v sucrose in TNE plus 0.1% SDS) for 3.5 h at 200,000*g* in a Beckman SW-40 rotor. Sedimentation is from left to right. Each fraction was combined with 100 μg yeast carrier RNA, precipitated onto TCA filters and counted as above.

to 3 months. In repeated EM examination no virus was detected in either thin section of cells or in negatively stained preparations of cell-free supernatants in the HBT-3Ep or the HBT-3S cells. Moreover, no significant levels of RDP were detected in the cell-free supernatant of either cell type (Table 1). To determine whether virus expression in either cell type could be induced by IUdR, HBT-3Ep and HBT-3S cells were exposed for 3 d to medium containing IUdR (P-L Biochemicals) at a concentration of 100 μg ml^{-1} (ref. 25). After IUdR treatment only the HBT-3S cells produced C-type virus detectable by both RDP assay (Table 1) and EM (Fig. 2).

The virus is typically 85–100 nm in external diameter with a 40–58 nm core (Fig. 2). It is found extracellularly and budding from the cell membrane in a characteristic C-type formation (Fig. 2*a*, *b* and *c*). It does not resemble MuMTV[3] which has A and B-type particles or the Mason–Pfizer monkey virus (MPMV)[10] which buds as a B-type virus. Phosphotungstic acid (PTA) negatively stained preparations reveal tailed C-type particles without surface spikes with occasional blebs on the tails (Fig. 2*d* and *e*).

Table 1 RNA-dependent DNA polymerase activity of HBT-3Ep and HBT-3S cells treated with IUdR and testosterone

	HBT-3Ep	HBT-3S*
Control	96	152
IUdR†	120	18,190

RDP activity is expressed in c.p.m. For details of assay see legend to Fig. 3*a*.
*HBT-3S cells were derived from HBT-3Ep cells by testosterone as described in the text. Testosterone was maintained in the culture medium for 6 weeks after the appearance of the HBT-3S cells at which time they were used in this study.
†Iododeoxyuridine, 100 μg m^{-1} of medium for 3 d.

RDP analysis of supernatants of the IUdR-induced HBT-3S cells banded in sucrose reveals a single peak of maximum activity at a density of 1.13 to 1.15 g ml^{-1} (Fig. 3*a*). When HBT-3S cells are isotopically labelled with ^{3}H-uridine during IUdR induction, a band of labelled virus is obtained at a density of 1.15 g ml^{-1} (Figs. 2*e* and 3*b*). RNA extracted from this band by the phenol method and sedimented on a sucrose gradient reveals both 70S and 28-30S ^{3}H-uridine labelled regions unique to C-type viruses (Fig. 3*c*). Thus, the biochemical and morphological characterisation identify this as a C-type virus.

Preliminary immunological evaluation of the virus by means of indirect immunofluorescence studies of the IUdR-treated cells reveals a lack of activity with antisera to rat (R-35), murine (Rauscher), feline (feline leukaemia and RD114) and primate (woolly monkey, MPMV, and gibbon ape) viruses. Repeated attempts to cultivate this virus in human and other mammalian cells have not been successful nor does this virus have an observable effect on HBT-3Ep or HBT-3S cells. Intraperitoneal and subcutaneous inoculations of BALB/c mice with 10^7 virus particles have not revealed pathological characteristics for up to 4 months after inoculation.

The requirement for testosterone as a prerequisite to viral activation suggests that it, together with IUdR, has a derepressing function on the viral genetic information within HBT-3S cells. However, demonstration of antigenic determinants and nucleic acid homology to human cancer cells remain to be completed before any definitive statement regarding virus origin can be made. Moreover, the role of this virus, if any, in the aetiology of human cancer remains to be fully elucidated.

We thank Drs Robert Bassin, C. S. Stulberg, Angelo Andrese, and Robert Manaker for advice, Miss Mary Jane Madden for technical assistance and Mr Donald Stoderl for photography.

Note added in proof: The presence of chromosomes in HBT-3 cells characteristic of HeLa has been reported[28]. Although the origin of the HBT-3 cells is uncertain, we have established that testosterone and iododeoxyuridine may be used to activate a C-type virus from them and may be a useful technique for virus activation in other cell systems.

Hepatitis B-specific DNA polymerase activity during post-transfusion hepatitis

HEPATITIS B antigen (HBAg, Australia antigen) has been associated definitively with long incubation human hepatitis[1–4]. It appears before the onset of acute illness[3,4] and decreases during convalescence, with the concomitant development of anti-HBAg[5]. In addition to this classical course of the disease, the discovery of HBAg has revealed subclinical infections, as demonstrated by seroconversion to HBAg (ref. 6), and the carrier state, where antigen is present in blood for long periods with either chronic hepatitis or no apparent disease[7]. Levels of HBAg in blood seem unrelated to the severity of disease, for carriers who generally have high titres of circulating antigen, in most cases, show slight if any liver damage[8,9].

Several structures found in plasma carry HBAg determinants[10–14] including 43 nm spherical particles with 27 nm electron dense cores first described by Dane *et al.*[14]. DNA polymerase activity is associated with the core of a subpopulation of Dane particles in apparently normal carriers[15]. We have now found polymerase-containing particles in blood during acute infection.

We collected serial plasma samples from multiply transfused patients at frequent intervals after surgery, and analysed them for HBAg by a solid phase radioimmunoassay[16], for anti-HBAg by passive haemagglutination[17] and for serum glutamic-pyruvic transaminase (SGPT)[18]. Some samples had been stored at −20° C for up to 3 yr.

Undiluted plasma (25 μl) was used to detect DNA polymerase activity by the procedures described before[15]. When polymerase activity was detected, we investigated whether it was HBAg-specific. Test samples (50 μl) were mixed with 15 μl of either guinea pig anti-HBAg (*ay*) (NIAID Research Resource Reagent V802–501–558) or normal guinea pig serum, and incubated at 37° C for 60 min. Rabbit anti-guinea pig IgG (50 μl) was then added and followed by incubation at 37° C for a further 60 min. The preparation was then centrifuged at 1,300*g* for 15 min and 50 μl of supernatant was removed and assayed for polymerase activity. Polymerase was considered to be specific if antiserum directed against HBAg removed activity from the supernatant while normal serum had no effect.

In the first experiment coded specimens from three patients were tested for the presence of DNA polymerase activity. In a patient who received nineteen 500 ml units of whole blood during open-heart surgery (one of which was positive for HBAg by radioimmunoassay but negative by counterimmu-

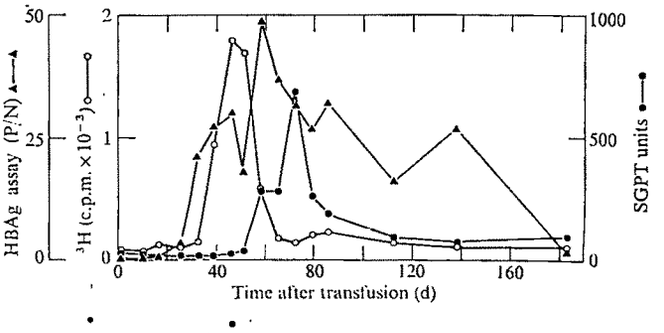

Fig. 1 A case of post-transfusion HBAg-positive hepatitis. Serial plasma samples were tested for HBAg-specific DNA polymerase. (○); HBAg by radioimmunoassay (▲); and SGPT levels (●).

noelectrophoresis) and who subsequently developed post-transfusion type B hepatitis, the first sign of infection was detection of HBAg at day 25 (Fig. 1). Fourteen days later DNA polymerase activity could be detected in unconcentrated serum. Using ten-fold concentrates prepared as described before[10], DNA polymerase could be detected 7 d after the appearance of HBAg (day 32). Polymerase activity reached a peak on day 46, after which it decreased rapidly. The level of HBAg-specific polymerase was low when the peak titre of HBAg was observed (day 58), and was no longer detectable when the peak SGPT was reached (day 72).

Figure 2*A* shows the pattern observed with a patient who received HBAg-negative blood units and appeared normal throughout the study. Serum transaminase levels in this patient were never increased and no HBAg was demonstrated by radioimmunoassay. DNA polymerase activity was not detected in serial samples obtained during the 6 months following transfusion. Figure 2*B* shows the pattern for a patient who developed post-transfusion HBAg-negative hepatitis. Transaminase levels were normal until day 37, when they increased, reaching a maximum of 1,200 on day 44. Throughout the disease no serial samples had detectable DNA polymerase activity.

Table 1 Presence of HBAg-specific polymerase in multiply transfused surgical patients

Group	SGPT*	HBAg†	No. positive‡/No. tested
1	+	+	7/9
2	+	0	0/1
3	0	0	0/4

* Increased to >100 U ml^{-1}.
† Greater than 2.1 times the mean of negative controls by a solid phase radioimmunoassay.
‡ Tested for specificity by immunoprecipitation.

Serial samples from a number of multiply transfused patients were tested under code for polymerase activity and the results obtained, as well as those for the three cases previously described, are summarised in Table 1. Seven of the nine patients who developed post-transfusion hepatitis B as indicated by the presence of HBAg and elevated SGPT (group 1) had detectable HBAg-specific DNA polymerase activity in their plasma during acute infection. In all cases this preceded signs of liver damage as measured by elevated SGPT levels, and appeared slightly after HBAg was first detected. Polymerase activity was not found in the plasma of a patient with HBAg-negative post-transfusion hepatitis (group 2, Fig. 2*B*) nor in four control individuals (group 3). No individual in groups 2 and 3 developed antibody against HBAg. One of the four controls showed polymerase activity, however this activity could not be precipitated with specific antibody and was therefore not considered positive. One of the two individuals with HBAg-positive post-transfusion hepatitis who was considered negative for DNA polymerase also showed this non-specific polymerase activity.

These results show that in most cases HBAg-specific DNA polymerase activity can be detected in plasma from acutely infected individuals. Peak levels of activity detected were higher than those found in the plasma of most carriers (unpublished results). The transient nature of enzyme-containing Dane particles in the blood, and the time at which the peak activity was found resembles the viraemias associated with other viral diseases[19,20]. These data support the hypothesis that the Dane particle is the virus of hepatitis B.

Virus-induced liver damage was not responsible for the presence of the DNA polymerase activity for several reasons. First, activity appeared before liver damage; second, in post-transfusion HBAg-negative hepatitis, where levels of SGPT were increased (Fig 2*B*), no polymerase activity was detected; and third, the enzymatic activity was associated with an antigenic particle, for highly specific anti-HBAg

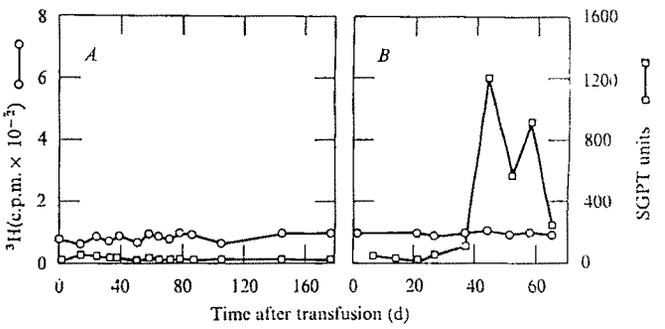

Fig. 2 Two multiply transfused surgical patients, one who showed no clinical disease and was HBAg-negative throughout the course of the study (*A*), and one who developed post-transfusion HBAg-negative hepatitis (*B*). Serial plasma samples were tested for DNA polymerase activity (○) and SGPT levels (□).

precipitated the activity.

Clearly, the radioimmunoassay detects HBAg before the demonstration of DNA polymerase activity, but it detects all antigenic structures in plasma while DNA polymerase activity is much more restricted and is probably only a measure of the presence of circulating Dane particles. If the Dane particle is the virus of hepatitis B, then the actual titre of infectious virus in an HBAg-positive serum may correlate better with the level of specific DNA polymerase than with the titre of HBAg.

We thank Dr Andrew G. Morrow for sera from his patients. The Rockville Laboratory of the MAN Program is supported by the National Institute of Allergy and Infectious Diseases under Union Carbide's contract with the US Atomic Energy Commission.

Detergent-solubilised H-2 alloantigen is associated with a small molecular weight polypeptide

THERE have been several reports that purified papain-solubilised HL-A alloantigens contains two polypeptides with molecular weights of approximately 31,000 and 11,500 (refs 1-3). The combined molecular weights of these two polypeptides (42,500) is similar to the molecular weight reported for detergent-solubilised HL-A alloantigens (43,000) (ref. 4). The smaller fragment seems to resemble β_2 microglobulin[3,5], which has an amino acid sequence homologous to that of an immunoglobulin heavy chain constant region domain[6]. This smaller fragment does not seem to contain any alloantigenic activity[5] and is found in association with several different HL-A alloantigenic molecules[1,3]. Further evidence of the close association of these two polypeptides is based on observations that capping or immunoprecipitation of β_2 microglobulin using antisera directed against β_2 microglobulin results in the cocapping[7] or coprecipitation[8] of HL-A molecules. One critical question is whether the HL-A alloantigens and β_2 microglobulin are covalently[5] or noncovalently joined to one another. Our studies on a homologous system, the H-2 complex of the mouse, suggest that mouse H-2 alloantigens are noncovalently associated with a small polypeptide.

We report here that detergent-solubilised H-2 alloantigens from the mouse, purified by immunoprecipitation, contain two polypeptides with molecular weights of 47,000 and 11,500. Since the smaller polypeptide has a molecular weight comparable with that of the β_2 microglobulin molecule associated with HL-A alloantigens, it seems likely that it represents the murine equivalent of β_2 microglobulin. Also, since our solubilisation and purification procedure does not include any known proteolytic action, we propose that the small polypeptide does not represent a covalently-linked component of the H-2 alloantigen, but rather represents a molecule which for unknown reasons has a strong affinity for the major histocompatibility antigen of mice.

Proteins of B10.D2 spleen lymphocytes were labelled with either ^{125}I according to Marchalonis *et al.*[9], or by culturing spleen lymphocytes in Hanks balanced salt solution (Gibco) in the presence of ^{3}H-amino acids for 4–8 h. Briefly, radioiodination was performed by suspending 5×10^7 spleen lymphocytes in 0.5 ml of a phosphate buffered saline (PBS) solution at pH 7.4 which contained 100 μg lactoperoxidase and 5 mCi ^{125}I. Hydrogen peroxide (50 μl of 0.03% solution in PBS) was added and the suspension was incubated for 5 min at room temperature. This was followed by washing of the cells in PBS. Lactoperoxidase-catalysed radioiodination labels cell surface proteins only[9] whereas the short culturing procedure using ^{3}H-amino acids labels all proteins with a rapid turnover rate. Membranes of labelled cells were solubilised by incubation with 0.5% Triton X-100 (Sigma) in a mixture of 0.01 M Tris buffer, pH 7.4 and 0.15 M NaCl for 20 min at 0° C. Labelled immunoglobulin was preprecipitated by the addition of normal mouse serum and rabbit anti-mouse immunoglobulin. H-2 alloantigenic activity was immunoprecipitated as described in Fig. 1. Sodium dodecyl sulphate (SDS) acrylamide gel electrophoresis of the immunoprecipitate of H-2.4 alloantigenic activity in the presence of reducing agent revealed two polypeptide chains with molecular weights of 47,000 and 11,500 respectively, and a third peak of radioactivity which moved with the front, was dialysable, and was present in both the specific and nonspecific immunoprecipitates to the same extent (Fig. 1*a*). When a ^{3}H-amino acid-labelled antigen preparation was used, immunoprecipitates yielded only two radioactive peaks coincident with the ^{125}I-polypeptides (Fig. 1*b*).

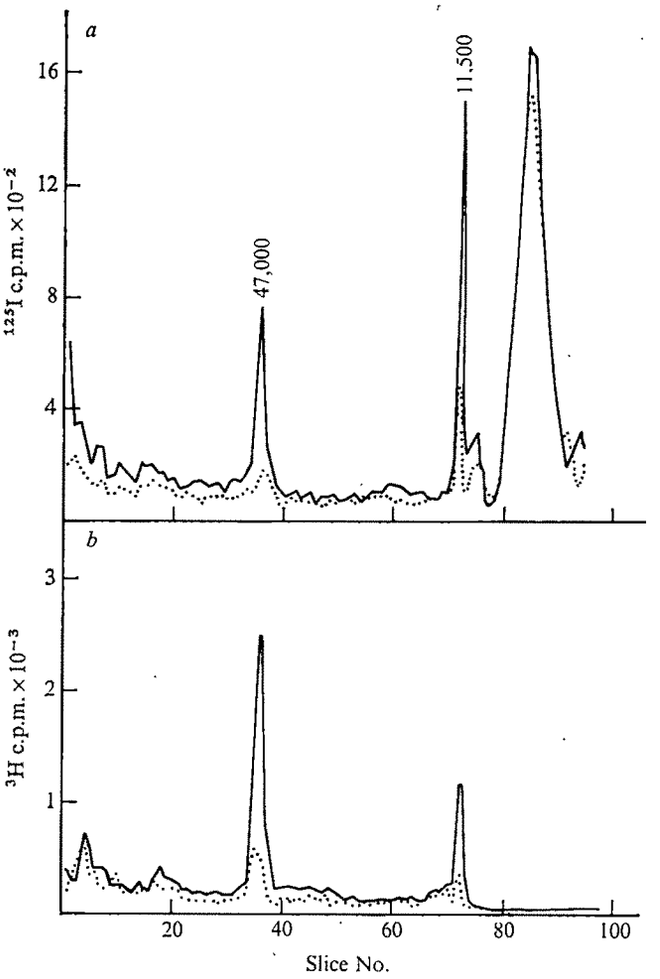

Fig. 1 Antigen preparations labelled with either ^{125}I (*a*) or ^{3}H (*b*) from which labelled immunoglobulins had been removed by preprecipitation were treated with either 4 μl of D-4 H-2 alloantiserum and 16 μl of C57BL/10 normal mouse serum (—) or 20 μl of C57BL/10 normal mouse serum (...). H-2 alloantiserum D-4, which was obtained from the National Institutes of Health, was made in the strain combination (B10. AKM × 129) F_1 anti-B10.A, and is therefore directed against the H-2.4 antigenic specificity of the H-2D region of the H-2^a haplotype. After incubation for 30 min at 0° C, 100 μl of rabbit anti-mouse immunoglobulin was added and incubated at 0° C for 150 min. The resultant precipitate was washed three times, dissolved in 100 μl of Laemmli reducing buffer[10], and electrophoresed on 10% polyacrylamide SDS gels according to Laemmli[10]. Gels were cut into 1 mm thick slices and counted in either a gamma counter (^{125}I) or a liquid scintillation counter (^{3}H). Molecular weights of the major peaks are indicated.

It should be noted that when normal mouse serum was used as a control in the immunoprecipitation method, small radioactive peaks were observed coincident with and in the same relative ratio as those observed using specific anti-H-2 serum. We believe that this is due to a small degree of reactivity of the small polypeptide (presumably the mouse analogue of β_2 microglobulin) with rabbit anti-mouse im-

munoglobulin, and that partial precipitation of this polypeptide by this reagent also results in partial coprecipitation of the H-2 alloantigenic molecule which is associated with it. SDS polyacrylamide gel electrophoresis of immunoprecipitates in the absence of reducing agent also revealed the smaller polypeptide peak, indicating that it was not bound by disulphide bonds to the larger polypeptide.

Our data indicate that the smaller polypeptide present in our immunoprecipitates is strongly associated with H-2 alloantigens, is present on the surface of lymphocytes, is rapidly synthesised, and has a molecular weight of 11,500. All of these properties are consistent with those of the β_2 microglobulin-like molecule associated with papain-solubilised HL-A alloantigens. Sequence analysis of the smaller polypeptide molecule is in progress in our laboratory to determine whether it is indeed the murine analogue of β_2 microglobulin. We feel that further speculation concerning the role of β_2 microglobulin as a component of HL-A alloantigens will require detailed chemical analyses of detergent-solubilised alloantigens.

Our investigations reveal that H-2 alloantigens are closely although noncovalently associated with a smaller polypeptide molecule. The strong affinity which these two membrane proteins exhibit for each other suggests that they may function as complementary receptors on the surfaces of lymphocytes and, accordingly, play a part in cellular recognition and(or) interactions.

Demonstration of acetylcholine-sensitive adenyl cyclase in malignant neuroblastoma cells in culture

WE have recently reported[1] the existence of dopamine-sensitive adenyl cyclase (AC) in mouse adrenergic neuroblastoma cells which contain tyrosine hydroxylase (TH) but no choline acetyltransferase (ChA); whereas, noradrenaline-sensitive AC at low noradrenaline concentrations becomes apparent in cyclic AMP induced 'differentiated' neuroblastoma cells. The presence of acetylcholine receptors in neuroblastoma cells has been demonstrated by Harris and Dennis[2]. These acetylcholine receptors are blocked by nicotinic and muscarinic inhibitors[3]. We now report the presence of acetylcholine-sensitive AC in addition to dopamine- and noradrenaline-sensitive AC in inactive neuroblastoma cells which contain neither TH nor ChA, and in cholinergic neuroblastoma cells which contain ChA but no TH. Acetylcholine, dopamine and noradrenaline produced an additive stimulatory effect on AC activity, suggesting that these neurotransmitters act on different receptor sites all of which are linked with AC.

The procedures for culturing and maintaining the mouse neuroblastoma cells were previously described[4]. Cells of previously defined[5] clones NBDB$^-$ and NBE^-_A were used. The effects of dopamine, noradrenaline and acetylcholine on the AC activity in homogenates of malignant neuroblastoma cells were measured. Cells (0.5×10^6) were plated in large Falcon plastic flasks (75 cm^2). The medium was changed first at day 2 and then every day thereafter. The samples for enzyme assay were prepared 4 d after plating. The cells were washed twice with phosphate buffer solution (*p*H 7.0), 5 ml of Tris-HCl (*p*H 7.5, 0.05 M) was added to each flask, and then the cells were removed from the flask surface using a Pasteur pipette. The contents of four flasks were pooled, and then the cells were frozen, thawed and homogenised. It is essential that cells are gently homogenised immediately after thawing as a longer interval between thawing and homogenisation decreases the enzyme activity. In addition, the stability of AC under frozen conditions varies from one clone to another. The stability of AC activity in frozen adrenergic cells could be maintained for more than a week; however, in cholinergic cells enzyme activity decreases by about 40% within a week. Therefore, the AC activity was assayed in samples which were frozen for a maximum of 3 d. The AC activity was determined by a modification[6] of the procedure described by Krishna *et al.*[7] Essentially, the formation of ^{3}H-cyclic AMP from ^{3}H-ATP is measured. The assay system was modified to include phosphoenolpyruvate and pyruvate kinase to recycle ADP formed by ATPase activity back to ATP. Also, cyclic AMP (0.8 mM) was included in the assay as a trap for the ^{3}H-cyclic AMP formed during the incuba-

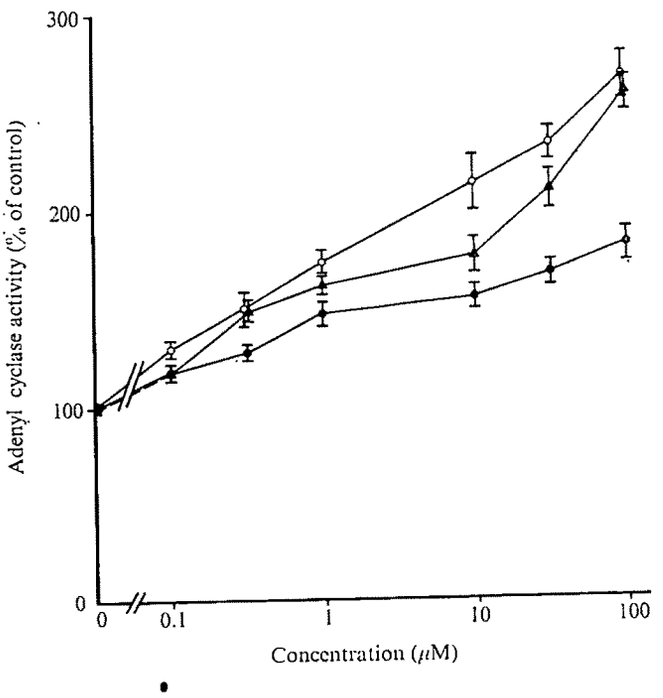

Fig. 1 Changes in adenyl cyclase activity (AC) in homogenates of inactive neuroblastoma cells. The basal activity of AC (22±2 pmol per mg protein per min) was considered 100% control values and the AC values of treated cells were expressed as percent of control. Each value represents an average of four to six samples. The bar at each point is standard deviation. Treatment with: ○, dopamine; ▲, acetylcholine; ●, noradrenaline.

tion. The incubation period for each sample was 15 min. The absorbance at 260 nm of the purified cyclic AMP fraction serves as a measure of recovery of ^{3}H-cyclic AMP. The formation ^{3}H-cyclic AMP was linear with time up to 30 min at 37° C and linear with protein concentration over the range 0.05–1.0 mg ml^{-1}. The total volume of the incubation mixture was 1.0 ml. The protein was determined by the method of Lowry *et al.*[8]. Data were expressed as pmol cyclicAMP formed per mg protein per min.

The procedures for making solutions of dopamine, noradrenaline and prostaglandin (PG)E$_1$ were previously described[1]. To study the nature of receptors, propranolol (blocks β-receptors), phentolamine (blocks α-receptors), haloperidol (blocks dopamine-receptors), atropine (blocks acetylcholine-muscarinic receptors), hexamethonium and nicotine (blocks acetylcholine-nicotinic-receptors) were used. These agents were dissolved in 0.01 N HCl. Nicotine was dissolved in 70% ethyl alcohol. In addition, analogues of acetylcholine such as bethanechol and carbachol were used, since they are virtually resistant to acetylcholinesterase or non-specific cholinesterase. Carbachol stimulates both muscarinic and nicotinic receptors, whereas bethanechol has primarily nicotinic activity.

Figure 1 shows that low concentrations of acetylcholine, dopamine and noradrenaline stimulated AC activity in homogenates of inactive neuroblastoma cells. Noradrenaline was much less active than either dopamine or acetylcholine. A maximal stimulation of AC activity was achieved by 100 μM of any of these neurotransmitters; however, noradrenaline produced only 80% stimulation, whereas acetylcholine and dopamine produced about 160% stimulation in AC activity. None of the above neurotransmitters at a higher concentration (1,000 μM) produced any significant effect on the basal activity of AC.

Acetylcholine (100 μM) also stimulated AC activity in the cholinergic neuroblastoma cells to about the same extent as that produced in the inactive neuroblastoma cells (data not shown).

Table 1 shows that PGE$_1$ and serotonin also stimulated AC activity; however, adrenaline and histamine had no significant effect. Bethanechol and carbachol also stimulated AC activity, but less than did acetylcholine. The reasons for acetylcholine being more effective than bethanechol and carbachol are not known. When these agents were combined individually with acetylcholine, they produced an additive stimulatory effect on AC activity. The combination acetylcholine with dopamine or noradrenaline or both produced an additive stimulatory effect on AC activity, indicating that these agents act on the different receptors. Acetylcholine-stimulated AC activity was markedly reduced by atropine, nicotine, and hexamethonium; but it was not significantly affected by haloperidol, phentolamine and propranolol (Fig. 2). Dopamine and noradrenaline stimulated AC activity was markedly inhibited by 10 μM of haloperidol and propranolol, respectively (data not shown). Atropine also reduced dopamine-stimulated AC activity; however, it reduced noradrenaline-stimulated AC activity only slightly (Fig. 3). Atropine, hexamethonium, nicotine, haloperidol, propranolol or phentolamine alone produced no significant effect on the basal activity of AC.

Table 1 Effect of combination of various neurotransmitters on adenyl cyclase activity in homogenates of neuroblastoma cells (NBDB$^-$)

Treatment	Adenyl cyclase activity (pmol per mg protein per min)
Control	22 ± 2*
Dopamine (100 μM)	58 ± 3
Noradrenaline (100 μM)	40 ± 1
Adrenaline (100 μM)	26 ± 2
Acetylcholine (100 μM)	57 ± 4
Bethanechol (100 μM)	36 ± 2
Carbachol (100 μM)	31 ± 2
Acetylcholine + bethanechol	88 ± 3
Acetylcholine + carbachol	77 ± 2
Dopamine + acetylcholine	100 ± 2
Noradrenaline + acetylcholine	92 ± 5
Dopamine + noradrenaline + acetylcholine	133 ± 3
Serotonin (100μM)	24 ± 2
Histamine (100μM)	24 ± 2
Prostaglandin E$_1$ (10 μM)	52 ± 3

*Standard deviation.
Change in adenyl cyclase activity after treatment with various neurotransmitters in homogenates of inactive neuroblastoma cells. Each value represents an average of four to six samples.

The reason for the marked reduction in dopamine-stimulated AC activity by atropine is unknown. Many blocking agents do not seem to be as specific as they have been presumed to be. For example, AC activity of neuroblastoma cells (unpublished observation) and of caudate nucleus[9] is blocked by chloropramazine in a non-specific way. Haloperidol which is supposed to be specific inhibitor for dopamine-receptors also prevents noradrenaline-stimulated cyclic AMP level in rat brain slices[10].

The fact that the muscarinic and nicotinic inhibitors of acetylcholine-receptors block acetylcholine-stimulated AC activity indicates that AC may be linked with both types of receptors. It has been suggested[11] that nicotinic receptors are linked with AC, whereas muscarinic receptors are linked with guanyl cyclase. This concept does not appear to be applicable to this neuroblastoma clone.

Since dopamine and noradrenaline do not increase the cyclic AMP level until the phosphodiesterase activity is inhibited[12], these neurotransmitters may not mimic the effect of cyclic AMP in causing differentiation of neuroblastoma cells. Indeed, when the cells were exposed to dopamine and noradrenaline for 1 h, no differentiation occurred[13], although dopamine induced reversible inhibition of cell division. A long drug-exposure was not feasible because these agents are auto-oxidised in solution. Acetylcholine (100 μM) did not produce any significant change on growth or differentiation (data not shown).

Our results demonstrate the presence of acetylcholine-sensitive AC in addition to dopamine- and noradrenaline-sensitive AC in inactive and cholinergic neuroblastoma cells. These cells thus differ from adrenergic cells in which acetylcholine-sensitive AC activity is not demonstrable and noradrenaline-sensitive AC activity does not become

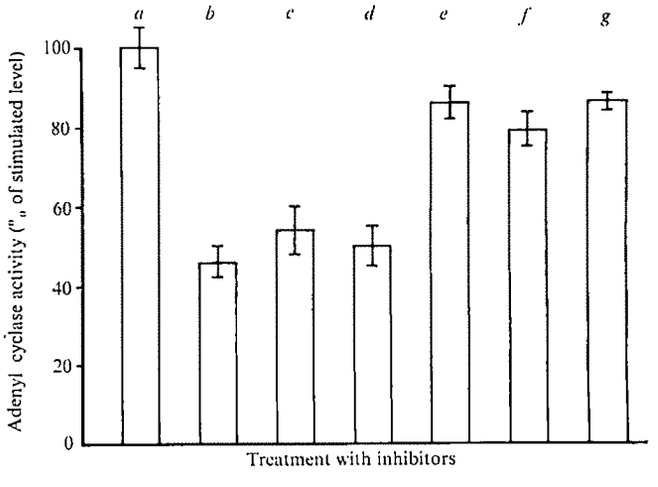

Fig. 2 Effect of various inhibitors of receptors on acetylcholine-stimulated adenyl cyclase activity in homogenates of inactive neuroblastoma cells. A concentration of 30 μM of *b*, atropine; *c*, hexamethonium; *d*, nicotine; *e*, haloperidol; *f*, phentolamine or *g*, propranolol was added immediately before the addition of ACh (100 μM). *a*, The acetylcholine-stimulated activity of adenyl cyclase (57±4 pmol per mg protein per min) was considered as 100%, and the values of AC in the presence of inhibitors were expressed as a percentage of the stimulated value. Each value represents an average of four to six samples. The bar at each point is standard deviation.

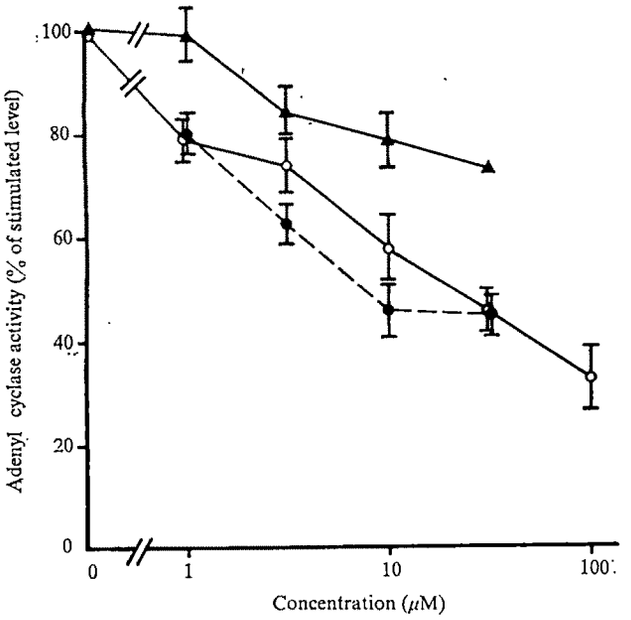

Fig. 3 Effect of atropine on acetylcholine (○)-, dopamine (●)- and noradrenaline (▲)-stimulated activity of adenyl cyclase (AC) in homogenates of inactive neuroblastoma cells. Atropine was added at various concentrations immediately before the addition of acetylcholine (100 μM) dopamine (100 μM) or noradrenaline (100 μM). The stimulated value of AC for dopamine (58±3 pmol per mg protein per min), for acetylcholine (57±4 pmol per mg protein per min) and for noradrenaline (40±1 pmol per mg protein per min) was used as 100%, and the values of AC activities in atropine-treated homogenates were expressed as a percentage of the stimulated value. Each value represents an average of four to six samples. The bar at each point is standard deviation.

apparent until the cells are differentiated as a result of raised cyclic AMP levels[4,12,14,15]. It is interesting that the application of dibutyryl cyclic AMP or acetylcholine into the lateral hypothalamic area of rat greatly increased water intake[16]. Atropine completely inhibited food and water intake induced by dibutyryl cyclic AMP[16].

The fact that the adenyl cyclase retains its sensitivity to low concentrations of acetylcholine and dopamine in homogenates of neuroblastoma cells suggests that this system may provide a sensitive method in search of new agents that can mimic or antagonise the effect of catecholamines and acetylcholine on mammalian neurones.

Effect of cyclic AMP, caffeine and theophylline on differentiation of lens epithelial cells

Papaconstantinou has clearly shown that differentiation of lens epithelial cells into fibre cells involves a complex series of morphological and biochemical events[1]; however, at the molecular level the factors involved in the initiation of this differentiation are almost entirely unknown. The purification and characterisation of the mRNA species specifying bovine lens proteins[2] have made desirable the development of a system in which details of lens differentiation could be studied. Such a system for the study of lens epithelial cell differentiation in tissue culture should have the following characteristics: (1) The differentiation should demonstrate characteristic morphological changes which can be correlated with those expected of the process *in vivo;* (2) specific proteins characteristic of the differentiated tissue should be absent in epithelial cells inoculated into the culture and should appear during the course of the morphological changes; (3) it should be possible to maintain the epithelial cells in culture in an undifferentiated state by the criteria of unaltered morphology and the absence of specific proteins), and to induce them to differentiate in response to a specific set of conditions; (4) clones of epithelial cells should show characteristics similar to freshly explanted epithelial cells. In addition to these criteria, a useful characteristic of the system would be an accelerated or inhibited differentiation in response to hormones of cyclic nucleotides.

In establishing such a system, both the choice of protein to be monitored as an indication of differentiation and the tissue to be cultured may be critical. We observed in a previous study[3] by immunofluorescent staining that epithelial cells at early stages of lens development in the rat do not contain γ-crystallins. In recent (unpublished) work we have found that when epithelial cells from embryonic or newborn rat lenses are cultured, no γ-crystallins can be found initially when fixed monolayer cultures of freshly explanted epithelial cells are stained by indirect immunofluorescence, but that subsequently such cells grow and differentiate morphologically, and in 5 d may be stained positively for γ-crystallins.

One of the most marked features of the monolayer cultures is the stimulation of cell growth and acceleration of the appearance of the γ-crystallins by dibutyryl cyclic AMP. At 24 h, in contrast to controls (Fig. 1*a*), monolayers treated with dibutyryl cyclic AMP (Fig. 1*b*) or caffeine (over the concentration range 10^{-6} to 10^{-3} M) exhibited patches of confluent growth and all the single cells were elongated in patterns similar to those observed for control cells only after three

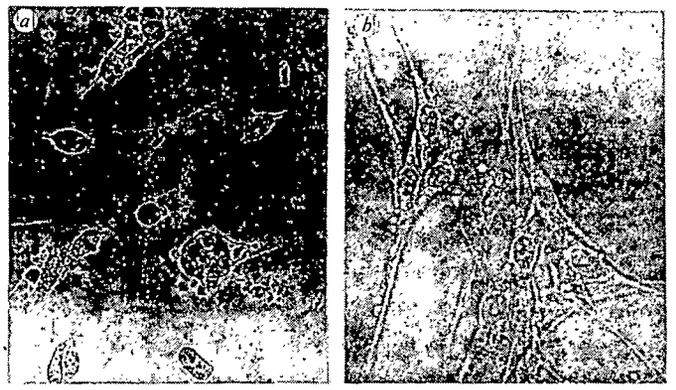

Fig. 1 Lens epithelial cells were removed from 1-d-old rat lens by 30 min treatment in medium 199 containing 0.08% trypsin at 37° C. A suspension culture of medium washed cells were incubated at 37° C in screw-capped shaker culture flasks. The cells were grown in suspension culture medium 199 containing 20% foetal calf serum, 0.1% D-L glutamine, penicillin G-sodium 100 U ml^{-1} and dihydrostreptomycin sulphate 100 μg ml^{-1}. The *p*H was adjusted to 7.1 with sodium bicarbonate. After 5 d growth cells were inoculated in fresh medium into tissue culture chamber slides (Lab-Tek) at a density of 3.3×10^8 ml^{-1}. This high cell concentration was necessary since only 10–12% of the cells will attach to the glass. After 6 h the unattached cells were removed by sterile aspiration of the media and fresh media added. Monolayer cultures were incubated at 37° C, 100% humidity in an atmosphere of 5% CO_2–95% air. Medium (0.8 ml per chamber) was changed after 2 d and subsequently every 2 d. All test substances were present from the time of monolayer inoculation. Phase contrast micrographs were taken under white light 24 h after inoculation (×370.50). *a*, Normal cultures of lens epithelial cells; *b*, culture treated with dibutyryl cyclic AMP (1×10^{-5} M).

days of growth. After 48 h in such treated monolayers strong γ-crystallin immunofluorescence was detected. No cell elongation or areas of confluent growth were found in monolayers incubated with butyric acid, cyclic GMP or theophylline (also over the concentration range 10^{-6} to 10^{-3} M), but caffeine potentiated the effect of cyclic AMP.

This effect is in marked contrast to the usual inhibitory effect of high concentrations of cyclic AMP on the growth of a number of cell lines[4–8], and on the differentiation of an established myogenic cell line[4]. It occurs at much lower concentrations of cyclic nucleotide than used to stimulate differentiation of the mouse neuroblastoma cell line (5 mM) (ref. 9), or the temporary stellate configuration in adult newt iris cells[10]. It is likely that a growth response to cyclic nucleotides is typical of embryonic or neonatal cells[11], but the additional possibility of inducing differentiation in rat lens epithelial cells is expected to be valuable in exploring differentiation at the molecular level.

New unstable haemoglobin (Hb Moscva, β24 (B4) Gly→Asp) found in the USSR

THE unstable haemoglobins form a well-characterised group of human mutants which have been observed in many parts of the world[1]. We have recently cooperated in the study of two such haemoglobins seen in Moscow. Haematological and clinical aspects have been published in Russia[2,3]. One of the haemoglobins, discovered in a mildly anaemic patient who had pancreatitis (and in his son), was found to be Hb Tacoma (β30 (B12) Arg → Ser), previously described in three members of a United States Caucasian family[4]. As this haemoglobin has already been fully characterised[5] it will not be discussed further here.

The second is a new variant, Hb Moscva, with the amino acid substitution β24 (B6) Gly → Asp. It was found in a patient who suffered from myeloid leukaemia and who has since died, but it was possible to send her blood to Cambridge for further study. Incubation of the blood with brilliant cresyl blue[6] resulted in the appearance of numerous Heinz bodies. The heat instability test[7] and incubation with isopropanol[8] both caused the formation of a red precipitate confirming the presence of an unstable haemoglobin. Subsequently an unstable haemoglobin was also found in the patient's half sister (by the maternal line), and the sister's son.

Hb Moscva migrated more rapidly towards the anode than Hb A on starch gel electrophoresis at *p*H 8.6 (ref. 9) and could be removed from the haemolysate, before electrophoresis, by heat precipitation[7]. There was only a single Hb A_2 fraction indicating that the abnormality was probably in the β, rather than the α chains. The proportion of Hb A_2 (4.1%) was slightly above the normal range (2.5 – 3.5%). The abnormal component, which represented 17% of the total haemoglobin, was isolated in the carbonmonoxy form on DEAE Sephadex[10] and further purified, for structural studies, by paper electrophoresis[11].

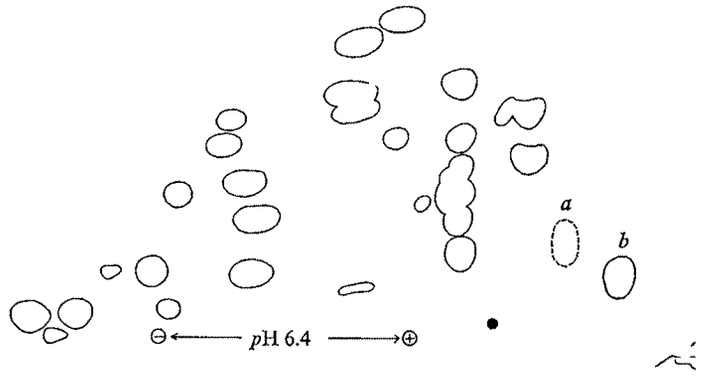

Fig. 1 Fingerprint of the soluble tryptic peptides of the globin from Hb Moscva. Electrophoresis at *p*H 6.4, 53 Vcm^{-1} for 1 h; ascending chromatography in pyridine–isoamyl alcohol–water (6:6:7, by volume) for 18 h. Peptides were located with 0.2% (w/v) ninhydrin containing 1% (v/v) pyridine and with the specific staining reagent (Sakaguchi) for arginine-containing peptides. ●, Origin; *a*, position of β^{A}TpIII; *b* = β^{Moscva}TpXIII. The variant βTpIII was isolated by paper electrophoresis at *p*H 6.4 (61 V cm^{-1}, 1 h).

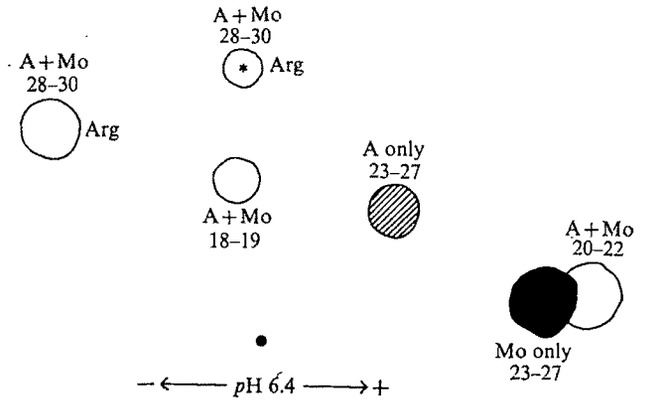

Fig. 2 Fingerprint of the thermolysin peptides of βᴬTpIII (A) and βTpIII from Hb Moscva (Mo). Electrophoresis at *p*H 6.4, 53 V cm^{-1} for 45 min; ascending chromatography and location of peptides as in Fig. 1. The peptide β^{Moscva}23–27 was purified from β20–22, for sequence studies, by paper electrophoresis at *p*H 9 (1% (w/v) $(NH_4)_2CO_3$, 44 V cm^{-1}, 1 h). ●, Origin.

*An electrically neutral peptide with an amino acid composition similar to that of the positively-charged peptide β28–30 (Leu-Gly-Arg); it amounted to 6% of total β28–30 and was thought to represent a minor reaction product, produced between ninhydrin and the guanidinium side chain of arginine β30, during location of βTpIII after its preparation on paper.

On the fingerprint of the tryptic digest of Hb Moscva, prepared by standard techniques[12], peptide βᴬTpIII (β18–30) (*a* in Fig. 1) was replaced by a new, more negatively charged peptide (*b* in Fig. 1). The amino acid composition of the new peptide (Table 1) resembled that of βᴬTpIII except for a substitution of one of the three glycine residues β24, 25 or 29, (Table 2) by an aspartic acid residue. Asparagine is converted to aspartic acid during the hydrolysis which precedes amino acid analysis; a Gly → Asn substitution could, however, be excluded because of the increased negative charge of the variant peptide.

To determine which of the three residues had been replaced, the variant βTpIII was digested with thermolysin and the digest fingerprinted at *p*H 6.4. Comparison of the fingerprint with that from βᴬTpIII (Fig. 2) showed that the peptide βᴬ23–27 (Val-Gly-Gly-Glu-Ala) had been replaced by another, more negatively charged peptide, the amino acid composition of which (Table 1) indicated that one residue of glycine (β24 or β25) had been replaced by one of aspartic acid. Dansyl-Edman degradation[13] showed the sequence β23–25 to be Val-Asp-Gly and the amino acid substitution in Hb Moscva, therefore, to be β24 (B6) Gly → Asp.

Table 1 Amino acid composition of the tryptic peptides β18-30 and the thermolysin peptides β23–27 from Hb A and Hb Moscva.

Amino acid	Peptide			
	βTpIII	(β18–30)	β23–27	
	A	Moscva	A	Moscva
Asp	2	3.0	—	0.9
Glu	2	2.0	1	1.0
Gly	3	2.0	2	1.0
Ala	1	1.2	1	1.0
Val	3	3.0	1	1.0
Leu	1	1.2		
Arg	1	1.1		

Peptides were hydrolysed with constant-boiling HCl for 18 h at 108° C in sealed evacuated tubes. After removal of the excess HCl in a rotary evaporator, the hydrolysates were analysed using a Locarte amino acid analyser.

Measurements of the oxygen affinity of isolated Hb Moscva showed it to have a slightly lower oxygen affinity than Hb A (Fig. 3), but with a near normal Bohr effect and haem–haem interaction.

All known normal globin chains have a Gly in position B6, with four exceptions (α-chains of mouse NB and grey kangaroo, one of the midge and one of the plant haemoglobins)[14,15]. M.F Perutz has examined, with us, the possible consequences of the substitution in Hb Moscva using his atomic model of human haemoglobin. B6 is in a densely packed region of the molecule where a side chain could not be easily accommodated without forcing apart the B and E helices. In the three unstable haemoglobins Riverdale-Bronx[16] Savannah[17] and Moscva, the glycine residue β24 (B6) is replaced by one of arginine, valine and aspartic acid, respectively. It is probable that these substitutions disturb the spatial relationships of the haem with the adjacent polypeptide chain; for example, J. Peisach observed that the EPR spectrum of met–Hb Riverdale-Bronx differs from that of met–Hb A (cited in ref. 16). Hb Savannah shows an increased dissociation into αβ dimers[17], suggesting that the α1β2 contact may be indirectly affected.

It is not possible to predict how these substitutions may affect the oxygen affinity. Hb Riverdale-Bronx shows, in contrast to Hb Moscva, a higher oxygen affinity than HbA (P. A. L., un-

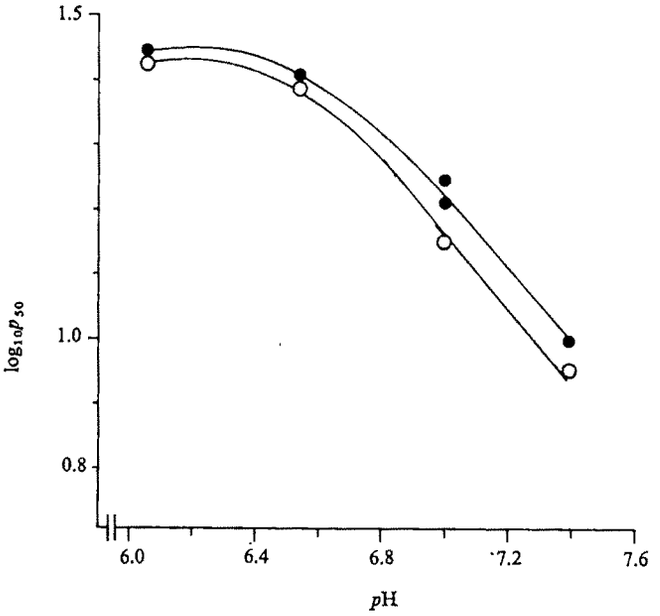

Fig. 3 Values of $\log_{10}p_{50}$ for, ○, Hb A and, ●, Hb Moscva at various *p*H values; p_{50} is the pressure of O_2 in mm Hg required to attain half saturation of the haemoglobin. The CO-Hb was concentrated to about 5% (w/v) by ultrafiltration at 4° C and then equilibrated with 0.05 M potassium phosphate buffer *p*H 8.6, by gel filtration on a 1.0 × 9.0 cm column of Sephadex G25 (coarse). The CO-Hb was converted to the oxy-form[18] and oxygen dissociation curves were recorded by the automatic method of Imai *et al.*[19] using 0.1% (w/v) haemoglobin solutions in 0.1 M potassium phosphate buffers of various *p*H values containing 0.5 mM EDTA. The measurements were made at a temperature of 23° C using monochromatic light of wavelength 474 nm. The values of p_{50} were determined from the dissociation curves and the values of *n*, the exponent of the Hill equation, were determined from the slope of the Hill plots. The curves were nearly parallel showing that the Bohr effect, which is represented by the slope of the curve $d(\log_{10}p_{50})/d(pH)$, is the same for Hb Moscva and Hb A.

Table 2 Amino acid sequence of the peptide βTpIII from Hb A and Hb Moscva

Residue No.	18	19	20	21	22	23	24	25	26	27	28	29	30
Helical No.	A15	B 1	B 2	B 3	B 4	B 5	B 6	B 7	B 8	B 9	B10	B11	B12
Residues													
Hb A	Val	Asn	↓Val	Asp	Glu	↓Val	Gly	Gly	Glu	Ala	↓Leu	Gly	Arg
Hb Moscva	Val	Asn	↓Val	Asp	Glu	↓Val	Asp	Gly	Glu	Ala	↓Leu	Gly	Arg

The arrows indicate the positions of hydrolysis by thermolysin (1 mg μmol^{-1} peptide); the bond between Glu 22 and Val 23 was only 52% hydrolysed in 5 h at 37° C but was completely split in 8 h at 50° C.

published) but both have a near-normal Bohr effect and haem–haem interaction.

Note added in proof: After this manuscript was submitted, we identified a third unstable haemoglobin from Russia. Its substitution was β106 (G8) Leu–Pro. This variant has been found independently in the United States in two unrelated persons as Hb Casper[20] and in the United Kingdom in one individual as Hb Southampton[21].

Endocytotic formation of rat brain synaptic vesicles

THE present knowledge and theories regarding the fate of synaptic vesicles was reviewed by Holtzman *et al.*[1]. Using electron microscopy it has been found that a marker protein (horseradish peroxidase) was incorporated into vesicles of frog neuromuscular junctions by microinvagination of the synaptic plasma membrane[2–5] and also into brain synapses[6]. Heuser and Reese[2] have put forward a model postulating recirculation of synaptic vesicle structural materials. Thus, during release of neurotransmitter into the synaptic cleft the vesicle membrane should fuse with the presynaptic membrane, and then vesicles could be reformed by invaginations of the synaptic plasma membrane distant from the synaptic cleft.

We have investigated whether synaptic vesicles could be labelled after intracerebral injection of a marker protein. Rats were injected intracisternally with bovine serum albumin (BSA) and after isolation of the synaptic vesicle fraction and specific quantitative assay of its BSA content, the synaptic vesicles were found to be enriched with the label in an endocytotic process dependent on time and affected by barbiturates.

Thirty-five-day-old rats in groups of eight were injected with 2.2 mg BSA in 10 μl 0.9% NaCl, into the cisternae magna by the suboccipital route. The rats were anaesthetised with equal volumes of oxygen and carbon dioxide during the injection. They recovered less than half a minute after removal of the anaesthetic. After 5, 120 or 240 min the rats were decapitated. Their brains were homogenised in isotonic sucrose: and by sedimentation rate separations crude synaptosomal–mitochondrial subfractions (cmf) were produced. These were osmolysed in water and separated on a density gradient by ultracentrifugation[7,8]. The 0.2/0.4 M sucrose density gradient interface and the 0.4/0.6 M interface were removed, diluted with water and centrifuged to give synaptic vesicles (ves) and synaptic vesicles heavily contaminated with microsomes (m-ves), respectively. The ves and m-ves layers have been identified by electron microscopy[9] and by analysis of an antigen characteristic of vesicles[7]. No differences were found between the three labelling periods with respect to the amount of vesicle antigen. The brain homogenate (hom) containing both free and bound BSA, and the subcellular fractions cmf, ves and m-ves containing only bound BSA were solubilised in Triton X-100 and analysed for BSA content by rocket immunoelectrophoresis.

Figure 1 shows that the synaptic vesicle subcellular fractions are enriched in BSA both compared with the parent cmf fraction and the microsome-contaminated m-ves fraction. The enrichment of BSA in the synaptic vesicle fraction was greatest at 120 min labelling time, but the decrease with 240 min labelling time paralleled the decrease in hom and cmf. When BSA was added directly to prepared, until then unlabelled, hom and cmf fractions, the specific BSA content in subsequent prepared ves fractions was less than 0.08 μg BSA per mg protein (lower detection limit), ruling out unspecific adhesion to subcellular particles.

We have compared the specific BSA content in the synaptic vesicle fraction between control groups, and groups of rats

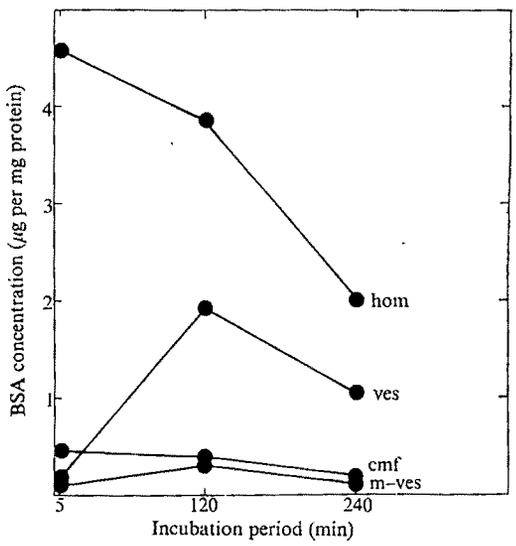

Fig. 1 Specific concentration of suboccipital injected BSA in fractions of rat brains at different incubation periods. Subcellular particles were solubilised in 2% Triton X-100, 10 mM phosphate, 1 mM EDTA and 1% Trasylol (a protease inhibitor), adjusted to *p*H 8.5. After 2 h at 4° C the supernatant from an ultracentrifugation at 6,000,000*g* × min was used for rocket immunoelectrophoresis. Here we used 0.17 μl rabbit anti-BSA cm^{-2}, detecting between 5 and 400 ng BSA in samples of 20 μl solubilised material[10].

anaesthetised with barbiturate during a labelling period of 120 min. The specific contents of BSA in ves from rats treated with barbiturate (Nembutal) were only 66% of that of the controls.

As the vesicles were enriched compared with both parent (cmf) and sister (m-ves) fractions assayed, the BSA-containing particles must be an integral part of the ves fraction. The BSA uptake may be explained by pinocytotic *de novo* formation of the vesicles from the synaptic plasma membrane as well as by transitory fusion of preformed vesicles with the synaptic membrane during release of transmitter into the synaptic cleft[11]. But taken together with the electron microscopic observations of micropinocytosis in the central nervous sytem, these results indicate that at least a part of the synaptic vesicles have been formed or reformed from the synaptic plasma membrane in an endocytotic process. Anaesthesia decreased the BSA content of the vesicles to 66% possibly by impeded vesicle formation. It has also been shown that electrical stimulation of peripherial nerves increased the endocytotic uptake of horseradish peroxidase[3]. Thus, it should be possible to include the quantitative measurement of endocytotic formation of brain synaptic vesicles in the armament of the neuropharmacologist.

Chemical transfer of learned colour discrimination in goldfish

THE literature describing chemical transfer of learned information has been characterised by contradictory findings during the past ten years[1-3].

We have, however, recently managed to obtain reliable and repeatable results with goldfish, and we report below two experiments which were designed to test the specificity of chemical information transfer.

The reliability and direction of transfer has been reported to be influenced by the amount and type of extract injected, the amount of training of the donor and recipient animals and the time between injection and test[4-7]. These same variables have been important in our own work with goldfish[8]. We have shown, for example, that very small concentrations (1 μg) of nucleic acid extracts from trained donors produce stronger transfer effects than higher concentrations, when compared with injections of the same concentrations from untrained animals. Overtraining of the donor animals also has been shown to have marked effects on the degree of transfer in recipient animals[9].

The avoidance learning task in our experiments was similar to the task required of fish in the shuttle-box described by Horner *et al.*[10] except that two coloured lamps served as the conditioned stimuli. The four shuttle-boxes were rectangular plastic aquaria (78×15×15 cm) equipped with trapezoidal-shaped barriers dividing the boxes into two compartments. Each box had graphite electrodes along the sides to deliver an electric shock. Photo cells at each end of the barrier monitored the response and registered the side of the shuttle-box containing the fish for each trial. The task for the fish was to learn to anticipate a mild (5 V a.c.) electric shock by swimming over the barrier to the other compartment whenever one of two coloured signals (red or green) was presented. All stimulus and response contingencies were controlled and recorded by automated circuitry.

The two experiments below differed in the consequences of responding to the wrong signal, the amount of training given the donor animals and the number of groups of recipient animals. In the first experiment, fish which would later become recipients of the nucleic acid extract from donor animals were trained in a red-green avoidance discrimination. The red signal was presented for 20 s, after which a pulsed electric shock was delivered. Whenever the green signal was presented, it remained on for 30 s and no shock was delivered, regardless of the fish's reaction to it. We designate this as a R+G$_0$ discrimination to differentiate it from a R+G− task where response to green was punished. All fish in both experiments were obtained from local suppliers and were 7–8 cm long. They were housed for one week in a 400 l aquarium and later transferred to individual 6 l aquaria which were supplied with filters. Water temperature was maintained at 20° C.

In the first experiment 74 donor fish (*Carrasius auratus*) were trained in a R+G− discrimination and seven to a G+R− task for 3 d (100 trials each day, 50 red, 50 green,

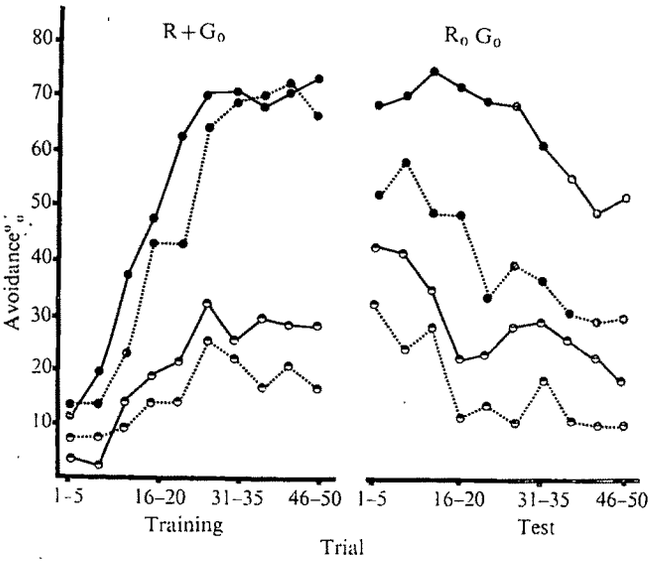

Fig. 1 Action of nucleic acid extracts on two groups of goldfish trained in a red-green avoidance learning task (R+G$_0$). The upper curves on the left (solid black dots) show the percentage avoidance to the positive red stimulus while the bottom two curves on the left (black and white dots) show the response to the incorrect green stimulus. The effect of the dissimilar injection is shown by the set of curves on the right when the same fish were tested under extinction conditions (R$_0$G$_0$). The solid line fish were injected with extract from R+G− trained donors while the broken line fish were injected with G+R− trained extract.

randomly presented). A large number of donor animals were trained in order to have enough extract for dose-response studies. Each trial consisted of the onset of the red or green stimulus lamp on the side of the box containing the fish. When the positive stimulus (R+ or G+) was presented, a 5 V a.c. pulsed shock was delivered (1 s^{-1}, 80 ms duration) 20 s later, unless the fish swam over the barrier into the other compartment. When the negative stimulus (R− or G−) was presented, the animal could avoid shock by staying in its compartment. If the animal responded during the negative stimulus presentation, it was shocked until it returned to the original side. In the R+ or G+ trials, the shock was limited to 10 s when the fish failed to escape. The intertrial interval was 30 s.

Twenty-four hours after this 3 d training period, the fish were decapitated, their brains extracted and placed in liquid nitrogen. The hot-phenol procedure[8] was used to extract nucleic acids from the brain tissue. This method yielded a RNA/DNA mixture of about 300 to 400 μg per fish brain. Only fish that had reached at least the 50% avoidance level to the positive stimulus were used in the extraction procedure.

Two groups of 23 fish each, designated to become recipients, were trained to the R+G_o discrimination described above for one day or 100 trials (50 red, 50 green). Immediately after this training, each fish was injected with 1 μg of extract in 10 μl of saline. The injection was intracranial into the large cranial cavity over the brain. Using a blind procedure, one group was injected with extract from the R+G− trained donors and the other with G+R− extract. They were tested 24 h later for 100 trials under extinction conditions (R_oG_o).

Both groups reached about the 70% avoidance level in responding to the positive stimulus (R+) at the end of training (Fig. 1). Although there was some generalisation to the G_o stimulus (about 25% responding), discrimination is obvious. The effect of the intracranial injection from differentially trained donors was apparent in the test trials on the next day. Fish receiving extracts from similarly trained donors remained at a relatively high level during the extinction trials while fish receiving extract from the G+R+ or dissimilarly trained donors showed a much lower level of performance. This difference is statistically significant at the $P<0.01$ level.

Although the results of the first experiment show a dramatic injection effect, they can only be regarded as suggestive evidence for specific information transfer because of a difference in performance level of the donor animals in the R+G− and G+R− tasks. Since the R+G− discrimination is easier to learn, it can be argued that the observed negative transfer may be due to the different number of shocks received by the G+R− donor animals. The complete factorial design of the second experiment makes this possibility highly unlikely.

In the second experiment, two groups of donor animals were trained as before except that an overtraining procedure was used. Overtraining of the donors has been shown to maximise transfer in a single-stimulus avoidance training situation. The advantage of overtraining is that it equalises asymptotic performance of the R+G− and G+R− donor groups although it does not ensure that both groups receive the same number of shocks since the R+G− animals reach their asymptotic level (90–95%) faster than the G+R− donors. They were trained either on a R+G− or a G+R− task for 5 d (100 trials d^{-1}), rested for 2 d and further trained for 2 d. Immediately after this training their brains were extracted and processed as before. All donor fish had reached at least the 50% avoidance level.

Four groups of fish, designated as recipients, were trained for a 1 d, 100 trial session. There were two R+G− groups and two G+R− groups, each with 15 fish. Immediately after this training, each animal was intracranially injected with 1 μg of extract from donor animals that were similarly or dissimilarly trained. Twenty-four hours after this injection all animals were given 100 test trials under extinction conditions (R_oG_o).

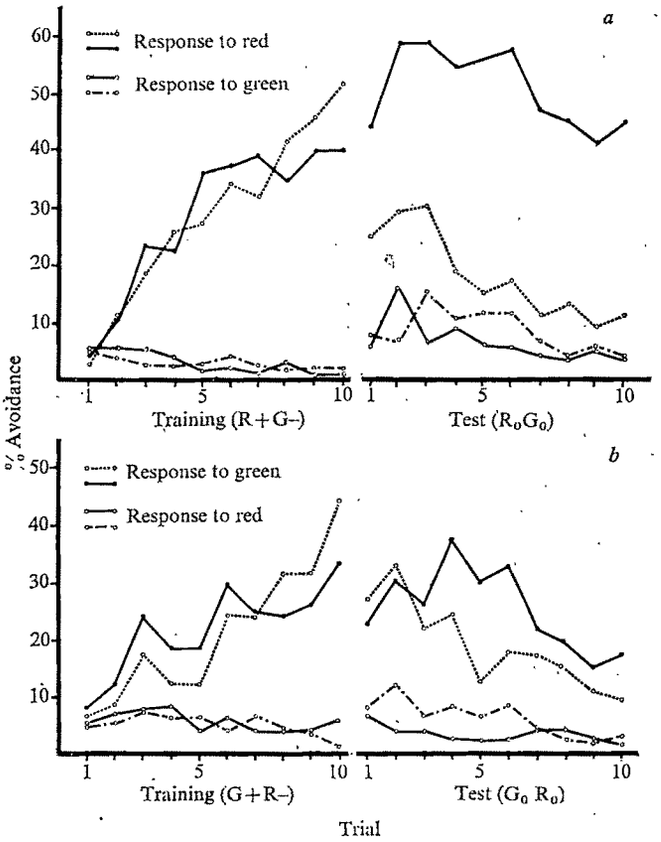

Fig. 2 *a*, Action of nucleic acid extracts on two groups of goldfish trained in a red-green avoidance learning task (R+G−): the upper two curves on the left show the percentage avoidance to the positive red stimulus while the bottom two curves on the left show response to the incorrect green stimulus. The effect of the dissimilar injection is shown in the right set of curves where the same fish were tested under extinction conditions (R_oG_o). The solid line fish were injected with extract from R+G− trained donors while the broken line fish were injected with extract from G+R− trained donors. *b*, Action of nucleic acid extracts on two groups of goldfish trained in a green-red avoidance learning task (G+R−). The upper two curves on the left show the percentage avoidance to the positive green stimulus while the bottom two curves on the left show the response to the red stimulus. The effect of the dissimilar injection is shown in the set of curves to the right when the same fish were tested under extinction conditions (G_oR_o). The solid line fish were injected with G+R− trained extract while the broken line fish were injected with extract from R+G− trained fish.

Figure 2 shows the training and test performance of the four recipient groups. The divergent effects of the injections are apparent for both red-trained and green-trained groups but are particularly striking for the R+G− groups (Fig. 2*a*). Fish receiving extract from animals trained in the identical task improved in performance, while those receiving extract from the opposite trained donors show a marked decline.

Figure 2*a* shows that the difference between the groups in the test trials was due to both the positive transfer on the R+G− trained/R+G− injected group and a negative transfer on the R+G− trained/G+R− injected group. This distinction is not observed in the G+R− recipients where the major part of the difference after injection is caused by the decline in performance of the G+R− trained/R+G− injected group.

The statistical significance of these findings was confirmed

by a five-way analysis of variance with repeated measures on three factors. The difference in performance to the positive stimulus between groups receiving extract from similarly or dissimilarly trained donors is significant at the $P<0.001$ level. Not only is response to the positive stimulus affected by the type of extract, but there is also a tendency for the response to the negative stimulus to be affected as well, although to a much lesser degree.

We are puzzled by the apparent interaction with colour *per se*. The major effect is seen with the red-trained groups. It is possible that this difference is associated with the relatively greater difficulty fish have in learning the avoidance response in the G+R− task. This colour-sensitivity difference between red and green performance has been observed in all studies of the red-green discrimination in this laboratory. The difference persists even when the two stimuli are equated for intensity. An additional control group with extracts from donors trained on an avoidance task with an entirely different set of stimuli might have added to our understanding and assessment of the differences in each pair of subgroups.

The results of both these experiments are consistent with the hypothesis that the extract contains chemically coded specific information which facilitates or inhibits performance. These results are also consistent with other data from this laboratory where similar designs were used in a single stimulus task[9]. Two groups of fish were trained to make avoidance responses to a light-onset signal. They were then injected with extract from donors that were similarly (light-onset) or dissimilarly (light-offset) trained. The test trial performance showed the same divergence in performance as observed here.

In another complete factorial study we conducted, where the recipient animals were overtrained for 3 d (also a red-green task), the striking difference observed in the above two experiments failed to appear. Although a positive transfer is more difficult to achieve in animals already performing at the 80–85% level after 3 d of training, a negative transfer, as was found in the first experiment, is possible but does not appear when the recipients are overtrained. It is possible that well-consolidated information is not as susceptible to chemical interference as has been observed in the puromycin consolidation studies of memory[11–12].

We are planning experiments to further characterise the nucleic acid extracts responsible for the information transfer.

This work was aded by grants from the Deutsche Forschungsgemeinschaft and from Carter Wallace Inc. The authors thank Professor S. Hollman of the Institut fur Physiologische Chemie der Universitaet and Professor H. Reinauer of the Diabetesforschungsinstitut an der Universitaet Duesseldorf for advice and assistance.

Influence of local hydrophobic environment on acid dissociation constants of coordinated water molecules

The hydration of carbon dioxide by Zn(II) carbonic anhydrase is thought[1,2] to occur through a mechanism in which a hydroxyl group coordinated to the zinc atom has an important function. As a consequence, the *p*K of the conjugate acid coordinated water molecule has been the subject of some discussion[2,3]. In Zn(II) (ref. 4) and Co(II) (ref. 5) carbonic anhydrase, the water molecule bound to the metal ion, apparently has a *p*K in the range 6.9–7.9, which is two units lower than the *p*K range quoted[6] for the first protolysis of $[Zn(H_2O)_6]^{2+}$ and $[Co(H_2O)_6]^{2+}$.(The *p*K values quoted for $[M(H_2O)_6]^{2+}$ exhibit a considerable variance and have been determined under a variety of experimental conditions. When M = Co, Ni, Cu and Zn mean *p*K values of 9.8, 10.3, 7.8 and 9.5, respectively, are derived from the range of values quoted at zero ionic strength and at 298 K (*p*K values for all four metal ions in 1 M $NaClO_4$ are not available).)

Structural studies[7] show that the zinc atom in Zn(II) carbonic anhydrase is situated at the bottom of a cleft, lined with hydrophobic groups, in the protein molecule, and also that it is tetrahedrally coordinated by three imidazole groups and one water molecule. It has been postulated that this local hydrophobic environment is largely responsible for the decreased *p*K of the coordinated water molecule[2,3]. Although the variation of the *p*K of coordinated water with the metal ion character and environment is well known[8,9], there seems to be no report of a study in which this postulate may be tested.

Here we report a study in which the environment of a water molecule is changed from hydrophilic to hydrophobic for a range of metal ions, whilst the ligand donor atoms and metal ion coordination number remain constant and the coordination geometry almost so.

Divalent cobalt, nickel, copper and zinc all form stable 1 : 1 complexes with both 2, 2′, 2″-triaminotriethylamine (tren) (ref. 10) and 2, 2′, 2″-tri (N, N-dimethylamine) triethylamine (Me_6tren) (ref. 11) in aqueous solution. The complexes are five coordinate[12–14] with the general formula $[MtrenH_2O]^{2+}$ and $[MMe_6trenH_2O]^{2+}$ with the exception of the species $[Ni\ tren(H_2O)_2]^{2+}$. An examination of space filling models based on the known solid state structures of the[15] $[M\ trenNCS]^+$ and [11] $[MMe_6trenBr]^+$ ions reveals that the coordinated water molecule in $[M\ trenH_2O]^{2+}$ is closely adjacent to the hydrophilic primary amine groups of the tren ligand, whereas the coordinated water molecule of $[MMe_6trenH_2O]^{2+}$ is sterically crowded by the hydrophobic methyl groups of the Me_6tren ligand (Fig. 1). Thus, these complexes provide an opportunity for the examination of both the effects of the metal ion and of the change of environment on the *p*K of the coordinated water molecule.

The complexes undergo protolysis as follows:

$$[M\ trenH_2O]^{2+} + H_2O \rightleftharpoons [M\ trenOH]^+ + H_3O^+$$

$$[MMe_6trenH_2O]^{2+} + H_2O \rightleftharpoons [MMe_6trenOH]^+ + H_3O^+$$

Apparent *p*K values were determined by sodium hydroxide titration, under nitrogen, of 5×10^{-3} M complex solutions in aqueous 1M sodium perchlorate media, using a Radiometer combined glass and calomel electrode, and a Radiometer

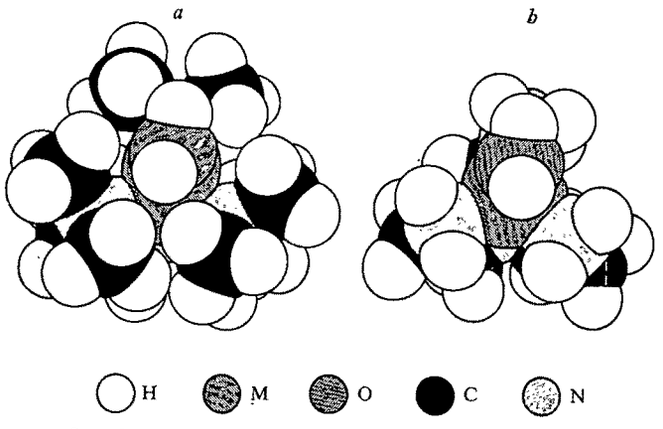

Fig. 1 Space filling models of $[MMe_6trenH_2O]^{2+}$ (*a*) and $[MtrenH_2O]^{2+}$ (*b*).

PHM4 or PHM26 *p*H meter. Sodium hydroxide was added with an Agla microsyringe. Complex solutions were prepared in carbon dioxide-free water by the addition of equimolar amounts of metal perchlorate salt and polyamine ligand solution; except when the solid complex $[MMe_6trenC10_4]C10_4$ (M = Ni, Co, Cu) was used directly. (The titration data were consistent with rapid dissociation of the coordinated perchlorate to produce $[MMe_6trenH_2O]^{2+}$ upon dissolution.) Titration curves were corrected for the concentration of uncombined hydroxyl ion by reference to a titration of 1M sodium perchlorate alone. Apparent *p*K values were calculated from plots of *p*H against log ([salt]/[acid]) by a least squares regression analysis. Each complex was titrated in duplicate at 288 K, 298 K and 308 K thus facilitating the computation of ΔH^0 and ΔS^0 for the protolysis reaction. The results obtained are summarised in Table 1.

In Fig. 2 the *p*K (298 K) values for the $[MtrenH_2O]^{2+}$ and $[MMe_6trenH_2O]^{2+}$ series show similar dependences upon the nature of the central metal ion, the general trends in which persist for each series over most of the solution liquid range as indicated by the thermodynamic data. The *p*K for six coordinate $[Ni\ tren(H_2O)_2]^{2+}$ cannot be strictly compared with those of its five coordinate cobalt, copper and zinc analogues. The titration data, however, show the first *p*K for this species to be greater than 11.0, and this datum is shown by the broken box in Fig. 2. The M–Br bond distances[13] for $[MMe_6trenBr]^+$ are also plotted in Fig. 2 and there exists a strong similarity between the dependence of these distances upon the metal ion (which has been explained in terms of d orbital occupancy[13]) and the variation in *p*K values exhibited by the $[MMe_6trenH_2O]^{2+}$ series. On the assumption that the M–OH_2 distances exhibit a similar variation it would seem that increasing metal ion attraction for the coordinated water molecule results in a decrease in *p*K. It is noteworthy that there is no correlation between *p*K value and any of the M–N distances[13] in the $[MMe_6trenBr]^+$ series.

The *p*K variation between the $[MtrenH_2O]^{2+}$ and $[MMe_6trenH_2O]^{2+}$ series might arise either because of differences in the environment of the coordinated water molecule in each case, or because of differences in electron donation to the central metal atom between the $-NH_2$ groups of tren and the $-N(CH_3)_2$ groups of Me_6tren, or a combination of these two factors. The crystal field splitting for $[Co\ trenH_2O]^{2+}$ has been shown to be greater than that of its methylated analogue[12], and on this basis the greater electron donation to the metal ion in the $[MtrenH_2O]^{2+}$ series might result in a higher *p*K for these complexes than for the $[MMe_6trenH_2O]^{2+}$ series. This is the trend observed and consequently it is evident that the *p*K variation cannot be attributed solely to variation of the local environment of the coordinated water molecule in the two series, although it seems that this last factor is of major importance.

A reasonable linear free energy relationship (LFER) characterised by an isoequilibrium temperature of 269 ± 16 K, exists (Fig. 3) for the thermodynamic data of Table 1. This LFER indicates that a single major factor accounts for the difference between the entropy dominated $[MtrenH_2O]^{2+}$ *p*K values and the enthalpy dominated $[MMe_6trenH_2O]^{2+}$ *p*K values. The systematic displacement of the data about the LFER regression line is a consequence of ΔH° and ΔS° becoming increasingly positive in the order Cu < Co < Zn for both series of complexes, and indicates the specific metal ion perturbation of the major LFER relationship. The isoequilibrium temperatures for the isometallic $[MtrenH_2O]^{2+}$ and $[MMe_6trenH_2O]^{2+}$ pairs are 239 K (Co), 261 (Cu) and 250K (Zn).

The thermodynamic differences between the two series of complexes are summarised in Table 2. If, following the method of Hepler[17], ΔH° and ΔS° are considered as sums of internal contributions, arising from interactions within the metal complexes, and external contributions arising from interactions between the complex and the solvent, one may write:

$$\Delta H^\circ = \Delta H^\circ_{int} + \Delta H^\circ_{ext}$$
$$\Delta S^\circ = \Delta S^\circ_{int} + \Delta S^\circ_{ext}$$

Table 1 Apparent thermodynamic data at 298 K for the acid dissociation of a single water molecule coordinated to tren and Me_6tren complexes

Complex	*p*K ± (s.e.)	ΔH^0 ± (s.e.) kJ mol^{-1}	ΔS^0 ± (s.e.) J K^{-1} mol^{-1}
$[Co\ trenH_2O]^{2+}$	10.22 ± 0.01	+ 0.9 ± 2.7	−192.7 ± 9.1
$[Cu\ trenH_2O]^{2+}$	9.37 ± 0.01	−13.6 ± 1.9	−225.0 ± 6.4
$[Zn\ trenH_2O]^{2+}$	10.26 ± 0.02	+11.9 ± 1.9	−156.5 ± 6.4
$[CoMe_6trenH_2O]^{2+}$	8.80 ± 0.04	+33.9 ± 1.9	− 54.5 ± 6.4
$[NiMe_6trenH_2O]^{2+}$	9.53 ± 0.01	+33.9 ± 1.9	− 68.7 ± 6.4
$[CuMe_6trenH_2O]^{2+}$	8.52 ± 0.01	+28.8 ± 1.9	− 66.5 ± 6.4
$[ZnMe_6trenH_2O]^{2+}$	9.00 ± 0.01	+49.2 ± 1.9	− 7.2 ± 6.4

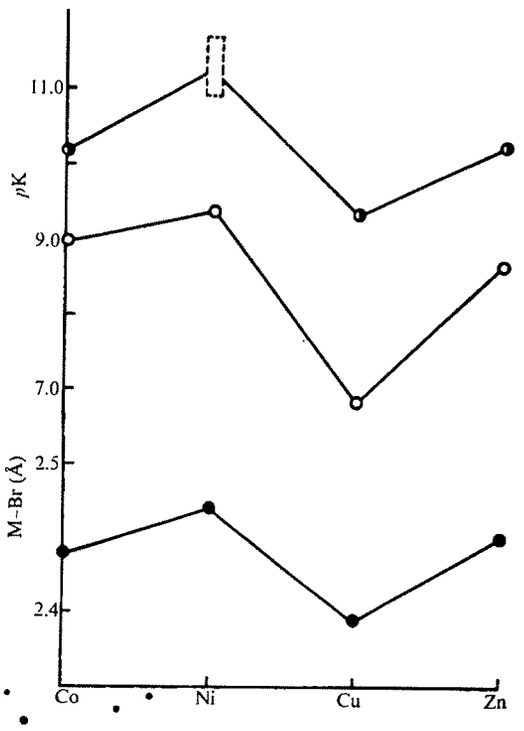

Fig. 2 Apparent *p*K values of $[MtrenH_2O]^{2+}$ (◑) and $[MMe_6trenH_2O]^{2+}$ (○); and the M–Br distances in $[MMe_6trenBr]^+$ (●) when M = Co, Ni, Cu and Zn.

Further, Pitzer[18] has shown that for the dissociation of a weak acid $\Delta S°_{int} \approx 0$. Thus, the differences in $\Delta S°$ between equivalent members of the two series of complexes are most probably entirely due to differences in the external contributions to the standard entropies of protolysis. Examination of Table 2 shows that the values of $\Delta S°_{Me_6tren} - \Delta S°_{tren}$ are very similar for Co, Cu and Zn; indicating that the differences between $[MtrenH_2O]^{2+}$ and $[MMe_6trenH_2O]^{2+}$ are caused by a similar change in environment for each metal.

Table 2 Differences in apparent thermodynamic quantities between Me_6tren and tren complexes

Metal	$pK_{Me_6tren} - pK_{tren}$	$\Delta H°_{Me_6tren} - \Delta H°_{tren}$	$\Delta S°_{Me_6tren} - \Delta S°_{tren}$
Co	−1.42	33.0 (± 4.6)	138.2 (± 15.5)
Cu	−0.85	41.4 (± 3.8)	158.5 (± 12.8)
Zn	−1.26	37.3 (± 3.8)	149.3 (± 12.8)

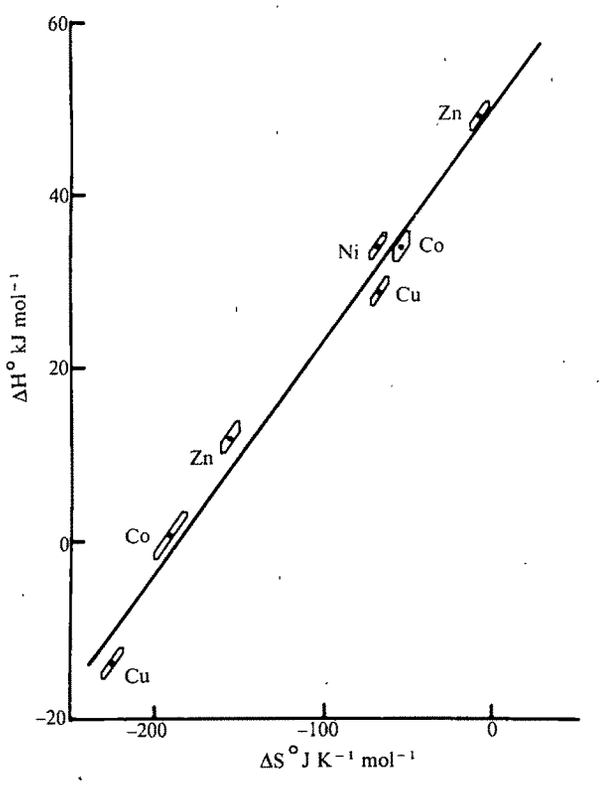

Fig. 3 The linear free energy relationship for the protolysis of $[MMe_6trenH_2O]^{2+}$ (upper set of points) and $[MtrenH_2O]^{2+}$ (lower set of points) when M = Co, Ni, Cu and Zn. The error estimates were calculated by the method of Mandel and Linnig[22].

The most probable environmental difference between $[MtrenH_2O]^{2+}$ and $[MMe_6trenH_2O]^{2+}$ is in the degree of ordering of solvent water molecules close to these complexes. It seems from two partly related considerations that the degree of solvent water ordering about $[MMe_6trenH_2O]^{2+}$ is likely to be the greater. First, the surface of $[MMe_6trenH_2O]^{2+}$, with the exception of the coordinated water molecule, is composed of hydrophobic alkyl groups—a situation generally considered to engender the formation of an ordered 'ice-like' structure in solvent water adjacent to such a surface[19,20] as is observed in the vicinity of the zinc atom in carbonic anhydrase[7]. By contrast the hydrophilic amine groups of $[MtrenH_2O]^{2+}$ seem unlikely to affect the adjacent water structure significantly[19]. Second, the charge density on the surface of the two complexes, particularly in the vicinity of the coordinated water molecule seems likely to be greater in the case of $[MtrenH_2O]^{2+}$ as this species is smaller (Fig. 1) and also because of the polarity of the amine groups. According to Frank and Wen[19], large ions with a low surface charge density are surrounded by a layer of water, disordered to an extent approximately proportional to the charge density (region B in the terminology of Frank and Wen[19]) as a consequence of two competing influences; the ionic charge solvent water dipole interaction, and the structural orientating influence of neighbouring bulk water molecules acting upon solvent water molecules adjacent to the ion. It seems that as a result of its greater surface charge density and because of the hydrophilic nature of the amine groups, solvent water adjacent to $[MtrenH_2O]^{2+}$ will be less ordered and the decrease in entropy greater upon protolysis than will be the case for $[MMe_6trenH_2O]^{2+}$ consistent with the observed trend in $\Delta S°$.

These conclusions lend some support to the suggestion that the low pK values for the coordinated water molecule in carbonic anhydrase[2] and also for other weak acid groups conjugated to proteins[21] are, in part, a consequence of their hydrophobic environment. It should be noted, however, that the systems studied here are structurally simple and that the relative importance of hydrophobic effects in these systems may differ considerably from the importance of such effects in the protein systems.

Prolongation of skin allografts after oral application of ALS in rats

THE potency of anti-lymphocytic serum (ALS) in prolonging skin allografts has been well investigated. Four different routes of administration are being used: intravenous[1], intraperitoneal[2], intramuscular[3] and subcutaneous[4]. Every route has its own advantages and disadvantages from the immunological and clinical point of view and these have been discussed elsewhere[5,6]. Oral application of ALS was never tried because it was assumed that intact proteins like gamma globulins are enzymatically metabolised before they pass through the intestinal wall. But we shall demonstrate, that even oral application of ALS can prolong the survival time of skin allografts.

Two different series of experiments were performed, using altogether 65 white male colony-bred Sprague-Dawley rats, weighing 250 g. All animals were grafted with skin from black inbred BD-6 rats. In the first series, animals were fed 1 ml ALS daily, until graft rejection was completed and controls were fed with normal rabbit serum (NRS). In the second series animals were treated orally with 1 ml ALS or 1 ml NRS on days 1, 3 and 5, only. Feeding was by a polyethylene tube placed into the stomach. The effect of oral ALS application was compared with the effect of intraperitoneal administration of ALS or NRS. One group of rats remained entirely untreated. For statistical analysis mean values, standard error of the mean (s.e.m.), and P values according to student's t test were calculated.

ALS was produced in rabbits by 'two pulse' injection of lymphocytes from the thoracic duct and thymus of rats. The first pulse was applied together with complete Freund's adjuvant. The lymphocytotoxic titre of ALS was 1 : 64, and the haemagglutination titre 1 : 4, after one absorption with rat erythrocytes. ALS and NRS both had a protein concentration of 50 mg ml^{-1}.

The results are set out in Table 1. The mean survival time (MST) of skin grafts in rats without any treatment was about 10 d. Intraperitoneal as well as oral application of NRS did not prolong the MST of skin grafts significantly ($P < 0.1$). As expected, i.p. administration of ALS either every day or just on days 1, 3 and 5 increased the MST of skin allografts significantly ($P < 0.001$). But the daily oral application of ALS also prolonged the MST to 26.5 ± 1.9 d; this was 13 d longer than that for control animals treated in the same manner with NRS. When the high dosage of ALS of 1 ml daily was reduced to 1 ml on days 1, 3 and 5, this caused a decrease of the MST from 26.5 ± 1.9 d to 23.4 ± 1.8 d. Nevertheless, skin allografts survived significantly longer ($P < 0.001$) after oral application of ALS then after oral application of NRS, the difference being 10 d.

Table 1 Prolongation of skin allografts after oral and i.p. application of ALS

Group	No.	Treatment	Route	Dose (1 ml)	MST* ± s.e.m. (d)	Median ST† (d)
Series 1						
1	9	ALS	oral	Daily	26.5 ± 1.9	23.8 ± 1.4
2	6	NRS	oral	Daily	13.6 ± 1.7	10.3 ± 0.3
Series 2						
3	10	ALS	oral	Days 1, 3, 5	23.4 ± 1.8	19.2 ± 1.9
4	7	NRS	oral	Days 1, 3, 5	13.1 ± 0.6	12.2 ± 0.75
Controls						
5	9	ALS	i.p.	Daily	31.7 ± 1.2	28.5 ± 1.2
6	5	NRS	i.p.	Daily	12.8 ± 1.1	11.0 ± 0.5
7	10	ALS	i.p.	Days 1, 3, 5	18.6 ± 0.3	17.8 ± 0.2
8	5	NRS	i.p.	Days 1, 3, 5	10.6 ± 0.3	9.6 ± 0.3
9	14	—	—	—	10.1 ± 0.2	9.6 ± 0.2

* Mean survival time.
† Median survival time.

The oral route of application seems to be less effective than the i.p. route when ALS is given daily. The i.p. application of ALS on days 1, 3 and 5 prolonged the MST of skin allografts only to 18.6 ± 0.3 d, whereas after oral treatment, allografts were rejected after 23.4 ± 1.8 d. A statistical analysis, however, does not show significant differences between the groups.

The prolongation of skin allografts after oral application of ALS contradicts the generally held opinion that gamma globulins are metabolised on their way through the gut by digestive enzymes[7,8]. Providing the effect of ALS depends on an interaction with lymphocytes or with the graft, the significant prolongation of the MST after oral application can be explained by a partial absorption of intact protein molecules. Since BSA (refs 9 and 10), horseradish peroxidase[10] or kallikrein[11] are known to be absorbed without biochemical or immunological alterations the absorption of intact gamma globulin is perhaps not surprising. The alternative hypothesis, that orally administered ALS causes lesions in the intestinal wall which allow protein molecules to leak through, is made highly improbable by histological and macroscopic observations on the intestine. It is, nevertheless, conceivable that ultrastructural changes in the gut wall facilitate the penetration of unaltered gamma globulins. It is also possible that lymphocytes normally invading the lumen of the gut[12] are exposed to ALS there. By this means ALS might reduce the absolute number of lymphocytes without penetrating the intestinal wall.

Preliminary studies in rats and dogs have shown that it is possible to detect xenogeneic globulins in the blood of recipients using Ouchterlony's technique and Sephadex radiochromatography, following oral application of ALS. It is therefore possible that a proportion of unaltered gamma globulins does pass through the intestinal wall. But rats have less proteinase in their gut than dogs and man; this means that ALS is metabolised less in the small intestine of rats than in that of humans. Consequently, more ALS might be absorbed in rats and this may explain the success in prolonging skin allografts after oral treatment.

Apart from this theoretical interest, the oral route may become important for the clinical application of ALS, because the antibody production of orally treated animals seems to be markedly reduced. Whereas the i.p. application of ALS causes the formation of precipitating anti-horse serum protein antibodies in all recipients, oral administration causes precipitating antibodies in only 10% of rats after 14 d of treatment.

The Mechanism of Photosynthesis

C. P. Whittingham

The dearth of literature covering the biochemistry of photosynthesis has prompted the author to put into perspective all aspects of present research. He provides a general view of existing knowledge of the mechanism of the process, as obtained from research in such related sciences as biochemistry and physical chemistry.
Cloth £3.80 net. Paper £1.90 net.

New Second Editions of Three Well Known Titles

Principles of Animal Physiology

Dennis W. Wood

An introductory text which does not distinguish between 'general' and 'comparative' physiology, the emphasis is placed on cellular physiology and the physiology of nerve and muscle and of co-ordination.
Cloth £6.50 net approx. Paper £3.25 net approx.
Probable publication September.

The Biology of Lichens

Mason E. Hale

This is the only unified treatment of lichens available. Emphasis is placed on current areas of research including ultrastructure, physiology, biochemical taxonomy, ecology and chemistry.
Cloth £5.00 net approx. Paper £2.50 net approx.
Probable publication August.

A Biologist's Physical Chemistry

J. Gareth Morris

This book is designed as an aid to undergraduates' understanding of the application of the physico-chemical principles to biological situations. This edition is in SI units and the second chapter 'Units and their usage' has been entirely rewritten.

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, **'Molecular Biology Comes of Age'** looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of **'Molecular Biology Comes of Age'** are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

Chart Art

Koch-Light's 'new' Old Master

This is the 12th edition of the Colourful Metabolic Pathways Chart, with more than 500,000 copies distributed over the years to the biochemical world. No. 12 has some particularly worthwhile new features, but still retains its familiar—easy to understand—basic structure. The inter-relationships of metabolism, particularly those of carbohydrates, fats, and amino acids, are clearly shown.

60 new compounds have been added. Lipid metabolism has been expanded; and several carotenoids and water-soluble vitamins—including visual pigments—incorporated. Back again (by 'popular demand'): the folic acid C-1 pool. Another important new feature: the inclusion of Enzyme Commission (E.C.) reference numbers, which simplifies the identification of the many enzymes involved. Once again the designer responsible for this latest Old Master is Dr. D. E. Nicholson of Leeds University.

matters arising

Nonradioactive silver

SIR,—Lindner *et al.*[1] described the detection of small amounts of radioactive silver isotopes (^{108m}Ag and ^{110m}Ag) in silver bars from an eastern European source. They suggested that the activity may have originated from any one of several causes: nuclear mining, that is, the breaking up of rock before the removal of the ore, using nuclear explosions; neutron irradiation of the ore after it was mined; the introduction of silver isotopes into the melted silver during processing; or irradiation of the silver bars.

Another possibility has been suggested by Boyle[2]. An intimate contact of silver, uranium and light elements such as boron, might produce, through (α, n) reactions, enough neutrons to give measurable events of ^{108m}Ag ^{110m}Ag. This phenomenon could occur in uranium deposits of the vein type, which are found in eastern Europe.

We have checked this speculation by counting specimens of silver ore collected from the Echo Bay Mine (near Port Radium), Great Bear Lake, Canada[3]. Ore samples from this vein-type uranium deposit included two pieces of massive native silver mined from uraninite-rich areas of the 302 Stope, and a third sample from an occurrence of pitchblende, 206A W Drift in the mine, containing veinlets of native silver. The first two samples were counted directly but in the latter case the silver was separated from the ore by dissolution in nitric acid. The silver was therefore in intimate contact with the pitchblende until a few hours before it was counted.

For counting, a 70 cm^3 Ge(Li) γ-ray detector and multichannel analyser were used. The sensitivity was 10 nCi, the same as that of the NaI(Tl) detector used by the Dutch workers. Since we did not possess an anticoincidence array, we were compelled to count for several days in order to achieve this. In all three cases there was no measurable ^{108m}Ag or ^{110m}Ag in the samples. On the basis of the Dutch work, we would have expected to have detected as much as 3 μCi.

We conclude that, at least for our samples, uranium does not produce significant activity in the silver associated with it. In view of the calculated low neutron flux[2], this is not surprising. Our conclusion can probably be applied to similar ore bodies.

R. W. Boyle (personal communication) cannot find any reported nuclear detonations which correlate with the time of origin of the activity as calculated by the Dutch workers. We agree with their current view (personal communication) that the most likely source of the reported activity is the addition of silver tracer to the silver during some stage of the refining process.

Yours faithfully,

N. E. WHITEHEAD

Great Glen Fault

SIR,—Detailed mapping of the regional metamorphic pattern of the central and northern Highlands has led to the conclusion that a post-metamorphic sinistral shift of 160 km must have occurred along the Great Glen Fault[1]. A reappraisal of the considered data suggests, however, that the proposed shift probably represents a minimum estimate; a displacement of 200 km would, for example, fit the data equally well but even this figure cannot be taken as a reasonable upper limit of possible strike-slip movement.

The most likely northward continuation of the Great Glen Fault is through the Walls Boundary Fault in Shetland[2]. This provides a slight curvature in the fault line which seems to have an important geophysical bearing on the displacement problem. Thus, it can be shown[3,4] that a certain discordance in Devonian palaeomagnetism across the Great Glen Fault can be fully explained by incorporating a late or post-Devonian sinistral shift of at least about 200 km. At present, palaeomagnetic results cannot be used to set an upper limit of the actual movement but a displacement of at least 250 km is possible. What is really important at this stage, however, is to stress that a geophysical and a geological method have both led to practically identical palaeogeographic reconstruction of Scotland, which involve a transcurrent movement, at least twice as large as previously suspected along the Great Glen Fault. Consideration of the lower age limit of this movement (provided by palaeomagnetic results) seems to indicate that the Strontian and Foyers granites (K/Ar ages of around 400 Myr, ref. 5) never formed part of the same intrusive complex.

Yours faithfully,

K. M. STORETVEDT
Department of Geophysics, University of Bergen, Norway

DR WINCHESTER replies: Storetvedt's comments are very welcome. The suggested displacement of 160 km was chosen as the optimum fit of the metamorphic patterns in the opposing blocks. A precise metamorphic zonal correlation across the fault is not possible because on opposite sides of the fault, Moinian rocks are concealed beneath Devonian sediments east of Inverness, and beneath Tertiary volcanics in Mull. The zonal pattern may therefore be extrapolated across these areas to fit a post-metamorphic displacement of between 140 and 200 km along the Great Glen Fault, before it becomes impossible to match without requiring an unjustified warping of the metamorphic pattern adjacent to the fault. A displacement of 250 km is therefore not supported by the metamorphic evidence. It is significant, however, that the maximum displacement allowed by the metamorphic pattern, and the minimum shift indicated by Storetvedt's palaeomagnetic work should agree so well.

University of Durham

McCollough colour after effect

SIR,—McCollough[1] demonstrated a striking, long lasting colour after effect. Observers adapted (2–4 min) to a vertical grating of black and orange stripes alternating with a horizontal grating of black and blue stripes. Thereafter a pattern made up of a black and white vertical grating and an adjacent horizontal grating appeared tinted with colours complementary to the adapting colours. The

vertical grating appeared blue-green and the horizontal grating appeared orange.

Piggins and Leppmann[2] repeated the McCollough-type experiment with the adapting pattern stabilised on the retina by the conventional contact lens method. They were unable to build up the after effect with a stabilised image. They concluded that the eye must scan the adapting pattern to generate the after effect, and explanations of the after effect must include 'image motion mechanisms'.

Our experiments show that the after effect requires no retinal image motion. Four observers adapted to a high contrast sine-wave grating of two cycles per degree flashed on an oscilloscope field that was 12° in diameter. The observer carefully fixated a tiny light in the centre of the field and then pressed a button which presented a stationary grating for one 9 ms sweep. The luminance of the P4 white phosphor, as measured with a 1P22 phototube, fell to $1/e$ of the peak value in 1 ms. The field was dark between flashes. The grating was presented in a different, random position on each flash and could be vertical or horizontal. When vertical, it was viewed through a Wratten 30 magenta filter (or a Wratten 11 yellow-green filter) and when horizontal, through the yellow-green filter (or magenta filter). The mean luminance of the gratings through the filter was about 4 cd m^{-2}. The observer presented himself with a grating about every second for a total of 2,000 times. Every 50 flashes, the grating changed orientation and colour. After effects were built up to counter any initial colour bias that the observer reported while viewing black and white test gratings before adaptation.

All observers saw weak McCollough after effects of pink and green on a test pattern consisting of adjacent vertical and horizontal square-wave gratings of two cycles per degree. The pattern was viewed in fluorescent room light. The colours were more pronounced when the mean luminance was reduced considerably—from 100 to 0.1 cd m^{-2}.

Retinal image motion during adaptation cannot be completely ruled out in this experiment. It has been shown,[3] however, that movements greater than 1 min of arc are very unlikely during attempted fixation of a target which is exposed for less than 20 ms, and the retinal image is virtually stationary for exposures less than 10 ms. The second experiment eliminates even these tiny retinal image movements.

High contrast vertical and horizontal square-wave gratings of two cycles per degree were placed on a diffusing screen to form two fields 9° in diameter. These patterns were illuminated from the rear by Grass photo-stimulators rated at about 10^6 candles. Measurements showed that the flash lasted less than 60 μs. The lights did not appear bright, and the after image they produced lasted 1 or 2 s. Four observers viewed the vertical grating through the magenta filter and the horizontal grating through the yellow-green filter. To spread the adaptation evenly over the retina, four tiny lighted fixation points were placed on each grating, separated by phase angles of 90° with respect to the fundamental period of each grating. The observer triggered the flash about every 2 s while fixating one of these lights. Each fixation light was fixated equally often. Total adaptation was 200 flashes, with alternation between the vertical and horizontal grating every 20 flashes.

All observers reported seeing the McCollough effect, which was very evident. The colours were still seen 30 min after adaptation. This experiment shows that no retinal image motion is required to build up the McCollough effect. Our method of stabilising the image has the advantage over the contact lens method in that the image does not fade over time, and is thus a potent stimulus.

Retinal image motion is thus not required for the McCollough effect. Flashed gratings and gratings stabilised by the contact lens method might well cause movement mechanisms to fire and thus adapt. But the optimal stimulus for these mechanisms is a pattern moving in a specific direction. Thus, these experiments tell us nothing about movement mechanisms. It is possible, however, to generate McCollough effects selective to the direction of motion[4,5].

We thank Professor Karl Pribram and Professor Leo Ganz for support.

Mouse granulocyte precursors and multiple sclerosis

Sir,—Brown and Gajdusek[1] have recently reported failure to reproduce the suppression of peripheral blood granulocytes which was described[2] in mice following inoculation of material from patients with multiple sclerosis (MS).

We have also studied the effect on groups of ten weaning C57BL and CBA mice of intraperitoneal inoculation of 0.2 ml serum or brain extract (prepared as in ref. 2) from patients with MS. In agreement with Brown and Gajdusek, we found no differences in peripheral blood granulocyte levels up to 35 d after inoculation between mice inoculated with MS material, normal human serum, normal human brain or saline.

We used the agar culture technique for granulocyte-macrophage colonies[3] to enumerate granulocyte-macrophage precursor cells (colony-forming cells, CFC) in the marrow and spleen of inoculated mice, and in addition measured serum levels of the myelopoietic colony-stimulating (CS) factor[4]. Table 1 shows that 34 d after inoculation of MS brain extract into groups of 5 weanling C57BL mice there was no depression of granulopoietic potential compared with similar mice given normal brain extract or the medium used to prepare the extracts.

Table 1 Colony-forming cells after inoculation of normal and MS brain.

Material inoculated	CFC per femur ($\times 10^{-3}$)	CFC per 10^6 spleen leukocytes	Serum CS activity
Medium	42±17	25±15	10± 7
Normal brain	45±10	19± 8	8± 5
MS brain	61± 6	16± 7	15± 7

In this experiment the mice inoculated with MS brain actually showed a statistically significant increase in CFC per femur (but not in spleen which is usually a more sensitive indicator of changes in CFC populations[5]) compared with the mice given normal brain ($0.01 > P > 0.005$). No consistent differences in any of these parameters were found, however, between MS serum-inoculated mice and controls when tested in both C57BL and CBA strains.

We thank Dr J. H. D. Millar for sera from his MS patients, Dr Margaret Haire for specimens of normal and MS brain and the Medical Research Council for financial support.

book reviews

General relativity

Gravitation. By C. W. Misner, K. S. Thorne, and J. A. Wheeler. Pp. xxvi+1279. (Freeman: San Fransisco and Reading, December 1973.) £19.20 boards; £8.60 paper.

IN most cases it is probable that, if a scientific discovery had not been made by the person normally credited with it, it would have been made by someone else within a few years. There is one notable exception to this general rule: had Einstein died before 1916, the world would have probably had to wait another 50 years or so for the General Theory of Relativity. In fact Einstein was ahead of his time: after an initial burst of activity in the 1920s, there was very little work on the theory until about 1960. This neglect was caused partly by the belief that the theory was too complicated to allow predictions to be made in any but the simplest cases and partly by the fact that there did not seem any prospect of comparing the predictions with observation apart from the three famous Solar System tests which Einstein himself proposed.

During the period 1920–1960 the most exciting field of physics seemed to be quantum theory. The success of quantum electrodynamics led most physicists to feel that physics was Feynman diagrams. They distrusted general relativity because of its classical and geometric nature. This dislike of geometry is shown, for example, by the particle physicist Steven Weinberg in the introduction to his otherwise excellent book *Gravitation and Cosmology* (John Wiley, New York, 1972): ". . . too great an emphasis on geometry can only obscure the deep conncetions between gravitation and the rest of physics. . . . I believe that the geometrical approach has driven a wedge between general relativity and the theory of elementary particles".

But geometric insights have played an important part in many of the outstanding recent theoretical developments such as black holes, space–time singularities and gravitational radiation. The answer therefore seems to be not to free general relativity from geometry but to teach geometry to physicists brought up on the normal ideas of special relativity; that is, to teach them to regard space–time as a differentiable manifold and not as a flat vector space.

This is what Misner, Thorne and Wheeler have set out to do in their book. They have also endeavoured to give at least an introduction to those fields such as cosmology, gravitational waves, post-Newtonian effects in the Solar System, relativistic stars and black holes where general relativity is now, or is on the point of, making contact with the recent great advances in observation. All this combined with fairly large print and wide margins has produced a book weighing 6 pounds. Because this is too long for most postgraduate courses on general relativity, the authors have divided the material into two tracks which are indicated on the top corners of the pages. Track 1, which is designed to accompany a one-semester course, gives an impressionistic overview of the theory and its applications but to perform any calculation one would really need to master most of the Track 2 sections on the basic theory.

The style is typical of the Princeton school (Misner and Thorne are former students of Wheeler at Princeton). It is aimed more at giving the reader an intuitive feeling for the concepts involved than giving a mathematically rigorous axiomatic account. Important results and other material of interest are displayed in boxes. These are generally helpful though they sometimes rather interrupt the text. The book is also well provided with exercises ranging from easy to major research problems. These should be very helpful to students learning the subject.

The authors' research interests have obviously influenced the coverage of the book. There are very good sections on relativistic stars, black holes and experimental tests of relativity. On the other hand the section on cosmology is less detailed than that in Weinberg's book and suffers from the ideological insistence that the Universe is spatially closed. The section on gravitational waves gives a good account of the generation and detection of gravitational radiation but does not mention the work of Bondi, Sachs, Newman and Penrose on the 'peeling off' of the curvature tensor, the Bondi mass loss formula and the Bondi–Metzner–Sachs group. These and the comparative neglect of spinors are the main gaps in this book, which does not aim to describe in detail global results such as singularity theorems. Despite these omissions the book is a major landmark in the field and is likely to become the most widely used textbook and reference work on the subject. It is well printed and bound and the paperback version is cheap for a book of this size.

S. W. HAWKING

Radial parameters

Ligand-field Parameters. By M. Gerloch and R. C. Slade. Ppxii+235. (Cambridge University: London, August 1973.) £5; $15.

ALTHOUGH many books exist dealing with the theory of transition-metal complexes, this one is welcome, since it treats the subject in a novel way. Other texts approach ligand-field theory through symmetry and group theory, being concerned with aspects of the subject determined by molecular symmetry alone. This is a valid approach, but it is sometimes necessary to stress those parts of ligand-field theory where the molecular symmetry is less significant, and this is done here.

For all systems, group theory can only give information on quantities dependent upon the angular properties of wave functions. Radial properties appear only as proportionality constants. Furthermore, complexes of lower than cubic symmetry are less amenable to group-theoretical treatment, needing large numbers of parameters to describe the system.

In this book stress is laid on calculations of radial properties of regular octahedral and tetrahedral complexes, and the ligand-field parameters of non-cubic systems, thus rationalising pertinent data on such complexes. A summary of the role of symmetry in ligand-field theory is followed by a development of the crystal-field formalism, with a discussion of inter-electron repulsion parameters in cubic systems. Treatment of the radial parameters in various complexes of lower symmetry follows, with emphasis on trends in the parameters Cp and Dq.

The second half of the book seeks to interpret these radial parameters, covering calculations of $10Dq$, and use of the point charge model and semi-empirical molecular orbital methods (especially the angular overlap model) in rationalising trends in Dq and Cp. The final chapter contains a discussion of the Nephelauxetic effect.

The authors hope that the book will be useful to advanced undergraduates and young researchers; but although the treatment is sound and logical, the level of difficulty will probably prove to be too great for all save very few

undergraduates. Nevertheless, this is a very worthwhile contribution to a little-known aspect of an important area of chemical theory, which should be read by anyone with a serious interest in ligand-field theory. The book is well produced, with extremely few typographical errors.

G. DAVIDSON

Bioengineer's dreams

Phloem Translocation. By M. J. Canny. Pp. x+301. (Cambridge University: London, November 1973.) £7.50; $22.50.

THE question of how cells in phloem tissue, transport organic foodstuffs, viruses and other material from one end of a plant to the other, remains, tantalisingly, open. The nature of the movement and the force which drives it are still unknown. It is not even agreed about where in the pipelines any forces might be applied.

The reasons for this ripe state of affairs, and suggestions for improving it, are set out in this lively book by Martin J. Canny, Professor of Botany at Monash University.

It is now ten years since Professor Canny first proposed his own hypothesis or model to explain translocation. In the very first sentence of the preface he warns "This book is less a review of a field of plant physiology than a lengthy statement of a point of view about that field which, in the course of the argument involves the review of most of the work". His point of view is that translocation behaves like diffusion but is faster.

The angle of view in part one of the book ("The Experimental Facts", 211 pages) is wide. It gives an interesting, though sometimes closely argued account of the ups and downs of research into translocation; of the quantities translocated; of how the channel of movement was identified; of how patterns and rates of movement and gradients of concentration were studied; of the effects of temperature; of the nature of phloem exudates; of why functioning sieve elements are so difficult to examine and experiment with; and of what is known or controversial about their structure. In particular Professor Canny discusses very fully how the distribution of radioisotopic tracers and their concentration profiles in the transport channels are related to various patterns of flow proposed to occur through sieve tubes.

Part two (52 pages) is divided from part one by a group of 23 plates which contains 45 micrographs and photographs and two line drawings. These are well chosen to illustrate the text and beautifully reproduced.

In part two ("Towards a Mechanism") Professor Canny outlines briefly various mechanisms which have been proposed to explain translocation, and discusses their drawbacks. He then describes his own model as he first based it, in 1962, on hypothetical membranes round transcellular strands proposed by Dr R. Thaine. But he goes on to say that "The prime objection to the model is that the strand structures it uses seem not in fact to be there, nor any such tonoplast-type membranes as were originally imagined as separating them from the sap". Filaments, perhaps gathered together in bundles are all that appear in the electron microscope to warrant his highly sophisticated calculations, which have been criticised[1,2]. He now seems to suggest that "accelerated diffusion" might be caused by flow within (and of?) 250Å diameter tubular filaments, or within "small aggregates of them", and driven by "mechanicochemical means". I find flow through such filaments hard to believe; their resistance would surely be enormous[3]. Far-fetched models have an irritant value which provides much of the spark for research into translocation. But they can become an entanglement.

There are numerous useful tables, graphs, and drawings in the text. These provide essential information from many different sources for those who wish to make their own calculations about translocation, or try their hand at model building. The book has author and subject indexes, and a bibliography with more than 330 references. There are four short appendices.

I found this a stimulating and thought-provoking book. It should be read by anyone who wishes to know more about translocation. It demonstrates vividly how enthusiastic speculation stimulates the search for hard facts.

Bacterial envelopes

Bacterial Membranes and Walls. Edited by Loretta Leive. Pp. xv+495. (Microbiology Series.) (Dekker: New York, December 1973.) $38.

IT is fashionable in some quarters to pretend that the prokaryotes are a spent force as research models in biology. This collection of essays, all written by distinguished experts, might be read with great profit by those who promulgate or accept such views. Chapters such as those by Mindich on membranes, by Kaback on transport, by Luria on the colicins, by Tomasz on the uptake of DNA, by Pardee, Wu and Zusman on bacterial division and, despite its specialised title, certainly that by Ghuysen and Shockman on the biosynthesis of peptidoglycan (mucopeptide, murein) all embody principles of general biological importance. In particular the necessary confluence of those interested in DNA replication and nuclear segregation with those interested in cell envelopes, to tackle the fundamental biological problem of cell division, is illuminating.

Although the subject of cell division is mentioned in the title of only one chapter, five out of the total of nine essays deal at lesser or greater length with it. Indeed, it might have been profitable to put together a separate section of the book on this subject, taking and expanding the relevant sections from some of the other chapters. For example, the part of Ghuysen and Shockman's article called "Relationship to Morphogenesis and Division" could well have stood on its own in such a section. This section would also have included the stimulating but maverick article by Henning and Schwarz which points its didactic finger in almost the opposite direction to several of the other chapters, as well as the thoughtful and cautious article of Pardee with its epilogue. This is not to criticise either the book or the editor who has persuaded her distinguished soloists to perform with such crystal clarity of tone, even though she did not integrate them into a consonant orchestra, had this been desirable. It is rather meant to emphasise unsatisfied intellectual hunger stimulated from the brief remarks often made almost as asides by some of the authors.

The generality of the title is a little misleading since some considerable lacunae exist. There are, for example, no serious considerations of energy metabolism, despite the siting of important parts of the electron transport chain in membranes, no general or detailed ultrastructural studies, no biophysical studies, nothing on the export of macromolecules other than DNA, and no serious study of the transport of ions. The latter might have allowed the supporters of the chemiosmotic hypothesis a fair chance to reply to Dr Kaback's strictures on them. A brief mention of the L-forms of Gram-positive bacteria such as *B. subtilis* or *Streptococcus haemolyticus* might have given pause for thought to Henning and Schwarz in their considerations of the determinants of cell shape for, to adopt their style—if membrane, not mucopeptide formation, is alone shape determining how is it that unstable L-forms of Gram-positive bacteria totally without regular shape or division and without mucopeptide

rapidly revert to normally shaped bacteria which divide regularly when penicillin, a quite specific inhibitor of one step in mucopeptide biosynthesis is removed from their growth medium? But this book is already nearly 500 pages long and refers to some 1,400 papers.

References in the main text extend to 1972 and a short appendix at the end of the book improves this to 1973 for some chapters; considering the publication date of 1973 this is very satisfactory. It is beautifully produced, well indexed and singularly free of typographical errors. Both the editor and the publishers are to be congratulated. I hope that Dr Leive may be persuaded to edit a second companion volume in this microbiology series that will deal with the subjects perforce omitted from the present one. The book is to be recommended to all those directly interested in cell surfaces. Individual chapters could be suggested as supplementary reading to postgraduate and final year undergraduate students in biochemistry or microbiology, but the perusal of some more general books on bacteria and bacterial walls and membranes would be a necessary preliminary.

HOWARD J. ROGERS

Taxonomy of ferns

The Phylogeny and Classification of the Ferns. Edited by A. C. Jermy, J. A. Crabbe and B. A. Thomas. Pp. xiv+284. (Supplement No. 1 to the Botanical Journal of the Linnean Society, Vol. 67.) (Academic: New York and London, December 1973.) £9; $25.

THIS is a collection of papers based on those presented at a joint symposium held in 1972 by the Linnean Society and the British Pteridological Society. The original programme has been expanded by the addition of three further papers, extensive reference lists and, judging by the concentrated factual content of some papers, additional detailed data. New approaches and techniques of the last 20 years have revealed errors and inadequacies of past taxonomic treatments without firmly establishing alternative classifications. In several of these papers the view is expressed that conclusions are tentative and await further critical investigations. It was the organisers' stated intention therefore that the symposium should provide an opportunity to take stock of the present situation and provide stimulus and direction for further work. In this they will have at least partially succeeded, by inviting leading researchers to give authoritative and up-to-date assessments in their own area of interest. Supported by detailed data and extensive bibliographies these add up

Fiddle-head of soft shield-fern *Polystichum setiferum.*

to a useful reference book for the specialist pteridologist.

But by basing the programme on the choice of speakers rather than on themes within the overall broad scope of the title, the programme lacks cohesion, and few of the papers are linked together in any way. As, furthermore, there is no record of any discussion which may have been stimulated by the papers, the reader is left with the impression that the unique feature of a symposium has been lost.

On the dust jacket, there are the further claims that this is "a reference book to the cytology, anatomy, palynology, chemisty and gametophyte studies of the Filicopsida" and, making a curious distinction, "a valuable purchase for many botanists and plant physiologists". These claims, perhaps those of the publisher rather than the editors, are misleading. The cytology is largely restricted to chromosome numbers, the anatomy and palynology occurs mostly as scattered references in papers on particular genera or families, and the gametophyte study takes no account of the effects of environmental conditions on the development of diagnostic characters, even though protonema and prothallus development is known to be particularly sensitive to such factors as temperature, light intensity and light quality. Several of the diagnostic characters discussed in Atkinson's paper on the gametophyte as an indicator of family relationships can be induced or suppressed at will in, for example, *Dryopteris* species merely by changing the cultural conditions. Botanists (and plant physiologists!) not already familiar with the ferns will find the several essentially traditional treatments of groups such as the dennstaedtoids, cheilanthoids, Oleandraceae, Thelypteraceae, Polypodiaceae and Aspidiaceae of limited value. Several areas of more general interest such as serological and numerical taxonomy, breeding systems and apomixis, developmental physiology and the ecological significance of phylogenetic changes are omitted and the biosystematic approach is restricted to one paper by Lovis on the Aspleniaceae. Professor Manton comments that the production of phyletic schemes for the Filicopsida involves every discipline in botany, but this is not fully reflected in this book.

Those with historical interests will enjoy tracing fern classification systems back to the time when it was commonly believed that fern spores collected on Midsummer's Eve and placed in the shoe rendered the wearer invisible (see Shakespeare, W., Henry IV Part 1, act 2, scene 1, line 96 (1576)). Also, botanists with any interest in taxonomy will find some of the more general papers worth reading, particularly those by Swain *et al.* on the possibilities for biochemical systematics in ferns, by Van Cotthem on the classification of stomatal types, by Lovis on the biosystematic approach in the Aspleniaceae and by Wagner on future challenges in fern systematics. Walker's comprehensive survey of fern chromosome numbers and Wood's and the Tryons' use of spore surface structure revealed by scanning electron microscopy may also be of some use to those working with other groups of plants.

The limited success of this volume in achieving its secondary aims only emphasises the need for a general text on the biology of ferns to interest students in these fascinating plants and to re-educate those botanists whose impressions of the Pteridophytes are based on their past experience of unimaginative teaching within a narrowly systematic context.

A. F. DYER

Petrol and polar bears

Man, Nature and Ecology. By Keith Reid, J. A. Lauwerys, Joyce Joffe and Anthony Tucker. Pp. 418. (Aldus, Jupiter: London, March 1974.) £3.95.

THIS large and lavishly illustrated book aims to give a background in ecology to the layman with an interest in doom. It is too diffuse to have a profound impact—the four authors cover ecology, anthropology, rare animals, and problems of population and resources. The layman who remembers his school biology and reads the newspapers will know much of it already.

The parts I found most interesting were those on the problems inherent in the use of pesticides, antibiotics and the products of the green revolution.

The book ends with a list of suggestions for an ecologically virtuous life. Ironically one of the recommendations is to save paper by using both sides when writing letters: the authors don't mention how many trees had to be felled to produce their book.

GILLIAN MOORE

Classify knowledge

The Fabric of Knowledge: A Study of the Relations Between Ideas. By J. L. Jolley. Pp. 130. Duckworth: London, October 1973.) £2.95.

THIS monograph will be of interest to anyone concerned with the problems of organising scientific or technical documents. It is more specialised than the title suggests, being an examination of the use of integrative level theory for the organisation of concepts in scientific and technical subjects. There are three parts. The first recounts the development of Mr Jolley's ideas, the second supports them by means of set theory and the third is a brief summary of previous ideas applied in the organisation of knowledge.

The first section is the most satisfactory and least controversial. It should be read in conjunction with the account of similar work by the Classification Research Group in *Classification for a General Index Language*, by D. J. Foskett (Library Association, 1970). Despite the common starting point there seem to be considerable differences of detail in the two sets of ideas. The levels identified are not exactly the same and their method of use varies: the CRG uses them for organising entity concepts only, whereas Mr Jolley includes all concepts. His semantic types used within the levels also differ from the categories used by the CRG. Unfortunately a full comparison is not possible since Mr Jolley has not written at sufficient length to do himself justice. A lot more examples would have helped to clarify the sometimes eccentric terminology and definitions that in themselves are inadequate for complete understanding.

There is no reason to doubt the usefulness of Mr Jolley's analysis, since it is based on many years of work in indexing consultancy. Even the set theory may be useful, but the exposition here is difficult to understand. Whether it is really necessary is another matter: the CRG have managed without it. It could be that they have merely failed to make explicit the real theory underlying their work, but the experience with categories should be a warning against Mr Jolley's claim to objectivity. There are no generally accepted categories of reality, and their use in classification can only be judged pragmatically. The only way to be objective in the classification of ideas is to examine the nature of knowledge rather than the nature of some supposed objective reality.

There seems little ground for Mr Jolley's optimism about the extension of his theory beyond science and technology. Integrative level theory relates to natural objects and there is no obvious reason why it should provide a structure for philosophy, history, religion or the arts. It is sufficient that it has a use in science and Mr Jolley's work is welcome independent support for that of the CRG. Both his suggested pattern of ideas and the use of set theory are worthy of further research.

D. W. LANGRIDGE

Analysis

Elementary Real and Complex Analysis. By Georgi E. Shilov. Revised English edition translated and edited by Richard A. Silverman, Pp. xi+516. (Mathematical Analysis: Vol. 1). (MIT: Cambridge, Mass. and London, 1973.) $14.95.

THIS translation, by R. A. Silverman is, as usual, of high standard. The appearance of the book is good, the printing and accuracy so meticulous, that an error on page 223, where $f(x_0)+h$ should read $f(x_0+h)$, comes as a shock.

The book covers much of the analytical knowledge demanded of a mathematics graduate—real and complex numbers, vector functions, metric spaces, limits, convergence, elementary functions, the theorems of the calculus, Reimann (–Stieltjes) integrals, analytical function theory (for piecewise smooth curves) and improper integrals. The chapters on limits (using directions) and improper integrals are probably the most refreshing. Functions of several variables, measure and Lebesgue integration receive only passing reference.

The author's declared aim is an easier 'Dieudonné'; nevertheless mathematical sophistication, and hard thought about abstract ideas, are demanded of the reader particularly in the earlier chapters. This may prove a deterrent to weaker students, scientists and engineers for whom the book is also intended. There is a good collection of examples, some normally accorded theorem status, some difficult even with the hints of the appendix.

This is a scholarly book; carefully used it could provide a logical, integrated and economic presentation of basic work.

MARGARET JACKSON

Domestic life in Africa

Man and Woman among the Azande. Edited by E. E. Evans-Pritchard. Pp. 197. 8 plates. (Faber: London, February 1974.) £4.50.

SIR EDWARD EVANS-PRITCHARD died towards the end of 1973, and this is the last book to come from his pen. As such it is appropriate that in it he returns to the study of the Azande people of Central Africa, the group about whom he first wrote more than forty years ago and about whose thought he published his first major work.

This book is a collection of Zande texts, some taken down in the 1920s, some written more recently. Evans-Pritchard links these with brief comments of his own, and in a few places discusses and clarifies obscure passages. He is always careful to allow his Azande informants to speak for themselves and his editorial presence never prevents his reader from having to deal for himself with the complexities, contradictions and individualities of Zande thought and belief.

Evans-Pritchard was a great and respected social anthropologist, and it is probably due to his eminence that he was able to publish this book, for it is hard to believe that a commercial publisher would risk issuing a series of native observations about the problems and joys of domestic life if these were not supported by the name of such a famous author. But we must be thankful for that eminence, for it has made available a series of fascinating documents about the relations of men and women in a single exotic culture. Material such as this has rarely been published in book form before.

One of the main qualities of this book is that it shows the almost-raw material from which anthropologists build up their analyses and abstractions. Women quarrel, men complain, an informant recalls a story heard about a neighbour, an old man criticises the conduct of the young. All this is faithfully and simply recorded here and it is left to the reader to make what he can of it. In some places he would clearly benefit from additional information or guidance from the editor, but this is not provided. To get the full worth of the book it is therefore necessary to read some of Evans-Pritchard's other writings on the Azande; once this is done the mass of data about male/female relations can be used more profitably.

In the final count anthropologists depend on the quality of their informants. Evans-Pritchard, like Malinowski and others before him, always stressed the need to record information *verbatim;* only in that way, he argued, could a true appreciation of native

ideas be developed. Although the texts published here are but a small proportion of those collected during his working life, they reveal his skill at eliciting information and also his tact and sensitivity in allowing people to say or write what they wanted and not what would have best suited him. Rejecting analysis in his final works, he concentrated on making known the views of those he studied; the present book is typical of this approach. Though one might wish for more of his own views and ideas, the work as a whole provides a mass of interesting and valuable data. It is also a tribute to Evans-Pritchard's lifelong fascination with the lives and ideas of other men and his deep respect for these in all their variety.

M. D. McLeod

Molecular sieves

Zeolite Molecular Sieves: Structure, Chemistry and Use. By Donald W. Breck. Pp. ix+771. (Wiley: New York and London, January 1974.) £18.

THERE have been several shorter monographs on particular aspects of zeolite chemistry and technology, mostly in Russian, and also several bibliographies. In 1968, 1971 and 1973 volumes have appeared embodying the papers read in three international symposia on molecular sieve zeolites. But Dr Breck's monograph is the first comprehensive text reviewing all aspacts of zeolites except their catalytic properties. A second monograph is being considered which will cover this important area. I hope this will be completed in due course in the same comprehensive pattern.

In the book under review the introductory chapter is followed by chapters on structure, mineral zeolites, synthetic zeolites, physical properties, chemical properties and reactions, ion exchange, adsorption and finally manufacture and properties of commercial sieve zeolites. A feature of the book is the amount of illustrative material presented as tables. In the field of molecular sieves progress in the basic science and in applications is rapid ar the incorporation of the most recent developments presents considerable problems. The author has nevertheless been successful in providing coverage up to about 1972. The discussions of zeolite structure, crystal chemistry, synthesis, chemical reactions and properties are particularly interesting.

One may ask whether Dr Breck's classification of zeolites will appeal to mineralogists since it produces some strange bedfellows, for example analcime, phillipsite, paulingite and yugawaralite are all given as members of the same group. Cages of linked tetrahedra of $(Si,Al)O_4$ are referred to as α–, β–, γ– . . . cages. In my opinion these cavities would be better designated as 14-hedra, 26-hedra, and so on since this conveys partial information about their nature. The chapters on adsorption and ion exchange reproduce many isotherms, although usually without the experimental points which allow one to assess the accuracy and reversibility achieved in the original researches. In the introductory chapter a brief review is given of several other materials having molecular sieve properties such as Saran charcoals and alkali metal graphites, but one of the more important types, the alkylammonium-exchanged clay minerals, receives virtually no attention.

There are various printing errors but they do not usually result in ambiguity and are small matters in a book of this compass. The author is to be congratulated on completing a monograph which will, despite its price, be indispensible to all those interested in molecular sieve science and technology, and which should become the first standard work on this subject. The format is attractive, clear and easy to read.

R. M. Barrer

Plant components

Phytochemical Methods: A Guide to Modern Techniques of Plant Analysis. By J. B. Harborne. Pp. x+278. (Chapman and Hall: London; Halsted Press, a division of Wiley: New York, 1973.) £4.80.

THE aim of the author is to provide undergraduate students and research workers with a series of proven methods of phytochemical analysis in a single volume at a reasonable cost. After a brief survey of general extraction, analytical and identification procedures, specific methods for each major class of organic constituent found in plants are considered. Much of the book (98 pages) is concerned with a comprehensive discourse of methods used for the analysis of phenolic compounds and terpenoids. The coverage of the organic acids, lipids and related compounds, nitrogen compounds and sugars, though not as extensive as the phenolics, is adequate. The macromolecules including the nucleic acids, proteins and polysaccharides are deliberately considered in less detail owing to space limitations and widespread coverage in other texts. It is unfortunate that more space could not have been allocated to this important area of research.

Each chapter contains sections on the chemistry, distribution and recommended qualitative and quantitative procedures for each component which have widespread application in research laboratories. Sufficient detail has been included to enable the inexperienced worker to attempt the methods and the practical experiments in each section should help the student gain experience with the procedures. The carefully selected references at the end of each section should aid the worker to quickly develop or modify the techniques to suit his own requirements. The author assimilates the rapidly expanding and difficult area of phytochemical methods into a well written and informative text which should be welcomed by both students and researchers.

G. Norton

Flies and humans

Flies and Disease. Vol 2: Biology and Disease Transmission. Bernard Greenberg. Pp. x+447. (Princeton University. Princeton, September 1973.) £4.50.

THIS second volume of *Flies and Disease* complements volume 1 which appeared in 1971.

The introductory chapter provides an historical survey of the association of flies with man throughout recorded history. This is one of the most fascinating chapters in the book, documenting both early myths and observations on the natural history of flies. A slip of paper in the mouth of a mummy "The maggots will not turn to flies within you" illustrates the Egyptians' appreciation of insect metamorphosis many centuries ago.

The second chapter deals with the life history and habits of ten common genera of synanthropic flies. There are several important omissions here (for instance, *Musca domestica*), justified on the grounds of treatment elsewhere in the literature, and the information given is occasionally rather disjointed because of the variety of interests of the original authors. The chapter ends with a discussion of the estimation of fly density (simple Lincoln index only) and dispersal: table 3 is a useful summary of the dispersal of more than 40 fly species.

Chapter 3 investigates flies as hosts of a variety of micro-organisms and describes the changes which take place in the gut fauna during metamorphosis. Many larval microbes are lost during pupation and emerging adults may even be sterile. The relevance of this to the vectorial capacity of saprophagous flies is examined.

The two final chapters discuss flies as disseminators of more than 50 human and animal diseases. In the absence of definitive parasite stages in the insect hosts, the importance of flies relative to other transmission pathways is often based on circumstancial evidence alone; for example a correlation of increased numbers of

disease cases with seasonal plagues of flies. Professor Greenberg deals with these examples in an open-minded way, admitting where the evidence is slight and emphasising where new research efforts should be directed.

The book has an extensive bibliography, including many early works. The style of the illustrations is very variable and occasionally disappointing, but the volume as a whole will be a useful source of information and reference for public health workers, epidemiologists and entomologists alike.

DAVID ROGERS

Image of a scientist

Science as a Career Choice: Theoretical and Empirical Studies. Edited by Bernice T. Eiduson and Linda Beckman. Pp. xv+735. (Russell Sage Foundation: New York, 1973.) £10.40.

WHY I feel able to embark upon the formidable task of reviewing this work, which is a vast book largely concerned with psychological theory and studies of the process of socialisation, is that the choice of career is a crucial factor in economic analysis of the way in which the labour market works. It is therefore necessary to review as much of the evidence as possible presented by a variety of disciplines in order to see what it is that drives people to make one choice rather than another.

This interesting study is a collection of papers concerned with the mechanisms of career choice and the way that people drift into the physical and other sciences, and what sort of people they are. Scientists apparently (page 670)

> "lead quite, unpretentious, even-tenored, rather steady lives. They come home regularly for dinner, and spend the time before and after dinner with their children and wives; pursue their hobbies systematically; and more often than not, spend the evenings reading journals, novels, magazines, or watching television. Most live on a fairly modest scale and do not spend much for theatres or entertainment... despite the fact that their home lives are interesting and varied, one gets the impression that these do not reflect their most exciting selves. For one thing, the interviews reveal that the scientists are not able to give the most significant parts of themselves to home and family."

To an outsider, this is an extraordinarily perceptive description of the home lives of many scientists, and also suggests the degree of secretiveness and obsession with work which has seemed so often a characteristic of scientists with whom one has been thrown into contact. Terman seems to have shown that scientists chose a subject early, and that their early socialisation tended to isolate them by making them feel different from other children. According to other studies, those people who are going to take up science develop an image of a scientist which tends to become self-confirming: the scientist is committed, studious, collaborative, concerned primarily with science; and that this perpetuation of a self-image which is assisted by highly developed social structures therefore tends to make the scientific community a fairly close one which is self-recruiting. This would also suggest that it was a social system which tended to push other people out, particularly people who developed an interest in science later in life, or people who had unusual social characteristics.

This description of the physical scientists contrasts markedly with those who call themselves social scientists. There seems to be some evidence that physical scientists come from individualistic and rather cold families (page 17) with high intellectual motivation. There is also, it seems, some evidence that the classic image of the pure scientific researcher clashes somewhat severely with most scientists' actual experience of their work. Interestingly enough, there are astonishingly few female or black scientists in the American studies which are cited here, and therefore the scientific community in the United States may be described as predominantly white and male, thus presumably reinforcing the tendencies towards a self-perpetuating community which have just been outlined.

The editors point out that the evidence, although very bulky, is in fact sketchy and derived from a great many partial studies of certain aspects of the problem, and therefore the very brief allusion which has been given here to some aspects of the work must be treated with great caution. Nevertheles, it does illustrate the probability that career choices between becoming a non-scientist or a scientist, and within the sciences, are largely affected by what economists would regard as irrational motivations, and also implies to the outsider that there must be a considerable number of people inside science who have been attracted into it by their own fantasies and who are now living in a world in which their fantasies clash rather sharply with reality. This may not be an untypical situation, but presumably it must be particularly disillusioning inside a closed profession like science, where so much of the original choice of career has depended upon high hopes and aspirations.

JOHN VAIZEY

Lymphocyte dogma

T and B Lymphocytes. By M. F. Greaves, J. J. T. Owen and M. C. Raff. Pp. vii+316. (Excerpta Medica: Amsterdam; American Elsevier: New York, 1973.) £14.08.

HERE is a book to fill with joy the hearts of cellular immunologists. So many pages devoted to T and B lymphocytes and only 4p per page.

T and B lymphocytes, by which is meant lymphocytes derived from the thymus and lymphocytes derived from the bursal equivalent (whatever that is) respectively, have after a shaky start in the 1960s become all the rage at the beginning of the 1970s. The present book represents a sort of consummation of this rage.

The history of the notion of two modalities of lymphocytes is given *pari passu* with a general account of the relationship between the immune response and the lymphoid system. The variously described properties of T and B lymphocytes are adequately documented. The authors go in detail into the mysteries of T and B lymphocyte participation in immunological responses and as a rousing finale consider the clinical applications of T and B lymphocyte theory. There is an appendix said to deal with the manipulation of T and B cell responses and an extensive and up-to-date reference list. The index could be more comprehensive but the diagrams and illustrations are good.

It seems on compelling evidence that the various chapters of the book have been written each by a different author but the blend overall is eminently readable and not markedly reiterative. Further, there are many and healthy instances in which ignorance in relation to particular points of fact is stressed. The book is heavily orientated towards work on mice but in this respect it reflects the activities of the bulk of contemporary cellular immunologists.

Greaves, Owen and Raff are to be congratulated on a timely and carefully prepared book which, despite its price, will be a boon to teachers of immunology. The only danger in it is that it will be seen as an orthodox statement of fact rather than what it is, the enunciation of a most interesting working hypothesis.

A. J. S. DAVIES

Erratum

IN the illustration "Butterfly Collection" (**248**, 289; 1974) the habitats of *Idea hypermnestra* and *Marpesia chiron* should have been given as Malaysia and South America respectively.

obituary

N. A. Mackintosh

NEIL ALISON MACKINTOSH, CBE, DSc, ARCS, the distinguished biological oceanographer and authority on the ecology and populations of whales, died on April 9, at the age of 73. He was educated at Westminster School and Imperial College where he very soon showed an aptitude for zoological research; in less than two years after graduation he had completed two papers on such widely different subjects as the chondrocranium of fish (*Proc. zool. Soc.*, 1923) and the crystalline style of gastropods (*Q. Jl. microsc. Sci.*, 1925).

He was in at the very beginning of that great enterprise, the Discovery Investigations of the Antarctic seas, when in 1924 he led the advance party to establish and take charge of the Marine Laboratory for the study of whales at South Georgia. Later he took part in three major expeditions of the *Discovery II*, being leader of two circumpolar voyages and bringing back a wealth of information on the plankton and hydrography of the Southern Ocean. In 1936 he had succeeded Dr Stanley Kemp as Director of Research until 1949 when the Investigations were merged with the new National Institute of Oceanography, of which he became deputy director, and since 1936 he had edited the long series of *'Discovery' Rep.* to which he made many outstanding contributions including one to be published in the thirty-sixth volume only four months before he died. In 1961 he established and directed the Institute's whale research unit at the British Museum (Natural History). He took a prominent part in the International Whaling Commission, being chairman

of its Scientific Committee. His contributions to knowledge lay in two main fields: the biology and conservation of whales, and the oceanic macroplankton.

It was at the laboratory adjacent to the whaling station at Grytviken, South Georgia, and on visits to stations on the African coast during the Antarctic winters (when the whales go north) that Mackintosh and Dr J. F. G. Wheeler, working together, amassed the enormous amount of information, based on the examination of nearly 1,700 whales, for their important monograph on the Southern Blue and Fin whales (*'Discovery' Rep.*, **1**, 1929). This and a number of later reports by Mackintosh laid the foundations of most of the current knowledge of the economically important species.

At Grytviken, Mackintosh and Wheeler discovered the remarkable rates of growth of the Blue and Fin whales. Mackintosh's book *The Stocks of Whales* (1965) is an important contribution to a study of their populations and conservation prospects based on a number of his earlier investigations, particularly his "Southern stocks of whalebone whales" in *'Discovery' Rep.*, **22**, 1942.

He made an extensive oceanographic survey of the macroplankton of the Atlantic sector of the Antarctic seas and was the discoverer of a remarkable seasonal vertical migration of many of the species whereby they are carried northwards in the surface waters during the summer months and then sink in winter to be returned towards the pole by a lower south-bound current ready to arise again the following spring. More recently, from the vast collections of earlier years, he renewed the investigation of the krill, producing two important studies: one relating the life cycle to ice and water conditions (*'Discovery' Rep.*, **36**, 1972) and another on the circumpolar distribution of the post-larval stages (*'Discovery' Rep.*, 1973).

Neil Mackintosh was one of the kindest and most modest of men, intensely disliking anything in the way of publicity. Indeed, his retiring nature was perhaps a fault, for because of it, so few in the outside world realised the greatness of the Discovery Investigations' achievements, including, of course, his own. He was awarded the Polar Medal in 1942 and the Patron's Medal of the Royal Geographical Society in 1954.

Announcements

Appointments

Henryk M. Wisniewski has been appointed Director of the Medical Research Council's Demyelinating Diseases Unit at Newcastle upon Tyne.

Gwynne James Morgan has been appointed Professor of Theoretical Physics at the University of Leeds.

C. D. Green, A. P. Halestrap, D. I. A. MacLeod, J. R. Rhodes, Barbara M. F. Pearse, Elizabeth C. Cartwright and **C. R. Hiley** have been elected to Beit Memorial Junior Fellowships for Medical Research.

David Anthony King has been appointed to the Brunner Chair of Computer Studies at the University of Liverpool.

Geoffrey Bernard Cook has been appointed to the Chair of Computer Studies at the University of Hull.

D. P. J. Browning, Violet R. Cane, K. M. Clayton and **T. W. Goodwin** have been appointed to the University Grants Committee.

A. S. V. Burgen, J. N. Walton, S. Cohen and **D. C. Phillips** have been appointed to the Medical Research Council.

Awards

Denys H. Wilkinson has been awarded the American Physical Society's 1974 **Tom W. Bonner Prize** in Nuclear Physics.

The **Linnean Gold Medal** of the Linnean Society of London has been awarded to **E. H. W. Hennig** and **J. Braun-Blanquet.** The **H. H. Bloomer Award** has been presented to **A. F. Millidge** and **George H. Locket.**

Corrigendum

IN the article "Heavy ion transfer reactions in nuclear astrophysical processes" by T. W. Conlon (*Nature*, **247**, 268; 1974) the third paragraph from the end should read as follows. "A study of the α-transfer reaction $^{12}C(^{16}O,^{20}Ne)^{8}Be$ at energies in the region of the Coulomb barrier has been made possible by the development of a particle identification system based on position-sensitive counters mounted in the focal plane of a Bueschner spectograph. Preliminary results indicate that significant amounts of ^{20}Ne are produced with respect to ^{24}Mg, which results from the principal compound nucleus channel (Table 2)."

In the same article, the following corrections should have been made; para. 1, line 12 should read "corresponds to the transfer of an α particle, . . ." para. 10, line 5, "available for later evolutionary . . ." and the last column in Table 1 should be "*Q* opitum (MeV) corresponding to (E min to E max)."

International meetings

July 8–10, **15th Annual Meeting of the Society for Economic Botany** (Mr Bruce Alderman, Kellogg Centre, MSU, S. Harrison Road, East Lansing, Michigan 48824).

July 23–24, **550th Meeting of the Biochemical Society** (The Meeting Officer, The Biochemical Society, 7 Warwick Court, Holborn, London WC1R 5DP).

August 5–9, **7th Semi-Annual Short Course on Laser Safety** (R. James Rockwell, Jr., Laser Safety Course, Conmed, 114 Medical College, Cincinnati, Ohio 45219).

August 26–28, **Pacific Slope Biochemical Conference** (Calvin S. McLaughlin, Secretary-Treasurer, Department of Molecular Biology and Biochemistry, University College Irvine, Irvine, California 92664).

APPOINTMENTS VACANT

THE UNIVERSITY OF MANCHESTER
LIBRARIAN/CURATOR

Applications are invited for the post of Librarian/Curator in the Department of Geology. The person appointed will look after maps and books in the departmental library, and will also be responsible for the care of the Department's teaching and research collection of rocks, minerals and fossils. Candidates should have, or expect to have shortly, a degree in geology, or a combined degree including geology. Initial appointment within the Graduate Assistant salary range p.a. £1,569 to £1,791 (under review). F.S.S.U. Further particulars and application form (returnable by June 28) from the Registrar, The University, Manchester M13 9PL. Quote ref: 116/74/N. (2351)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF BIOLOGY

Applications are invited for the post of lecturer in the Department of Biology. Candidates should have an appropriate Honours Degree and a research interest preferably in cytogenetics or cell culture. Opportunities exist for collaboration with the work of the Clinical Geneticist in the Faculty of Medicine. The lecturer will be expected to play a major part in teaching genetics to undergraduates in the Department of Biology and the Faculty of Medicine. Salary scale: £2,118 to £4,896. F.S.S.U. Initial salary will depend on qualifications and experience. Further particulars may be obtained from the Deputy Secretary's Section (Ext. 2400), The University, Southampton SO9 5NH to whom applications (seven copies from United Kingdom applicants) should be sent not later than July 12, 1974. Please quote reference number Na236/A. (2378)

STANDARDS LABORATORY FOR SEROLOGICAL REAGENTS

Technician AIMLT (Bacteriology or Virology) or HNC in Medical Laboratory Sciences (Microbiology) required to work with Australia Antigen. Graduates may apply for this position.

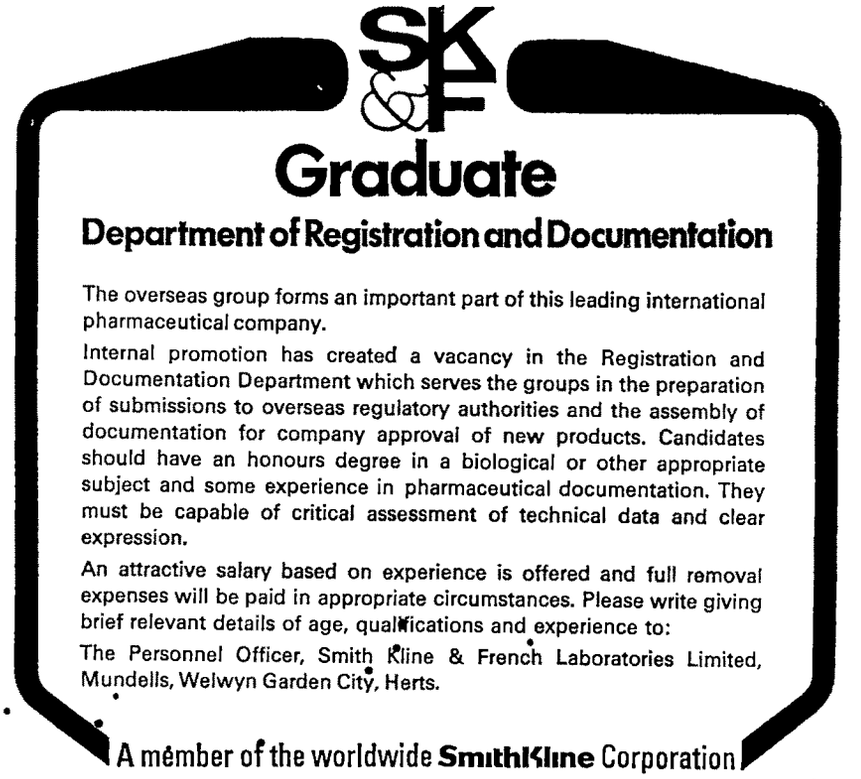
Written applications with full details of age, experience and qualifications to the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (2392)

DUNSTAFFNAGE MARINE RESEARCH LABORATORY
OBAN, ARGYLL
SCIENTIFIC OFFICER

Applications are invited for the post of Scientific Officer to join a multidisciplinary group working on the breakdown of cellulose in marine sediments. The applicant would be expected to have a University degree or equivalent in Microbiology or related science. Post would be for initial period of two years; starting annual salary around £1,435.

Application forms can be obtained from the Director, Dunstaffnage Marine Research Laboratory, P.O. Box 3, Oban, Argyll PA34 4AD. (2387)

Reckitt & Colman
PHARMACEUTICAL DIVISION



Section Leader Microbiologist

QUALITY CONTROL

To lead a small, expanding team in the Bacteriological Laboratories involved in Microbiological quality control of the company's products. The successful candidate, who will report to the Chief Bacteriologist, will have at least HNC in Medical Laboratory Science or Applied Biology with relevant experience of routine microbiological control within the pharmaceutical or food and dairy industry. The ability to effectively supervise junior staff and to present results and reports in a clear and concise manner is essential. Starting salary will be within the range of £1,600 to £2,300 according to experience and qualifications.

The Pharmaceutical Division is expanding and opportunities for promotion are good. The Company offers four weeks annual holiday, good sports, social and welfare facilities and operates a bonus and pension scheme.

Please write with details of career to date, qualifications, etc. Alternatively telephone or write to request an application form to: **Mrs. P. A. Haynes, Staff Personnel Officer, Reckitt & Colman, Dansom Lane, Hull HU8 7DS.** (2544)

Graduate

Department of Registration and Documentation

The overseas group forms an important part of this leading international pharmaceutical company.

Internal promotion has created a vacancy in the Registration and Documentation Department which serves the groups in the preparation of submissions to overseas regulatory authorities and the assembly of documentation for company approval of new products. Candidates should have an honours degree in a biological or other appropriate subject and some experience in pharmaceutical documentation. They must be capable of critical assessment of technical data and clear expression.

An attractive salary based on experience is offered and full removal expenses will be paid in appropriate circumstances. Please write giving brief relevant details of age, qualifications and experience to:

The Personnel Officer, Smith Kline & French Laboratories Limited, Mundells, Welwyn Garden City, Herts.

A member of the worldwide **SmithKline** Corporation

(2539)

HEDGES AND BUTLER LTD.

Microbiologist

We are seeking a graduate Microbiologist to provide an efficient and complete mycological and bacteriological service to our Central Laboratory situated in our major production and packing complex at Bromley-by-Bow.

Although primarily a quality control function some applied research together with development of existing methods is envisaged. Self motivation and initiative are essential.

Applicants, male or female, will probably be in the age bracket 24-35 and will possibly already have had three or more years industrial experience. An Upper Second in Microbiology is the minimum degree level required and a higher degree would be advantageous.

This position offers an excellent opportunity to a person interested in furthering management skills whilst retaining contact with the latest technical developments in this field.

Good conditions of employment and other benefits including free life assurance and a contributory pension scheme will apply. A good salary will be negotiated which will reflect the importance of this appointment.

Please write with a detailed curriculum vitae, including details of age, experience and current salary to: Miss J. Long, Personnel Department, Hedges and Butler Limited, Three Mill Lane, Bromley-by-Bow, E.3 or alternatively telephone 01-980 7133 for an application form.

(2400)

RESEARCH IN MUSCLE DISEASE

Applications from honours graduates in biochemistry or a related discipline are invited for the post of Research Assistant in continuing studies of muscle metabolism in health and disease.

The successful applicant will be expected to register for the degree of Ph.D. at the University of Glasgow. The post carries N.H.S. grading, with appropriate superannuation and salary (£1,797 to £2,259) from October 1, 1974.

Applications naming two referees should be sent as soon as possible to Dr W. H. S. Thomson, Research Laboratory, Knightswood Hospital, Glasgow G13 2XG. (2428)

THE BRITISH COUNCIL

invites applications for the following post:

TECHNICAL LIBRARY ADVISER (INDONESIA)

GEOLOGICAL SURVEY OF INDONESIA LIBRARY, BANDUNG

Candidates must have mature experience in scientific librarianship and information science including general administration, and have professional qualifications of the Library Association.

Salary: £3,541 to £4,710 p.a.

Benefits: Free furnished accommodation; overseas and education allowances; terminal grant. 74 BO 37

Two year contract, usually renewable for a further period. Return fares are paid. Local contracts are guaranteed by the British Council.

Please write, quoting the reference number, for further details and an application form to The British Council (Appointments), 29 Bressenden Place, London SWIE 5DD. (2472)

UNIVERSITY COLLEGE, CARDIFF

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANT

and a Graduate Research Assistant to work on the "Rôle of certain enzymes in the development of lung diseases, induced by the inhalation of various types of dust".

The work is supported by a grant for 3 years from the M.R.C. starting October 1, 1974. Postdoctoral salary—£1,929 rising to £2,223 p.a. (under review). Graduate Assistant salary—£1,416 rising to £1,524 p.a. (under review).

Applicants for the Postdoctoral position should have some experience in protein chemistry and/or enzymology. Applicants for the Graduate post should possess a B.Sc. or similar qualification and have a good knowledge of basic biochemical techniques.

Applications including a curriculum vitae and the names and addresses of 2 referees should be sent to: The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Please quote ref. 0591. (2471)

LISTER INSTITUTE OF PREVENTIVE MEDICINE

Elstree, Hertfordshire

BLOOD PRODUCTS LABORATORY

Recent graduate in microbiology required for control testing of human blood products and to assist in development work.

Please apply stating qualifications, age and experience to The Secretary, Lister Institute of Preventive Medicine, Elstree, Hertfordshire, from whom further particulars can be obtained. (2374)

CITY OF LONDON POLYTECHNIC

SIR JOHN CASS SCHOOL OF SCIENCE AND TECHNOLOGY

READER IN CELL PHYSIOLOGY

Applications are sought from highly qualified persons for the post of Reader in the Department of Biological Sciences.

In addition to providing a wide range of undergraduate and postgraduate teaching and research the School is a nationally recognised centre for biomedical studies. The successful candidate will be expected to initiate and develop lines of research in cell physiology preferably with some relationship to health or environment—and will also be expected to play a significant rôle in the development of new course work in the biological sciences particularly in relation to undergraduate programmes within the B.A./B.Sc. (C.N.A.A.) Modular Degree Scheme, the Higher National Certificate in Medical Laboratory Science and the Diploma in Medical Technology.

The post is tenable from September 1, 1974 or as soon as possible thereafter.

Salary scale—4 consecutive points within the scale £4,380 to £4,824 (London Weighting Allowance of £118).

Full details and an application form, may be obtained from the Assistant Secretary, City of London Polytechnic, 117/119 Houndsditch, London, E.C.3. (2515)

ANIMAL BREEDER
UNIVERSITY OF GUELPH

Ph.D. in Animal Breeding with background in statistical genetics. Experienced in data analyses and interested in working with animal industry breeding developments. Responsible for developing a research programme and teaching undergraduate and graduate students. Appointment at Assistant Professor level. Applications accepted to August 31, 1974.

Apply to: W. D. Morrison, Professor and Chairman, Department of Animal & Poultry Science, Ontario Agricultural College, University of Guelph, Guelph, Ontario, Canada N1G 2W1. (2492)

UNIVERSITY OF DURHAM
DEPARTMENT OF BOTANY

Applications are invited for studentships tenable from October 1, 1974, from chemists, biochemists or botanists, to work on the biochemistry of grain legume improvement. Successful candidates may register for a higher degree.

Applications to Professor D. Boulter, Department of Botany, Science Laboratories, South Road, Durham DH1 3LE. (2516)

CONSERVATION OFFICER

required by Dorset Naturalists' Trust. Degree in Biology/Ecology, plus conservation training or experience. Ability work with amateurs. Minimum starting salary £1,600 p.a. Contributory pension scheme. Full details from Hon. Sec., Dorset Naturalists' Trust, 58 Pearce Avenue, Poole, Dorset. (2510)

MARINE PHYSIOLOGIST

The Rosenstiel School of Marine and Atmospheric Science has an opening for a whole animal physiologist with at least a secondary interest in environmental physiology, beginning as early as January, 1975. Responsibilities will include teaching a graduate level course on the physiology of marine animals. Appointment will be at a rank and salary commensurate with experience and qualifications. Applicants must have completed the Ph.D. degree. Send curriculum vitae and names of five referees to Dr Barrie F. Taylor, Chairman of Search Committee, University of Miami, R.S.M.A.S., 4600 Rickenbacker Causeway, Miami, Florida 33149. Applications close on August 31, 1974. (2509)

DIRECTOR

The Jackson Laboratory invites applications for the position of Director of the Laboratory, which will become open on October 1, 1975. Qualified applicants are invited to submit a curriculum vitae and summary of experience to one of the following:

Dr James D. Ebert, Chairman, Search Committee, Marine Biological Laboratory, Woods Hole, Massachusetts 02543;

Dr James F. Crow, Member, Search Committee, Department of Medical Genetics, University of Wisconsin, Madison, Wisconsin 53706;

Dr Douglas L. Coleman, Secretary, Search Committee, The Jackson Laboratory, Bar Harbor, Maine 04609.

AN EQUAL OPPORTUNITY EMPLOYER. (2508)

SUB-EDITORS

BUTTERWORTH'S have two vacancies in their Scientific Publishing department. Previous experience of sub-editing manuscripts and all aspects of book publishing is essential. A degree in chemistry or the life sciences is necessary.

The offices are situated in pleasant rural surroundings at Borough Green, near Sevenoaks, and company transport is available from certain surrounding districts. The minimum salary for a qualified sub-editor is £2,405 p.a. and new rates are at present under negotiation.

Please write, giving details of age, experience and qualifications to:

Mrs D. Lulham,
Butterworth & Co. (Publishers) Ltd.,
88 Kingsway,
London WC2B 6AB. (2511)

The University of Birmingham

Wellcome

THE WELLCOME FOUNDATION LIMITED

Structure, Physiology and Biochemistry of Insect Neuromuscular Junctions

Applications are invited for a CASE postgraduate studentship in the above field of work.

The student will work primarily in the Department of Zoology and Comparative Physiology at Birmingham University with some time spent in the Unit of Arthropod Physiology at the Wellcome Research Laboratories, Berkhamsted Hill, where biochemical aspects of work in this field are currently in progress.

The Studentship commences on 1st October, 1974 and is tenable for 3 years. The current value of the Studentship is £695 per annum.

Further details may be obtained from the Academic Supervisor:

Dr. M. P. Osborne,
Dept. of Zoology & Comparative Physiology,
University of Birmingham,
Edgbaston, BIRMINGHAM.

(2362)

SK&F

Technical Information in a Sales Environment

This post provides the opportunity for someone with a background in technical information work to move closer to the marketing sphere.

As a member of a team dealing with our full range of products, the prime responsibility will be for the provision of a full technical input to the sales function for our range of biological products. This will involve maintenance of product information dossiers, preparation of product licence applications and assistance with preparation of promotional material and technical training. There will also be a responsibility to represent the company's interest at conferences and seminars, and for the co-ordination of activities relating to the introduction of new products.

The Company, SmithKline Animal Health, is concerned with the development, manufacture and sale of veterinary medical products and feed additives on a worldwide basis.

Applicants should be in their mid to late twenties and will have already gained experience of technical support or information work in the health-care field. A biological science degree and knowledge of a European language is desirable. Salary will depend on the immediate contribution which the candidate is capable of making and an excellent range of benefits apply.

Please write giving brief career details to Mr. A. Maltby, SmithKline and French Laboratories Limited, Mundells, Welwyn Garden City, Herts.

(2567)

A member of the worldwide **SmithKline** Corporation

Tropical Products Institute, London

Food Scientist

■ Develop new food uses of tropical produce ■ Biochemical/chemical research relevant to food processing ■ Opportunity to work independently overseas.
☐ 1st/2nd hons degree in Biochemistry, Chemistry ☐ Some relevant experience in food industry desirable ☐ Age under 27 ☐ Appointment as Scientific Officer (£1663–£2557, under review, plus threshold payment) ☐ Ref: SA/24/JD.
☐ Application forms (for return by 16 July 1974) from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB

Tropical Products Institute, Slough, Bucks

Entomologist

■ Research on biological problems relating to insect infestation of stored produce ■ Investigation of integrated control methods ■ Assist with training technologists from developing countries ■ Opportunity to work overseas.
☐ Degree in Zoology or Biology ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2221–£2854) or Scientific Officer (£1435–£2329) ☐ Additional threshold payments ☐ Salaries under review ☐ Ref: SA/23/JD.
☐ Application forms (for return by 16 July 1974) from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.

Department of Health and Social Security London

Information Scientist

■ In Medical Division ■ To compile information on chemical contamination of food including additives, colouring, insecticides and pesticides, and on environmental health problems ■ Help develop data storage and retrieval system.
☐ Degree or equivalent in chemical or biological subject ☐ Age under 27 ☐ Appointment as Scientific Officer (£1663–£2557, under review, plus threshold payment) ☐ Ref: SB/2/K.
☐ Application forms (for return by 15 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, telephone Basingstoke 29222 ext. 500 or 01-839 1992 (24 hour answering service).

Ministry of Agriculture, Fisheries and Food Royal Botanic Gardens, Kew

Botanist

■ In Jodrell Laboratory ■ Supervise assistants carrying out anatomical research ■ Undertake, after initial training, the identification of plant fragments and organs ■ Develop new techniques ■ Use optical and scanning electron microscopes ■ Give technical advice to visiting research workers.
☐ Degree in Botany ☐ Interest in literature on natural history and geography ☐ Age under 30 ☐ Appointment as Higher Scientific Officer (£2331–£2964) or Scientific Officer (£1545–£2439) ☐ Additional threshold payments ☐ Salaries under review ☐ Ref: SB/10/AH.
☐ Application forms (for return by 15 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Ministry of Agriculture, Fisheries and Food Plant Pathology Laboratory, Harpenden

Plant Scientist

■ Responsible for technical and scientific aspects of plant health in Crop Certification Schemes to produce improved propagation material ■ Liaise with UK official bodies and growers' organisations ■ Travel involved ■ Advise on administration of plant disease legislation ■ Investigate mycological problems.
☐ 1st/2nd hons degree or equivalent in Plant or Agricultural Science, or related subject ☐ Knowledge of plant pathology and ability to organise essential ☐ Knowledge of Agriculture desirable ☐ At least 2 years post-graduate experience ☐ Age normally under 32 ☐ Appointment as Senior Scientific Officer (£2798–£3895) or Higher Scientific Officer (£2221–£2854) ☐ Additional threshold payments ☐ Salaries under review ☐ Ref: SB/3/AG.
☐ Application forms (to be returned by 12 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke 29222, ext. 500 or London 01-839 1992 (24 hour answering service).

Science group
CIVIL SERVICE

(2523)

TOXICOLOGISTS

Veterinary Graduates, preferably with experience, required for Short and Long Term Toxicological Studies of compounds of potential therapeutic importance. Excellent opportunities for advancement in modern, well-equipped laboratories and Animal House. Pension and Assurance Scheme. Application forms from the Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB.

(2490)

BIRKBECK COLLEGE
(UNIVERSITY OF LONDON)
DEPARTMENT OF ZOOLOGY
M.Sc. DEGREES FOR PART-TIME STUDENTS
IN
ENTOMOLOGY
AND IN
COMPARATIVE PHYSIOLOGY

Each Course extends over a period of two calendar years and involves attendance on three evenings each week during term. Examination is by written papers and course assessment.

Full details may be obtained from The Secretary, Department of Zoology, Birkbeck College, Malet Street, London WC1E 7HX, to whom application should be addressed. (2507)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(UNIVERSITY OF LONDON)
COURTAULD INSTITUTE OF BIOCHEMISTRY
RESEARCH ASSISTANT

Applications are invited from Honours Graduates in Biochemistry for the above post for work on lipid metabolism in the nervous system in relation to Multiple Sclerosis. Registration for a higher degree would be possible for a suitable graduate. Starting salary £1,371 per annum (under review). Applications in writing including a curriculum vitae and the names and addresses of two referees, to the Director, Professor R. H. S. Thompson, Courtauld Institute of Biochemistry, The Middlesex Hospital Medical School, London W1P 5PR, by July 15, 1974, quoting ref. M.S.

(2496)

HISTOLOGY TECHNICIAN

required for Pharmacological and Toxicological Laboratory. Experience essential in the preparation and processing of animal tissues. Good working conditions. Pensions and Assurance Scheme. Application Forms from: Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London NI 2HB. (2489)

UNIVERSITY OF GLASGOW
DEPARTMENT OF CHEMISTRY

Applications are invited for an S.R.C. Postdoctoral Research Assistantship for work on the synthesis of enzyme models.

The appointment will be for one year in the first instance and, according to experience, within the salary range £2,118 to £2,412 per annum of the new Lecturers' salary scale which will be effective from October 1, 1974.

Applications giving a brief curriculum vitae and the names of two referees should be sent to Dr A. G. Cairns Smith, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ, from whom further information can be obtained. In reply please quote Ref. No. 3478M. (2498)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF HISTOLOGY
TECHNICIAN

required to work on a research project concerned with subcellular aspects of secretion in the anterior pituitary. An interest in radioimmunoassay, tissue culture or electron microscopy would be an advantage. Candidates should possess a degree, H.N.C. or at least O.N.C. in an appropriate subject. The appointment will be tenable for two years in the first instance. Salary range up to £1,920 per annum. Application forms may be obtained from the Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote ref. RV/N/276077. (2494)

ICI Pharmaceuticals Division

Graduate Biochemist

We have a vacancy for a Graduate Biochemist with a good honours degree in Biochemistry to work on the metabolism of parasites (helminths). Previous research experience would be an advantage, but knowledge of parasite biochemistry is not required.

The successful candidate will be expected to undertake original and applied research into helminth biochemistry, the mode of action of drugs on helminths, and the design of novel drugs, under the direction of a Research Scientist.

Pharmaceuticals Division is attractively situated in rural North Cheshire, within easy reach of main road and rail routes. Assistance given to married men in moving to this area is designed to attract and retain staff of high calibre.

Applications in writing, requesting an application form should be sent to:

M F Losse
Personnel Officer
ICI Pharmaceuticals Division
Mereside, Alderley Park
Macclesfield, Cheshire.

(2551)

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH
NEW ZEALAND

Scientist

The Physics and Engineering Laboratory of the Department of Scientific and Industrial Research has a vacancy for a scientist at the Geophysical Observatory, Christchurch.

The Upper Atmosphere Division of the Physics and Engineering Laboratory, of which the Geophysical Observatory is part, is undertaking research into the physics of the ionosphere and magnetosphere, using a variety of experimental research and observatory ionosondes and magnetics) programmes from the Pacific Islands to Antarctica. Satellite telemetry facilities are also available.

Qualifications: 1st class honours degree in physics plus relevant experience.

Salary: Up to NZ$10,232 p.a.

Further information may be obtained from the High Commissioner for New Zealand, New Zealand House, Haymarket, London SW1Y 4TQ. Applicants should quote Ref. Imm. 2/284 and forward applications to the High Commissioner for New Zealand by August 1 1974.

(2487)

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH
NEW ZEALAND

Scientist

The Industrial Chemistry Section of the Chemistry Division, DSIR, Lower Hutt, has a vacancy for a Chemical Engineer or Chemist with experience in the treatment of industrial waste. Duties will be to develop treatment processes for industrial effluents, and to carry out both laboratory and pilot scale studies.

Qualifications: Good Honours degree or Ph.D. required.

Salary: Up to NZ$10,232 p.a. depending on qualifications and experience.

Further details, passage assistance etc., may be obtained from the High Commissioner for New Zealand, New Zealand House, Haymarket, London SW1Y 4TQ. Applicants should quote Ref. Imm. 2/285 and forward applications to the New Zealand High Commissioner by July 31 1974.

(2486)

THE ANIMAL VIRUS RESEARCH INSTITUTE

PIRBRIGHT, WOKING, SURREY

Applications are invited from Honours graduates interested in chemical and biochemical studies of the structure and multiplication of animal viruses, for a post in the Biochemistry Department. Facilities are available for the successful applicant to work for a higher degree.

The appointment will be in the S.O. (£1,435 to £2,329) or H.S.O. (£2,221 to £2,854, grade, starting salary depending on qualifications and experience. FSSU Superannuation Allowance of 4½%. House available for married man. Application forms and further particulars from Secretary. (2513)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BOTANY
LECTURER IN APPLIED ECOLOGY

Applications are invited for the post of Lecturer in applied ecology commencing on October 1, 1974. Applicants should possess a good honours degree and postgraduate experience in plant ecology, soil science or agronomy. An interest or experience in applying ecological principles to solving practical problems of the environment such as land reclamation or pollution would be an advantage.

There will be excellent opportunities for collaborating with a very active research group in environmental rehabilitation which has strong links with industry and local government.

Initial salary within the range £2,118 to £2,412 on a scale rising to £4,896 per annum.

Applications together with the names of three referees should be received not later than July 19, 1974 by the Registrar, The University P.O. Box 147, Liverpool L69 3BX from whom further particulars may be obtained. Quote ref. RV/N/276073. (2495)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF MEDICAL BIOCHEMISTRY

Applications are invited for a Postdoctoral RESEARCH ASSOCIATESHIP financed by the British Heart Foundation. The project involves the isolation of endothelial cells from major blood vessels, their establishment in culture and studies of the synthesis of the collagen and glycoprotein components of the endothelial basement membrane. Experience in cell culture and/or protein synthesis would be advantageous. The appointment from October 1, 1974 is tenable for two years. Salary range p.a.: £2,118 to £2,412 plus F.S.S.U. Applications giving the names of two referees should reach the Secretary, Department of Medical Biochemistry, University of Manchester Medical School, Manchester M13 9PT, as soon as possible. (2481)

Bass Charrington

Physical Chemist
BURTON-ON-TRENT

A Graduate with a good honours degree specialising in Physical Chemistry is required by a major Brewery Company for a period of three years to work on projects related to the Physico-Chemical characteristics of foam formation and collapse in beer.

The appointment and planned projects would be most applicable to a recent graduate wishing to proceed to an external Ph.D. qualification whilst working in an industrial research environment and earning a competitive salary with attractive fringe benefits.

Detailed applications should be sent to:—

The Staff Personnel Manager,
Bass Production Limited,
High Street,
Burton-on-Trent DE14 1JZ.

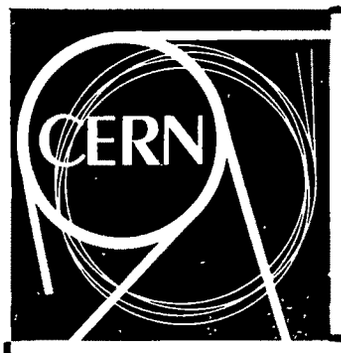
(2564)

TRENT POLYTECHNIC NOTTINGHAM
DEPARTMENT OF LIFE SCIENCES
SENIOR LECTURER IN BIOCHEMICAL PHARMACOLOGY
LECTURER GRADE II IN BIOCHEMISTRY

To commence September 1974 or as soon as possible thereafter. Salary scales (subject to ratification): Senior Lecturer—£3,525 to £3,915(bar) to £4,212; Lecturer Grade II—£2,700 to £3,474.

For further particulars and application forms please send self-addressed foolscap envelope to The Chief Administrative Officer, Trent Polytechnic, Burton Street, Nottingham NG1 4BU. Closing date July 5. (2474)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(UNIVERSITY OF LONDON)
COURTAULD INSTITUTE OF BIOCHEMISTRY
RESEARCH ASSISTANT



Applications are invited from Honours Graduates in Biochemistry for the above post to work with Dr B. Ketterer on studies of cellular proteins which interact with carcinogens. Registration for a Ph.D. degree would be expected. Starting salary £1,371 per annum (under review). Applications in writing including a curriculum vitae and the names and addresses of two referees, to the Director, Professor R. H. S. Thompson, Courtauld Institute of Biochemistry, The Middlesex Hospital Medical School, London W1P 5PR by July 15, 1974, quoting ref C.R.C. (2506)

Electron Microscopy Technician (grade 3)

Required to assist generally in a fully equipped unit serving research and teaching in Biological Ultrastructure. The post offers opportunities in the development of techniques and instrumentation for applicants of appropriate interests and experience. Salary in the range £1,825 to £2,095 per annum.

Applications in writing to Mr. R. Adams, Departmental Superintendent, Department of Botany, Imperial College, London SW7 3BB.

(2473)

European Organization for Nuclear Research

Organisation Européenne pour la Recherche Nucléaire

CERN is a modern research laboratory, situated near Geneva, which offers first-class social and financial conditions of employment, and the opportunity to work in an international atmosphere.

A junior staff position in the Theoretical Study Division is open to scientists working on theoretical aspects of elementary particle physics or intermediate energy nuclear physics. Applicants should have a few years of post-doctoral experience and have accomplished interesting original research.

This position is for a period of three years, with the possibility of renewal for a further three years, and implies a basic salary of between 44,000 Sw.Frs., and 55,000 Sw.Frs., per annum, tax free, according to the qualifications of the selected person.

Candidates are invited to apply irrespective of nationality. However, among candidates with similar qualifications, preference will be given to nationals of CERN Member States.

Applications, including curriculum vitae and list of publications, are invited. They should be addressed to:

Professor D. Amati, Leader of the Theoretical Study Division, CERN, 1211 Geneva 23, Switzerland, and received before 15 August, 1974.

(2543)

UNIVERSITY OF OXFORD
PROFESSORSHIP OF CLINICAL BIOCHEMISTRY

The electors intend to proceed to an election to this professorship, which has been established with effect from August 1, 1974. The stipend is £7,559 a year. Further particulars may be obtained from the Registrar, University Registry, Broad Street, Oxford, by whom applications (twelve copies), naming three referees but without testimonials, should be received not later than July 13, 1974.

(2491)

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF ZOOLOGY

The University invites applications for the post of DEMONSTRATOR in the Department of Zoology. The appointment will be for a period of three years, subject to annual renewal, and will be tenable from September 1, 1974. Preference will be given to candidates experienced in animal behaviour (including relevant aspects of neurophysiology). Applicants should possess a higher degree or equivalent postgraduate research experience.

Salary will be at an appropriate point on the scale £1,929 to £2,223 (from October 1974 £2,118 to £2,412) according to age, qualifications and experience. Membership of F.S.S.U. required.

Further particulars may be obtained from the Registrar, The University, Newcastle upon Tyne NE1 7RU with whom applications (3 copies), together with the names and address of three referees, should be lodged not later than July 12, 1974. Please quote reference N. (2483)

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MEDICAL PHYSICS
PHYSICIST

required for duties in hospital isotope service, which includes thyroid, haematological and scanning procedures. The department has an extensive research and teaching programme. Some experience of radiotherapy physics would be an advantage.

Salary on Lectureship Scale £1,929 to £4,548 (after October 1, 1974 £2,118 to £4,896) with placing according to qualifications and experience.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies), giving two referees, should be lodged by July 8, 1974. (2500)

THE UNIVERSITY OF LEEDS
DEPARTMENT OF COLOUR CHEMISTRY

Applications are invited for a RESEARCH STUDENTSHIP to examine novel triarylmethane dyes of potential biological interest.

The project is financed by Allen & Hanbury's Research Ltd., and the grant has the same value as a SRC Studentship. The person appointed will be able to read for a higher degree.

Applicants should have a good Honours degree (or equivalent) in Chemistry and should write by July 7 to Dr G. Hallas, Department of Colour Chemistry, The University, Leeds LS2 9JT, from whom further particulars may be obtained.

(2499)

EDITORIAL ASSISTANT

required for Genetics Abstracts. Degree in Biological Sciences preferably in Genttcs essential, foreign language an advantage. Apply in writing to Dr. E. S. Krudy, Information Retrieval Limited, 1 Falconberg Court, London W1V 5FG. (2504)

UNIVERSITY OF NOTTINGHAM
ELECTRONICS ENGINEER
SENIOR SCIENTIFIC OFFICER

Applications are invited for a new technical post in the Department of Zoology from qualified electronics engineers with experience of servicing and designing electronic equipmept. The appointee will occupy a senior position in a new Electrosphysiology Research/Teaching Unit in the Zoology Department and will be expected to play a major rôle in advising graduate students and academic staff on the technical aspects of their research and teaching programmes. Previous experience of biomedical electronics would be an advantage. Salary within the range £2,382 to £2,751 (bar) £2,862 to £3,555 per annum.

Application forms from Staff Appointments Officer, University of Nottingham, University Park, Nottingham quoting ref. 375. Closing date: June 30, 1974. (2484)

RESEARCH POST AT THE OXFORD HAEMOPHILIA CENTRE

Applications are invited from medically qualified graduate scientists with some experience of research in some aspect of haemostasis for appointment as a member of a small team of Medical Research Council staff working at the Oxford Haemophilia Centre, under the direction of Dr Rosemary Biggs The successful candidate will be expected to cooperate with other members of staff on projects already progressing at the Centre and to initiate a research project or projects in the general field of interest of the work at the Centre. The work of the M.R.C. staff is integrated with that of the N.H.S. Clinical Unit, many projects being undertaken jointly, and an Honorary Clinical contract with the United Oxford Hospitals may be sought at a level appropriate for the successful candidate The M.R.C. and N.H.S. staff also work in close co-operation with the staff of the Lister Institute Plasma Fractionation Laboratory and joint research projects may be planned. The appointment will be to the M.R.C. staff on the appropriate scientific grade and will initially be for a period of five years with the possibility of renewal at the end of this period. Superannuation provision.

Applications should be addressed to Dr Rosemary Biggs, Director, Oxford Haemophilia Centre, Churchill Hospital, Headington, Oxford OX3 7LJ (2477)

INFORMATION SCIENTIST

Senior management in the Malaysian natural rubber industry needs to be kept informed of techno-economic and statistical trends in rubber consuming countries. An abstracts-based information bulletin has been started as the core of a new information service for management, and a computerized retrieval system is now being developed.

A qualified information scientist is required to develop and operate this service at the Malaysian Rubber Producers' Research Association, which is shortly moving to new premises on an attractive site near Hertford.

Application forms and further details from the:—

Director,
Malaysian Rubber Producers' Research Association,
56 Tewin Road,
Welwyn Garden City,
Herts, AL7 1AD.

(2533)

POSITION AVAILABLE

ENTOMOLOGIST, ASSISTANT OR ASSOCIATE PROFESSOR RANK

Qualifications: Recent Ph.D., preferably with teaching, research or extension experience in applied entomology.

Duties: Teaching—To offer a course in economic entomology to the Diploma in Agriculture students; to assist in entomology courses for degree students; to supervise graduate students.

Research—To conduct research in pests of vegetables, ornamentals or greenhouse crops.

Extension—To provide extension information in his area of research; to identify insects sent in by home owners, and others and provide information concerning them.

Salary: Open.

Apply: Professor F. L. McEwen, Chairman, Department of Environmental Biology, University of Guelph, Guelph, Ontario, Canada N1G 2W1. (2493)

KINGSTON POLYTECHNIC
RESEARCH ASSISTANTSHIP
SCHOOL OF GEOLOGY

The research assistant will be required to work upon A SEDIMENTARY AND FAUNAL ANALYSIS OF SOUDLEYAN/LONGVILLIAN (CARADOC) ROCKS IN SNOWDONIA, NORTH WALES.

This research will be conducted under the supervision of Dr. J. S. W. Penn. The selected candidate will be expected to register for a higher degree. Commencing salary £1,427.

Application forms and further details from Appointments Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. (2502)

THE MIDLAND CENTRE FOR NEUROSURGERY & NEUROLOGY

PATHOLOGY DEPARTMENT

Senior Technician—Electron Microscopy

Applications are invited for the post of Senior Technician in Electron Microscopy. The department is engaged on studies of the ultrastructural pathology of material from the central and peripheral nervous systems and muscle. Two Siemens microscopes are in use and an unusually comprehensive range of equipment is available. The successful candidate will be required to assist in instrument maintenance and in developing electron microscopy. Previous experience in election microscopy necessary.

The Department may be visited by appointment (021-558 2311).

Applications with names of two referees to
Area Administrator,
P.O. Box 50,
Shaftesbury House,
High Street,
West Bromwich,
B70 9LE.
(2526)

Faculty Position

ELECTRICAL ENGINEERING

Applications are invited for a position as Associate or Full Professor in the field of Electronic or Communication Engineering. Ph.D. and industrial experience required. Duties will include undergraduate and postgraduate teaching and laboratory development. The applicant should be able to initiate and lead research in electronics engineering; particular interest in communications or biomedical engineering would be preferable. Salary according to qualifications. Send applications to: O. K. Gashus, Head, Electrical Engineering Department, Nova Scotia Technical College, Halifax, Nova Scotia, Canada. (2527)

Ph.D or M.D. TO LEAD IMMUNOLOGICAL RESEARCH DEPARTMENT

A Ph.D. or M.D. is required by a French Pharmaceutical Research Laboratory of international size to direct a new Department: Immunology applied to therapeutics.

He (she) must be able to formulate research programmes and develop them.

Preference is given to a Ph.D. of (and) M.D. with about ten years postgraduate experience in industrial research.

No matter the nationality.

Send your resume in complete confidence to Box No. 2531, Nature, T. G. Scott & Son Ltd., Clement's Inn, London WC2A 2ED. (2531)

University College of North Wales
CHAIR OF FORESTRY

Applications are invited for the post of Professor and Head of the Department of Forestry and Wood Science.

The appointment will be from a date to be arranged and the salary will be not less than £5,973.

Further particulars can be obtained from the Secretary and Registrar, University College of North Wales, Bangor, LL57 2DG. TEN copies of the application (ONE from overseas candidates), together with the names of three referees, should be sent to reach the Secretary and Registrar by July 8, 1974. (2532)

STRANGEWAYS RESEARCH LABORATORY CAMBRIDGE

Cell biologist required to join a group in the Strangeways Research Laboratory concerned with cell motility in relation to cancer invasion. The work will mainly be in electron microscopy and tissue culture. The post which is financed by the M.R.C., is for a maximum of 4 years at a commencing salary of not less than £1,830 + F.S.S.U. Applications, together with the name of two referees should be sent to the Administrative Secretary (Ref. M.A.) Strangeways Research Laboratory, Wort's Causeway, Cambridge. (2534)

UNIVERSITY OF WESTERN AUSTRALIA
Perth

CHAIR IN MATHEMATICS

Applications for appointment to a Chair in the Department of Mathematics during 1975, preferably before September, are invited from persons who have made significant contributions in the field of applied mathematics and who, preferably, have had experience of teaching at university level. The present research strength of the Department in applied mathematics is primarily in classical areas, but applications will be welcomed from persons with interests in other areas.

The appointee will replace Professor J. J. Mahony who has resigned from the end of the year and will occupy one of four Chairs in the Department. Professor A. L. Blakers (Mathematics Education) and Professor J. P. O. Silberstein (Pure Mathematics) occupy two of the other Chairs. The third, which is earmarked for Mathematical Statistics, is vacant. The headship of the Department is filled periodically from among the professors by decision of the University Senate. The present Head (Chairman) of the Department is Professor Blakers. The appointee will share in the determination of policy and in the administration of the Department.

The present salary for a Professor is SA19,614 p.a. Benefits include superannuation similar to FSSU, fares to Perth for appointee and dependent family, removal allowance, study leave, long service leave and housing loan scheme. Further information incuding conditions of appointment and details of present staff and research in the applied area may be obtained from the Staffing Officer, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications in duplicate stating full personal particulars, qualifications, experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Western Australia 6009, by 20 July 1974. (2519)

RESEARCH ON TRANSFERABLE DRUG RESISTANCE ENTERIC REFERENCE LABORATORY

Applications are invited for two posts in the Enteric Reference Laboratory, Public Health Laboratory Service, Colindale, directed by Professor E. S. Anderson. Successful candidates will join a team investigating transferable drug resistance.

(1) A microbial geneticist to study epidemiological and ecological aspects of transferable drug resistance in enterobacteria.

(2) A microbial or molecular geneticist for research on the genetic and molecular characterisation of plasmid transfer systems.

Candidates with a 1st or 2nd class honours degree or a Ph.D. will be considered. Starting salary in accordance with age and experience.

Application with full curriculum vitae and names of 2 referees to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (2517)

Imperial College
Department of Biochemistry

BIO-ORGANIC CHEMIST

Applications are invited for an S.R.C. Post-Doctoral Assistantship for work on the Biosynthesis of Fungal Sesquiterpenes in collaboration with Dr G. Mellows.

Candidates should have an interest in and preferably experience of biological chemistry. The appointment is tenable for one year, commencing October 1, 1974. Salary range up to £2,247 p.a. with FSSU, plus £162 London allowance.

Applications, including curriculum vitae, research experience and the names of two referees should be sent as soon as possible to Dr G. Mellows, Department of Biochemistry, Imperial College, London SW7 2AY. (2525)

THE ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY
(University of London)

A Graduate Research Assistant is required by the Department of Physical Sciences to study ion-exchange and adsorption phenomena at the surface of hydroxyapatite, the mineral constituent of bones and teeth. Applicants are expected to have or to obtain a good degree in Physics or Chemistry. The appointment, which is for three years in the first instance, will be on a salary scale from £1,417 to £1,713 (under review) plus a London Allowance and F.S.S.U. benefits. Alternatively a part-time appointment would be considered.

Further particulars may be obtained from Dr N. E. Waters and applications should be sent to the School Secretary. (N) (2520)

RESEARCH MICROBIOLOGIST

Following a promotion a vacancy has arisen at our Research Laboratories in Edgbaston, Birmingham, for a chemical microbiologist to work on the production of chemicals and enzymes by fermentation processes.

Applicants, aged about 25, should have at least an upper second class degree preferably in chemistry with two or three years post graduate microbiological experience either academic or industrial. The Company operates staff bonus and pension schemes and assistance with removal expenses will be given where appropriate. Write, giving full details of education and career to date to:

Mr. P. E. Milsom,
JOHN & E. STURGE LTD.,
1 Wheeleys Road,
Birmingham, B15 2LE.
(2547)

WANTED
CYTOGENETICIST

To join team investigating genetic and immunological aspects of birth defects and leukaemia. The main responsibility of the successful applicant will be to carry out, with technical assistance, chromosome studies on amniotic cells and lymphocytes as part of the diagnostic and the research activities of the department. Previous experience desirable. This post is annually renewable initially and will be appointed on the appropriate Whitley Council scale.

Apply to:—

Dr. R. Harris,
Department of Medical Genetics,
St. Mary's Hospital,
Manchester 13,

stating experience and giving the names of two individuals to whom reference may be made. (2536)

UNIVERSITY OF NEW SOUTH WALES

PROFESSOR OF BIOCHEMISTRY

Applications are invited for appointment to the third chair to be established in the School of Biochemistry. A Chair of Biochemistry is held by Professor E.O.P. Thompson, the present Head of School, and Dr W. J. O'Sullivan has recently accepted the Chair of Medical Biochemistry. Applicants should have appropriate quafifications and research experience in a major field of biochemistry, with an interest in university teaching and a capability for academic leadership.

The School has extensive undergraduate programmes for students in science, applied science and medicine as well as postgraduate research activities for higher degrees. The new professor will supervise and participate in teaching and examining undergraduate and postgraduate students in the School, with particular reference to the lecture courses and practical training for students in science and applied science, and will engage in and promote research and advanced study in the field of his chair.

Salary $A19,614 per annum. Subject to the consent of the University Council, professors may undertake a limited amount of higher consultative work. The University reserves the right to fill any chair by invitation.

Details of appointment, including superannuation, study leave and housing scheme, may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close in Australia and London on **August 30, 1974.** (2522)

WHITTINGTON HOSPITAL LONDON N.19.

DEPARTMENT OF CHEMICAL PATHOLOGY

BASIC GRADE BIOCHEMIST

Required to work in this well-equipped Department.

The Post would suit a recent graduate and could provide a comprehensive training in Clinical Chemistry.

For further details please contact Miss S. McFarlane, Senior Biochemist, Whittington Hospital, Highgate Hill, London N.19. (Tel: 01-272 3070 Ext. 233).

Application forms available from Hospital Personnel Officer (Address as above). (2518)

CHARING CROSS HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF BIOCHEMISTRY

TECHNICIANS

Applications are invited for the following posts:

1. Senior research technician to join research group headed by Professor A. Neuberger, F.R.S., working on glycoproteins, supported by the Medical Research Council. Applicants should hold HNC, AIST or equivalent qualifications and have suitable laboratory experience for this senior position. This appointment is from 1st July 1974 until 31st March 1977. The salary is on Whitley scale commencing at £2,400 plus London weighting.
2. Research technician to join Professor A. Neuberger's group working on the biosynthesis of porphyrins, supported by the Wellcome Trust. Applicants should hold recognisable qualifications for this post which is from 1st July 1974 until 31st March 1977, salary £1845 plus London Weighting. Applications, in writing, to the Secretary, Charing Cross Hospital Medical School, Brandenburgh House, Fulham, W.6. (2542)

THE NORTH OF SCOTLAND COLLEGE OF AGRICULTURE

Applications are invited for the post of SPECIALIST ADVISORY OFFICER in Animal Husbandry. In addition to Specialist Advisory Work duties include participation in Research and Development. Posting, for some years at least, will be to Inverness to serve the six counties of the Highland Region.

Salary Scale: Grade IV £1,584-£2,148

Grade III £2,328-£4,061

Cost of living safeguard allowance payable in addition. Superannuation Scheme.

Forms of application and further particulars of the post (Reference Number 46/74) may be obtained from the Secretary, The North of Scotland College of Agriculture, School of Agriculture Building, 581 King Street, Aberdeen AB9 1UD with whom application should be lodged **not later than 10th July, 1974.**

(2545)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF CANCER STUDIES

Research Technician, Grade III, is required to work on a project involving a study of the mechanism of carcinogenesis by chemical compounds. Biochemical work, tissue culture work and some animal experimentation will be involved. Preference will be given to candidates with experience in either biochemistry or tissue culture techniques. Applicants must have an ONC in an appropriate subject and several years laboratory experience. Salary will be on the scale £1,650-£1,920. Applications should be sent with a curriculum vitae and the names of two referees to the Personnel Department, University of Birmingham, Birmingham, B15 2TT. Ref. 450/B/264. (2546)

UNIVERSITY OF READING

DEPARTMENT OF PHYSIOLOGY AND BIOCHEMISTRY

RESEARCH DEMONSTRATOR

required for work on the regulation of luteinising hormone secretion in the chicken, involving the use of neurophysiological and radioimmunoassay techniques. Candidates should have a degree in Physiology or Zoology or a related discipline and may register for a higher degree. The post will be for three years from October 1, 1974 with possible extension and involves about 12 hours demonstrating per week during term. Salary in the scale £1,047 by £51 to £1,149 p.a. (under review). Apply with names of two referees, quoting Ref. TN 48, to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. (2560)

UNIVERSITY OF BRISTOL

Postdoctoral Protein Crystallographer

Applications are invited for an S.R.C. post to work on the crystal structure of pyruvate kirase or phospho glucose isomerase. The research will involve the development of computer programs to handle data collected by an oscillation camera. The appointment is for a period of two years with an initial salary of up to £2,058 per annum depending on experience. Previous research experience in crystallography is essential.

Applications, including a brief curriculum vitae and names and addresses of two referees, should be sent to Dr. H. Kinase, Department of Biochemistry, University Walk, Bristol BS8 1TD. (2558)

JOHN INNES INSTITUTE

DEPARTMENT OF ULTRASTRUCTURAL STUDIES

The Department of Ultrastructural Studies is accommodated in a new laboratory with extensive facilities for studying plant cell systems with the aid of electron microscopy and light microscopy.

A vacancy exists in the Department for an assistant to work on the ultrastructure of plant cells and protoplasts. An interest in the visualisation of cell structure is essential. Some experience in microscopy will be an advantage but the successful applicant will be given training in electron microscopy and tissue culture techniques.

The appointment will be as a SCIENTIFIC OFFICER (£1,435 to £2,329) or ASSISTANT SCIENTIFIC OFFICER (£961 to £1,729). Grade and starting salary will be determined by qualifications and experience. H.N.C. or pass degree qualifications are required for appointment to the Scientific Officer grade. Superannuation benefits are provided under the Institute's Scheme for Clerical and Technical Staff with 5¼% allowance in addition to salary to offset contributions.

Applications with full curriculum vitae and the names of two referees should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich NOR 7OF, by July 5, 1974. (2540)

TECHNICIAN (Grade 3)

required in Department of Microbiology, University of Reading, to assist in research on bacterial classification and to prepare materials for classes. Interest in photomicrography an advantage. Salary in scale £1,650 to £1,920 p.a. Apply stating qualifications and experience and names of two referees, quoting Ref. TN46, to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH. (2559)

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES

Applications are invited for a Lectureship in the above Department in the School of Agriculture. Areas of interest should preferably include the regulation of enzyme activities, the control of photosynthetic processes, and cellular aspects of growth and development, although other areas will not necessarily be excluded. The salary will be on the Lecturers scale: £2,118 to £4,896 although the appointment will initially be made within the first three points of the scale. The appointment is tenable from October 1, 1974.

Application forms and conditions of appointment available from Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Please quote ref. 377. Closing date June 30, 1974. (2553)

INSTITUTE FOR MARINE ENVIRONMENTAL RESEARCH, EDINBURGH

ECOLOGISTS

The research programmes of the Edinburgh Oceanographic Laboratory of I.M.E.R. are designed to describe and analyse variability and to formulate models of pelagic ecosystems, based largely on the Continuous Plankton Recorder survey of the North Atlantic Ocean and North Sea for which 27 years' data and computing facilities are available.

Applications are invited for two posts in the existing team of biologists and physicists at Edinburgh which is expected to move to Plymouth within the next three years:

ZOOPLANKTON ECOLOGIST (Post 38): Research on spatial and temporal variability, and population dynamics, of zooplankton in the C.P.R. survey. First or good second-class honours in zoology, preferably with experience of marine ecology and knowledge of computing.

SYSTEMS ECOLOGIST (Post 42): Research on structure and dynamics of plankton communities in relation to environmental variability, leading to formulation and validation of models of pelagic ecosystems. First or good second-class honours in a relevant biological or mathematical science, with experience of ecosystem analysis and modelling.

Grades and starting pay dependent on age, qualifications and experience. Candidates will be considered for appointment at Higher Scientific Officer/Senior Scientific Officer level (salary range £2,221 to £3,895) and exceptionally well qualified candidates will be considered for Principal Scientific Officer (£3,715 to £4,895) (Scales under review).

Non-contributory Pension Scheme.

For application forms or further particulars write (specifying post 38 or 42) to the Director, Institute for Marine Environmental Research, 67/69 Citadel Road, Plymouth PL1 3DH, Devon.

CLOSING DATE: JULY 10, 1974. (2541)

UNIVERSITY OF SURREY LECTURER/INDUSTRIAL TUTOR

DEPARTMENT OF BIOCHEMISTRY

Applications are invited from suitably qualified graduates with experience in the pharmaceutical or food industry for this new post in the Department of Biochemistry. The successful candidate will be required to organise the year of industrial experience of students reading for the 4-year B.Sc. Courses in Biochemistry and Nutrition, and to participate in the teaching, administration and research of the Department.

The teaching of the Department includes courses in biochemistry, clinical biochemistry, food science, nutrition, pharmacology and toxicology. Preference will be given to candidates with teaching/research interests in food science, pharmacological, or clinical biochemistry.

Salary, within the scale £2,118 to £4,896 per annum, with F.S.S.U., from October 1, 1974.

Further particulars of the post may be obtained from the Academic Registrar (L.F.G.), University of Surrey, Guildford GU2 5XH. Telephone: Guildford 71281, extension 452, and to whom applications should be sent, in the form of a curriculum vitae, including present salary and the names and addresses of two referees, by Friday, July 12, 1974. (2552)

THE ROYAL FREE HOSPITAL

DEPARTMENT OF NEUROLOGY

RESEARCH ASSOCIATE

Postdoctoral fellow required for work in muscle spindle morphology. Preference will be given to those with experience in electron microscopy.

The post is available from September 1, 1974 and the appointment would be for 3 years. Salary to a maximum of £2,232 first year depending on qualifications and experience.

Applications, naming two referees, to the Secretary, Department of Neurology, The Royal Free Hospital, Grays Inn Road, London WC1X 8LF. (2538)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF SPACE RESEARCH

Applications are invited for two posts, supported by S.R.C. grants:

X-RAY ASTRONOMY

Research Associate to carry out theoretical and laboratory studies of grazing incidence optical systems for use in X-ray telescopes. Previous experience of X-ray techniques useful but not essential. The posts is available for two years in the first instance.

ION-MOLECULE COLLISIONS

Research Associate within a group carrying out measurements of ion-ion and ion-molecule reaction rates using an advanced flowing afterglow apparatus. Experience with these techniques or with spectroscopic techniques would be advantageous but is not essential. The post is available for three years.

Salary scale (under review): Research Associate £1,569 to £2,223: Exceptionally: Senior Research Associate £2,223 to £2,718 plus F.S.S.U.

Applications (3 copies) naming 3 referees to the Assistant Registrar (S), University of Birmingham, Birmingham B15 2TT by July 22, 1974. Quote Ref. NL7. (2562)

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH
MOLECULAR GENETICIST

A Scientist with postdoctoral experience is required to join a small group working on the molecular biology and genetics of yeast. Primary interests of the group are in the replication and function of nuclear and mitochondrial DNA and of the molecular and genetic interrelationships between the nuclear and mitochondrial genomes.

Incremental salary according to age and qualifications within the range £2,223 to £3,378 p.a. plus £162 p.a. London Allowance and F.S.S.U. provision.

Applications, giving the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA. (2565)

SEALE-HAYNE COLLEGE
LECTURER IN THE DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited from suitably qualified AGRICULTURALISTS or BIOLOGISTS. Candidates should have interests in one or more of the following:

CROP PHYSIOLOGY
ANIMAL PHYSIOLOGY
ECOLOGY

The main courses taught at the College include five Higher National Diplomas, two Ordinary National Diplomas as well as post-graduate/post-diploma certificate courses.

The appointment will be at either the Lecturer Grade I or Lecturer Grade II, Scales of Salaries for Teachers in Further Education, according to age and experience. Further particulars may be obtained from The Principal, Seale-Hayne College, Newton Abbot, Devon, to whom applications should be sent by July 12, 1974. (2566)

PHARMACOLOGISTS/ TOXICOLOGISTS

Honours Graduates/Postdoctoral Fellows, with some experience preferred, required for research and toxicological studies of compounds of potential therapeutic importance. Excellent opportunities for advancement in modern, well-equipped laboratory. Pension and Assurance Scheme. Application forms from the Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. (2563)

UNIVERSITY COLLEGE DUBLIN
APPOINTMENT IN PHARMACOLOGY

Applications are invited for a teaching post in the Department of Pharmacology. Candidates must have a Ph.D. or an equivalent qualification *either*

(i) in pharmacology or physiology

or

(ii) in a cognate subject, provided that the candidate has had a significant undergraduate broad training in physiology.

The current salary scales are:
College Lecturer £3,514 by £162 to £4,648.
Assistant Lecturer £2,420 by £129 to £3,323.

Entry point on the relevant scale will be in accordance with qualifications and experience.

A non-contributory pension scheme and family allowances are additional to salary. An alternative contributory F.S.S.U. type scheme is also available.

Further information and details of application procedure may be obtained from:
Mr J. P. MacHale,
Secretary and Bursar,
University College,
Belfield,
Dublin 4.

Latest date for receipt of completed applications is Friday, July 5, 1974. (2537)

INSTITUTE OF CANCER RESEARCH
SUTTON, SURREY BRANCH
RADIATION CHEMIST/BIOCHEMIST Ph.D.

A vacancy exists on the full time research staff for a suitably qualified scientist to work within an M.R.C. sponsored research program. The successful applicant will be applying pulse radiolysis and other radiation techniques to radiobiology and radiotherapy problems. Salary on the lectureship scale (M.R.C. Grade II) with F.S.S.U. Candidates from overseas who may be attending the Seattle Congress of Radiation Research July 14-20 could be interviewed there by contacting Professor Boag.

Application in duplicate with names of two referees should be sent to the Secretary, 34 Sumner Place, London SW7 3NU, quoting Ref. 300/9/75(a). (2535)

THE NEW SOUTH WALES INSTITUTE OF TECHNOLOGY
SYDNEY, AUSTRALIA
PRINCIPAL LECTURER AND HEAD OF DEPARTMENT OF CELLULAR PATHOLOGY
in the
SCHOOL OF LIFE SCIENCES
SALARY $A15,744 to $A16,389 p.a.

The School occupies a new six-storey building adjacent to a large teaching hospital (Royal North Shore). There are well equipped laboratories for general biology, biochemistry, microbiology, environmental biology, physical biology and biomedical subjects.

The appointee will be responsible to the head of the School for the teaching and the development of degree level programmes in cellular pathology.

This will include developing courses in haematology, blood storage, histopathology and histochemistry. The appointee will also be required to study current trends in the fields mentioned, and to make recommendations on new undergraduate and postgraduate courses.

It is anticipated that the appointee will be medically qualified, possess appropriate postgraduate qualifications and have substantial professional experience. Depending on his interests and experience he may be offered an association with the Royal North Shore Hospital, in which case a right of limited private practice may be approved under similar terms and conditions to other such appointments to the hospital.

The position is offered with tenure. Superannuation, long service leave and an appropriate housing loan scheme are available. Also fares will be paid for the successful appointee and a contribution will be made towards initial accommodation expenses.

Enquiries regarding the Institute may be made with the Agent-General, New South Wales Government Offices, 66 Strand, London WC2 5LZ.

Applications close with the Agent-General on July 26, 1974. (2549)

THE UNIVERSITY COLLEGE OF WALES
ABERYSTWYTH
DEPARTMENT OF PHYSICS

Applications are invited for postgraduate work in the Department of Physics for sesssion 1974-75. The Science Research Council is prepared to offer to suitable candidates a limited number of Research Studentships for ionosphere and space research and studies of atomic collisions in plasmas, shock and detonation waves, and the flow of non-Newtonian fluids.

The Science Research Council has also accepted the postgraduate course on Physics of the Atmosphere as suitable for tenure of its Advanced Course Studentships.

Applications to Professor W. J. G. Beynon, F.R.S., Department of Physics, University College of Wales, Aberystwyth. (2478)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF CHEMISTRY

Postdoctoral Research Fellowship available from October 1974 to work on time-resolved fluorescence spectroscopy of aromatic molecules using mode-locked laser as excitation source. Starting salary up to £2,058 p.a. (under review) according to age and experience.

For further details please write to Dr D. Phillips, Department of Chemistry, University of Southampton, Southampton SO9 5NH. (2479)

THE SCHOOL OF PHARMACY
UNIVERSITY OF LONDON
RESEARCH STUDENTSHIP IN NEUROPHARMACOLOGY

An M.R.C. Research Studentship is available in the Department of Pharmacology for 3 years from October 1974 for neuropharmacological studies on sympathetic ganglia using electrophysiological and/or radio-active tracer techniques. Applicants should hold, or expect to attain, a good honours degree in a relevant subject and would be encouraged to register for a higher degree in the University of London.

Enquiries and applications should be made to Dr D. A. Brown, Department of Pharmacology, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX. (2497)

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF MEDICAL BIOCHEMISTRY
S.R.C. RESEARCH STUDENTSHIP

Applications are invited for an S.R.C. Research Studentship tenable from October 1, 1974, to study aspects of the biosynthesis of connective tissue macromolecules. Applicants are expected to have, or to obtain, a first or upper second class honours degree in biochemistry or an allied subject. Further information is available from Professor D. S. Jackson, Dept. of Medical Biochemistry, University of Manchester Medical School, Oxford Road, Manchester M13 9PT, to whom applications including a brief curriculum vitae and the names of two referees should be forwarded as soon as possible. (2480)

UNIVERSITY OF BIRMINGHAM
FACULTY OF MEDICINE AND DENTISTRY
DEPARTMENT OF PHYSIOLOGY

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP to collaborate in a study of the physiological and pharmacological regulation of renin release under the supervision of Dr B. Singer.

Starting salary up to £2,553 p.a. plus F.S.S.U., depending on age and experience.

Applications, with curriculum vitae, naming two referees, should be sent to Professor S. M. Hilton, Head of the Department of Physiology, The Medical School, Birmingham L15 2TJ. (2476)

UNIVERSITY OF LONDON
REACTOR CENTRE
(IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY)
S.R.C. RESEARCH STUDENTSHIPS

The Science Research Council is prepared this year to offer to suitable candidates a limited number of research studentships tenable at the University of London Reactor Centre. The value of these awards will be £695 p.a. (under review).

The areas of research for which studentships may be available are the following:

(i) Heat transfer studies on the U.L.R.C. reactor;

(ii) Fast reactor physics;

(iii) Neutron activation analysis.

Candidates who possess, or hope shortly to obtain, a good honours degree in a relevant subject are invited to write for further information to: Dr T. D. MacMahon, University of London Reactor Centre, Silwood Park, Sunninghill, Ascot, Berkshire SL5 7PY. (2503)

FELLOWSHIPS AND STUDENTSHIPS

KINGSTON POLYTECHNIC
RESEARCH STUDENTSHIP
SCHOOL OF CHEMICAL AND PHYSICAL SCIENCES

Applications are invited from good honours graduates in chemistry for a postgraduate research studentship. The successful candidate will be registered for a higher degree and will be involved in the study of the rôle of Boric Acid in the Synthesis of Anthraquinone Dyestuffs, in collaboration with Borax Consolidated Ltd. and I.C.I. (Organic Div.).

Enquiries to Dr P. B. Brindley, School of Chemical and Physical Sciences, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. (2501)

UNIVERSITY OF VIENNA
DEPARTMENT OF PHYSICS
POSTDOCTORAL RESEARCH FELLOWSHIP

Applications of Physicists and Metallurgists are invited for Basic Research on the deformation of metals. The group guided by Prof G. Schoeck works on plasticity of b.c.c. single crystals. Electron-microscopy, low temperature and hydraulic deformation facilities are available. Knowledge of German not essential. Salary approx. £2,000 p.a., after tax. Address applications and enquiries to H. Kirchner, II. Phys. Inst., A-1090 Strudlhofgasse 4. (2505)

LANCHESTER POLYTECHNIC
S.R.C. RESEARCH
STUDENTSHIPS

The Science Research Council is prepared to offer to suitable candidates two CASE Research Studentships at Lanchester Polytechnic to undertake research for a PhD Degree in the fields of:

SOLID STATE PHYSICS
CORROSION FATIGUE

Applicants should possess, or expect to obtain this summer, a first or upper second class Honours Degree or the equivalent in an appropriate subject.

Application forms and further particulars available from the Assistant Secretary (Personnel), Lanchester Polytechnic, Priory Street, Coventry CV1 5FB, returnable by July 8, 1974. (2475)

PH.D STUDENTSHIPS
INSTITUTE OF CANCER RESEARCH
(UNIVERSITY OF LONDON)

Two postgraduate Studentships will be available from October 1974 for studies on:

1. The chemical mechanisms involved in radiobiology and enzymology. The work will involve the application of rapid mixing techniques combined with pulse radiolysis, and rapid freezing, to investigate the radiation chemistry of radiosensitisers and of the mechanistics of fast enzymatic processes.
2. Development of tissue culture methods for the study of Sertoli cells from animal and human tissues with special reference to their structure and biochemical function.

Applicants should have or expect to have at least an upper second class honours degree in biochemistry, chemistry or possibly physics (No. 1) or in biochemistry, zoology or a related subject (No. 2).

Applications to The Dean, Institute of Cancer Research, 26 Neville Street, London SW7 3AS. (2482)

University of Kent at Canterbury

RESEARCH FELLOWSHIP
IN BIOCHEMISTRY

Applications are invited for a post-doctoral research fellowship involving work on nucleic acid and protein metabolism of malaria parasites and the effects of drugs. The appointment will be initially for one year, with the possibility of extension. Salary in the range £2,118-£2,412 with F.S.S.U. benefits. Application forms and further particulars may be obtained from the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, Canterbury, Kent CT2 7NH to whom completed applications should be returned by July 19, 1974. Please quote ref. A60/74. (2530)

UNIVERSITY OF BIRMINGHAM
NEUROCOMMUNICATIONS
RESEARCH UNIT

A vacancy occurs in the above Unit for a Research Fellow, preferably with relevant research experience, to study the electrophysiology of the mammalian cortex in relation to complex sound stimuli. Appointment for a period of one year from August 1, 1974, or as soon thereafter as possible.

Salary scale (under review): £1,929 to £2,223 p.a. or, exceptionally, to £2,388 p.a. plus F.S.S.U.

Further particulars from Assistant Registrar (RS), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, to whom applications (five copies) naming two referees should be sent by July 10, 1974. (2561)

THE EDINBURGH SCHOOL OF AGRICULTURE

RESEARCH STUDENTSHIP

Applications are invited for a three-year research studentship financed by the British Egg Marketing Board for work on biochemical aspects of food intake regulation in poultry. The successful candidate will be required to possess a good honours degree in biochemistry, physiology or agricultural science. The value of the award is £750 per annum plus post-graduate fees.

Further information and application form from the Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (2524)

NEW ZEALAND

Senior and Post-doctoral Research Fellowships

The New Zealand National Research Advisory Council invites applications for 10 Senior and Postdoctoral Fellowships to be taken up in New Zealand in 1975. The awards will be for scientific research in Government Departments. A good working knowledge of English is required.

The emoluments will be: Senior, within the range NZ$10,288 to NZ$15,265, Postdoctural NZ$8,637. All emoluments are taxable.

Senior Fellowships will normally be for a period of from nine months to year and Postdoctoral Fellowships for a period of from two to three years.

Application forms and further particulars may be obtained from: The Senior Administration Officer, National Research Advisory Council, Box 8004, Wellington, New Zealand; The Senior Scientific Adviser, New Zealand High Commission, New Zealand House, Haymarket, London SW1Y 4TQ England; from the New Zealand Embassy, 19 Observatory Circle, N.W., Washington D.C. 20008, U.S.A.; from the New Zealand High Commission, Suite 804, Commonwealth Building, 77 Metcalfe Street, Ottawa, Canada K1P 5L6; from the New Zealand High Commission, Commonwealth Ave., Canberra 2600, A.C.T., Australia; from the New Zealand Embassy, 20-40 Kamiyama-cho Shibuya-ku, Tokyo 150, Japan; from the New Zealand Embassy in Bangkok, Bonn, Brussels, The Hague, Jakarta, Lima, Paris, Rome, Saigon, Santiago, Seoul; from the New Zealand Consulate-General in Athens, Geneva, Los Angeles, New York, San Francisco, Sydney; from the New Zealand Commission in Hong Kong; and from the New Zealand High Commission in Kuala Lumpur, and Singapore.

Applications must reach the Council's office by September 30 1974.

(2488)

University of Aberdeen

DEPARTMENT OF ZOOLOGY

An S.R.C. Research Studentship is available in the Department of Zoology, University of Aberdeen, for any one of the following projects—

1. Characterisation of information transfer between macrophages and lymphocytes.
2. The effect of polyanions on immunosuppressed mice.
3. Tracheal gas composition and oxygen uptake in aquatic insects.
4. Ligand induced redistribution of cell surface receptors.
5. Electron microscope studies of uterine cancers.

Further information and applications forms may be had from Dr. D. T. Gauld, Department of Zoology, Tillydrone Avenue, Aberdeen AB9 2TN. (2528)

UNIVERSITY OF HULL
PSYCHOLOGY DEPARTMENT
RESEARCH STUDENTSHIP
SOCIAL PSYCHOLOGY OF PET-KEEPING

Applications are invited for this studentship which is sponsored by Pedigree Petfoods Ltd. Tenable for three years, the studentship commences in September 1974 and is valued at £1,200 tax free, per annum, with an annual allowance for research expenses.

Candidates should hold a first or second class honours degree in psychology. Some experience in market research or of field-work in a related area would be an advantage. Further details can be obtained from Mr J. G. M'Comisky, Department of Psychology, The University, Hull HU6 7RX.

Applications (three copies) giving the names of two referees, should be sent to the abovenamed by July 1, 1974. (2485)

THE UNIVERSITY OF LEEDS
PROCTER DEPARTMENT OF FOOD AND LEATHER SCIENCE

OPPORTUNITIES FOR POSTGRADUATE RESEARCH

Several postgraduate studentships will be available in the department from October 1974. Areas of work for which grants may be available are:

Application of food technology to the catering industry;
Basic studies of leather processing;
Biochemical aspects of utilisation of fish proteins, citrus waste, beet waste;
Carbohydrate-protein interactions;
Cereal foods of developing countries;
Electron-microscopy of foodstuffs;
Electron microscope studies in leather manufacture;
Fat-globule membrane in ice-cream;
Flavour studies using combined G.L.C.-mass spectrometry;
Fluidisation of particulate foods;
Lipid-protein interactions in relation to meats;
Mechanical behaviour and structure of skin and leather;
Microstructure of cakes with special reference to the rôle of emulsifiers;
Pectolytic enzymes;
Physical and chemical properties of flour doughs;
Rapid methods of food analysis;
Structure of proteins in foods; and
Studies of ancient leathers and parchments.

Depending on the area of interest, a good degree in chemistry, biochemistry, physics, chemical engineering, or a biological subject would be appropriate. All awards permit registration for a higher degree.

Enquiries and requests for application forms to Professor A. G. Ward, Procter Department of Food and Leather Science, The University, Leeds LS2 9JT. (2555)

POST DOCTORAL RESEARCH FELLOW

required to work in the Division of Experimental Pathology. The vacancy is for three years, and will involve some work being carried out in the Department of Experimental Pathology, University of Birmingham. The project is M.R.C. supported, and will be concerned with studies of the kinetics of lymphoid cells in the mouse. Background and experience in immunology, lymphoid physiology and/or autoradiographic techniques will be an advantage.

Applications with curriculum vitae and names of two referees to The General Secretary, Kennedy Institute of Rheumatology, Bute Gardens, London W6 7DW. (2548)

RESEARCH STUDENTSHIPS

Applications are invited for two three-year Research Studentships, tenable from October 1, 1974, at the M.R.C. Dunn Nutritional Laboratory, Cambridge, in the following areas:

(1) The relationship between protein metabolism and hormonal status in animals subjected to protein-energy malnutrition.

(2) The biochemical effects of riboflavin deficiency in an experimental animal, to relate the known parameters of subclinical riboflavin deficiency with biochemical lesions which may have pathological consequences. These studies will form part of a new programme, the aim of which is to examine various aspects of human nutritional status in relation to the water-soluble vntamins.

Applicants should have, or be expecting this summer, a first or upper second class honours degree, preferably in Biochemistry or Nutritional Science, and should send their curriculum vitae and names of two referees for (1) to Dr P. G. Lunn and (2) to Dr C. J. Bates, at the Dunn Nutritional Laboratory, Milton Road, Cambridge CB4 1XJ, not later than June 30, 1974. (2556)

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF APPLIED MATHEMATICS AND ASTRONOMY

Applications are invited from those possessing or expecting to have a First or Upper Second Class Honours Degree in Mathematics or Physics for two S.R.C. Studentships. The first is in the areas of astrophysics and general relativity and the second is in atomic scattering theory, plasma physics or solid state (with special reference to disordered systems or theory of small particles). Applicants will be expected to register for a Ph.D. Applications to Professor N. C. Wickramasinghe, Department of Applied Mathematics and Astronomy, University College, P.O. Box 78, Cardiff CF1 1XL. Please quote ref. 0594. (2557)

THAMES POLYTECHNIC

FACULTY OF ARCHITECTURE AND SURVEYING

RESEARCH STUDENTSHIP

A vacancy will be available in October for a Research Student to undertake research leading to a Higher Degree in either some aspect of energy conservation in buildings or the application of computers in building design. The research will be based at the Faculty of Architecture and Surveying, which is at Hammersmith, London, W.6. The applicant should hold or expect to achieve in 1974, a good honours degree in Physics, an Engineering discipline, Architecture or Surveying. A Science Research Council Studentship may be available to a suitably qualified applicant.

Please write for further information and application form to the Secretary, Thames Polytechnic, Wellington Street, London SE18 6PF. (2550)

GRANTS

THE NATIONAL KIDNEY RESEARCH FUND

invites applications for grants for renal research at units within the United Kingdom. Application forms are available from The Secretary, 184B Station Road, Harrow, Middlesex HA1 2RH (01-863 4460). Completed applications will be required by July 31, 1974. (2454)

NATIONAL VEGETABLE RESEARCH STATION

RESEARCH SCHOLARSHIP

Applications are invited from honours graduates (or those shortly to graduate) wishing to pursue further studies and obtain training in one of the lines of research in progress at the Station. The Scholarship value £700 per annum (under review), plus Univ. fees for higher degree, is tenable for two years, with possible extension to three years. The awards will date from 1st October, 1974.

Closing date for applications July 18, 1974.

Further particulars and application form from Secretary, NVRS, Wellesbourne, Warwick CV35 9EF. (2529)

LECTURES AND COURSES

CHELSEA COLLEGE
University of London
MSc COURSE IN CYBERNETICS

Applications are invited from suitably qualified graduates in related subjects for a two-year part-time evening course in Cybernetics commencing Thursday 10th October, 1974 at 6.00 p.m. The course deals with control and communication problems in man and machines. Those not qualified to register for an MSc degree may attend the course to improve their knowledge of the subject (Fee: £20.25 p.a.).
Application forms may be obtained from Mrs P. Smith, Electronics Dept., Chelsea College, Pulton Place, London SW6 5PR (01-736 1244, Ext. 237). (2521)

Typical NMR spectrum shown actual size, as it appears in print. All spectra are recorded on a Perkin-Elmer Hitachi R-24 permanent magnet spectrometer operating at 60 MHz.

Pre-publication offer: Save $50 on the new Aldrich 10 volume NMR collection containing over 6000 spectra

Here is a list of contents in sequence of publication.

Vol. IV
(Cat. # Z10,204-0) AROMATIC hydrocarbons, halogenated hydrocarbons, ethers & phenols.

Vol. V
(Cat. # Z10,205-9) AROMATIC alcohols, mercaptans, sulfides, amines, nitro & nitroso compounds.

Vol. VI
(Cat. # Z10,206-7) AROMATIC ketones, aldehydes, carboxylic acids & acid salts.

Vol. VII
(Cat. # Z10,207-5) AROMATIC amino acids, esters, lactones, anhydrides, acid halides, amides, nitriles & cumulated double bonds.

Vol. I
(Cat. # Z10,201-6) NON-AROMATIC hydrocarbons, halogenated hydrocarbons, alcohols, ethers, mercaptans & sulfides.

Vol. II
(Cat. # Z10,202-4) NON-AROMATIC amines, nitro & nitroso compounds, ketones, aldehydes, carboxylic acids & acid salts, & amino acids.

Vol. III
(Cat. # Z10,203-2) NON-AROMATIC esters, lactones, anhydrides, acid halides, amides, nitriles & cumulated double bonds.

Vol. VIII
(Cat. # Z10,208-3) AROMATIC 5-membered single & fused ring heterocycles.

Vol. IX
(Cat. # Z10,209-1) AROMATIC 6-membered single & fused ring heterocycles & *N*-oxides.

Vol. X
(Cat. # Z10,210-5) Sulfur-oxygen compounds, phosphorus compounds, oximes, alkynes, steroids, indole alkaloids, silanes, boranes & miscellaneous compounds.

Vol. XI
(Cat. # Z10,211-3) CUMULATIVE index, listed in alphabetical and molecular formula order.

All compounds illustrated are taken from the Aldrich Catalog/Handbook and are conveniently arranged by increasing molecular complexity and functionality.

Not since the publication of *The Aldrich Library of Infrared Spectra* has there been such a valuable compilation of information to assist the working chemist. The volumes will be published in two- to three-month intervals. An eleventh volume will contain a complete index. Volumes may be ordered individually at $15 per copy (for a total of $165) or you may subscribe to the entire series now at the prepaid, pre-publication price of $115. Then, as each volume is completed, it will be sent out automatically. This series will be immensely useful not only to users of 60MHz instruments but also to chemists and students who wish to gain familiarity with the spectral features of different classes of compounds. Because this pre-publication offer is limited, we urge you to send your order now.

Biophysics of Structure and Mechanism

Subscription Information: Volume 1 (4 issues) will appear in 1974: DM 160,—, plus postage North America: $73.80, including postage (Subscriptions are entered with prepayment only)

Sample copies available upon request. Please address Springer-Verlag, Werbeabteilung, D-1 Berlin 33, Postfach, or Springer-Verlag New York Inc., 175 Fifth Avenue, New York, NY 10010, for your copy.

Editors: H. Eisenberg, Rehovot; A. San Pietro, Bloomington, Ind.; F. Sauer, Frankfurt/M.; G. Schwarz, Basel

Managing Editor: H. Stieve, Jülich

In cooperation with an international board of advisory editors.

This new journal is designed for the publication of paper in the field of biophysics where biophysics is defined as the approach towards the understanding of biological functions through physical interpretation. The papers contribute to this objective—to explain biological functions (and facts) according to general laws of physics.

Biophysics of Structure and Mechanism publishes results of experimental and theoretical studies on the following range of subjects:

1. **Molecular structure, structural change and its biological function.** This major concern of the journal includes x-ray structure analysis; spectroscopic studies, such as NMR-, CD-, ORD-, IR-, VIS-, UV-, and ESR-studies; kinetics of reactions; interactions of molecules, etc.

2. **Transport phenomena and thermodynamics of irreversible processes applied to biological phenomena.** Since there exists a great number of journals which deal with the field of membranes, this journal will restrict itself to membrane biophysics in which emphasis is placed on the more physical approach to the membranes.

3. **Primary reactions in photosyntheses and sensory transduction.** This journal is not intended to be limited to a narrow field but rather to be a representative image of the important developments in biophysics within the broad boundaries described.

How pure is high purity water?

The right answer is critical to many laboratory test procedures. In Bulletin MB414 Millipore defines the high purity water needs of research scientists and describes systems to meet these needs. The systems are optimal combinations of purification methods to provide water of the highest possible purity and at a low cost.

MB414 is free for the asking.

MILLIPORE

Guide to authors

Nature accepts three types of communications:

● Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress.

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four displayed items (figures and tables).

● 'Matters arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. exp (*a*) is preferred to e^a if '*a*' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about as wide as a page of *Nature*. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely.

A fuller guide appeared in *Nature* (**246**, 238; 1973).

Lebesgue Integration and Measure

ALAN J. WEIR

Dr Weir's book is for the student who is meeting the Lebesque integral for the first time. It defines the integral in terms of step functions and can be immediately linked to elementary integration theory as taught in calculus courses. The more difficult concept of Lebesque measure is deduced later.

The explanations are simple and detailed, with particular stress on motivation. Over 250 exercises accompany the text and are grouped at the end of the sections to which they relate.

CAMBRIDGE TRACTS IN MATHEMATICS 68

Gibbs States on Countable Sets

CHRISTOPHER J. PRESTON

An introduction to some of the recent results and techniques in classical lattice statistical mechanics, written in the language of probability theory rather than that of physics and intended for mathematicians with little or no background in physics. The book can be used by any undergraduate student in mathematics who has a reasonable background in probability.

£3.60 net

CAMBRIDGE TRACTS IN MATHEMATICS 66

Fixed Point Theorems

D. R. SMART

The elements of fixed point theorems, an important area in the rapidly growing field of non-linear operators, are presented in this book in an easily accessible way for graduate students. Analysts will find the book valuable as the author has concentrated on those aspects of fixed point theory useful in tackling existence theorems of analysis.

£2.90 net

CAMBRIDGE TRACTS IN MATHEMATICS 65

Normal Topological Spaces

RICHARD A. ALO and HARVEY L. SHAPIRO

This is a guide for students who have studied basic topology, and intend to specialise in this large and active area of mathematics, to new and interesting advanced topics in preparation for later research work. The advantage of the book is that although **advaneed** it is less **specialised** than others at this level and will appeal to both graduate students and their teachers.

To be published shortly

£5.90 net

Computability and Logic

GEORGE S. BOOLOS and RICHARD C. JEFFREY

A textbook in logic for undergraduate and graduate students which sets out the principal theoretical results about logic and several other interesting metalogical results whose proofs are not easily obtainable elsewhere. The book covers a wide range of topics arranged in four sections: computability; logic; arithmetic; and special topics.

CAMBRIDGE CHEMISTRY TEXTS

Organic Photochemistry

J. M. COXON and B. HALTON

In this, the latest in the series of Cambridge Chemistry Texts, the authors outline the basic processes involved in organic photochemistry and discuss specific classes of photochemical reaction. The application, by Woodward and Hoffman, of the principle of conservation of orbital symmetry to concerted reactions is interwoven into the text to provide an up-to-date account of the subject for undergraduate and graduate students.

Hard covers £4.20 net
Paperback £1.90 net

Free Radical Chemistry

D. C. NONHEBEL and J. C. WALTON

A comprehensive review of the development of free radical chemistry up to the present time, presenting a description of the methods available for their study and leading up to a discussion of the important reactions. An important feature of this book is that it brings together the physical and organic branches of the subject.

A work of reference for all chemists that will be found on the shelves of research workers in universities, technical colleges and in industry.

£15.00 net

Ligand-Field Parameters

M. GERLOCH and R. C. SLADE

A descriptive review of the present state of knowledge of ligand-field theory, and particularly the ligand-field parameters used to describe the electronic properties of transition metal complexes with cubic and lower symmetries. Symmetry-based properties are discussed only to emphasise the separate roles of splitting factors and symmetry. The reader is assumed to be familiar with the usual approach to ligand-field theory and with elementary group theory.

and now . . . nuclear hypocrisy in Britain

IT has been a quite remarkable two months in which the issue of nuclear weapons testing has emerged from the shadows in which it has been lurking for ten years. The United States and Soviet Union have made noises about a further treaty; India has detonated her first device; China has fired another one (her sixteenth); France has ventured on a new series. It was only Britain of the nuclear powers who had not contributed to the drama, and now she too has obliged in characteristic fashion—by being found out.

The revelation by Mr Chapman Pincher in the *Daily Express* that there was shortly to be a British test in Nevada was greeted officially by refusals either to confirm or deny. Now Mr Wilson has announced that the test has already taken place. He must have strong feelings of *déjà vu*, as he found himself with a similar legacy from the Conservative government in 1965 when he last stopped Britain's testing activities.

Since this test surfaced as the result of a leak—and not a government orchestrated one at that—one is bound to ask whether this really is the first for nine years or whether previous testing in Nevada has been kept more effectively behind a security screen. There is really no way that anyone can find out, as testing in Nevada goes on so regularly that there would be nothing untoward to the outside world about the occasional additional test. Obviously whilst Mr Wilson was in power in the sixties there would be ideological objections, but Mr Heath was Prime Minister for nearly four years and would have no commitment to self-restraint. It seems inconceivable that it would take four years from the brakes being released until as vigorous an organisation as Aldermaston could find time to test.

The tragedy of the recent revelations is that this British obsession for secrecy in all matters of defence has rebounded so vigorously on prospects for British diplomacy. A few weeks ago *Nature*, along with almost everyone else in the West, was rebuking India for becoming a nuclear power, and the main line that most, including ourselves, pursued was that it was simply hypocritical to talk of a nuclear explosive as capable of being labelled peaceful. Britain, of course, could be particularly smug since she had renounced the provocative gesture of firing nuclear devices years ago. Our restraint was an example to the world. Now we find ourselves with much the same sort of hypocrisy on our doorsteps—a failure to be at least elementally honest about nuclear affairs; worse, a willingness to have our own test labelled, by default, as American. It is difficult to see why secrecy should extend this far. Obviously the Labour Government were not going to reveal the hot potato they were passed, but surely the Conservative government would have been in no danger in giving prior notice. The announcement of a test would barely have stirred a ripple; the discovery is bound to make waves.

The real significance of recent events, however, is that they show how inextricably intertwined are British and American nuclear interests. It is just not possible for one country to detonate explosions at another country's facility without there being such a high degree of liaison that one is bound to conclude that the two countries act as one in nuclear matters. Of course, the possession of Polaris submarines already ensures this to a large extent; the nuclear test simply brings it once more to our attention. This liaison reduces Britain's independence in the discussion of nuclear issues on a world stage to an ineffectual level. This is very unfortunate at a time when the two superpowers appear to be on the verge of agreeing between themselves on some form of nuclear test treaty.

The form most widely discussed is of a threshold agreement, restricting tests not to exceed a certain seismic magnitude. There have been strident objections to this throughout the scientific community, based on a feeling that such a treaty is easy to find loopholes in, leaves room for ambiguity and has not been given a fair debate in wide enough a community. It is possible to sense qualms in British circles too, but what hope is there of an independent and questioning line under these circumstances?

The entanglement, however, does not simply constrain Britain in nuclear matters. It is impossible to see how Atlantic and European relationships on all diplomatic matters can fail to be influenced to a degree by the nuclear commitment. It is high time that the nuclear relationship and its influence on foreign policy was looked at with great care.

100 years ago

MR. JAMES LICK, of San Francisco, California, having in the course of his life accumulated a large fortune, has recently concluded a deed by which he conveys all his property to seven persons upon trust to be applied to various worthy objects. Among these, 700,000 dols. are to be applied to the construction of a more powerful telescope than any yet made, to be erected at an observatory in California, and 300,000 dols. to found, in California, a school of the mechanical arts.

From *Nature*, **10**, 171, July 2, 1874.

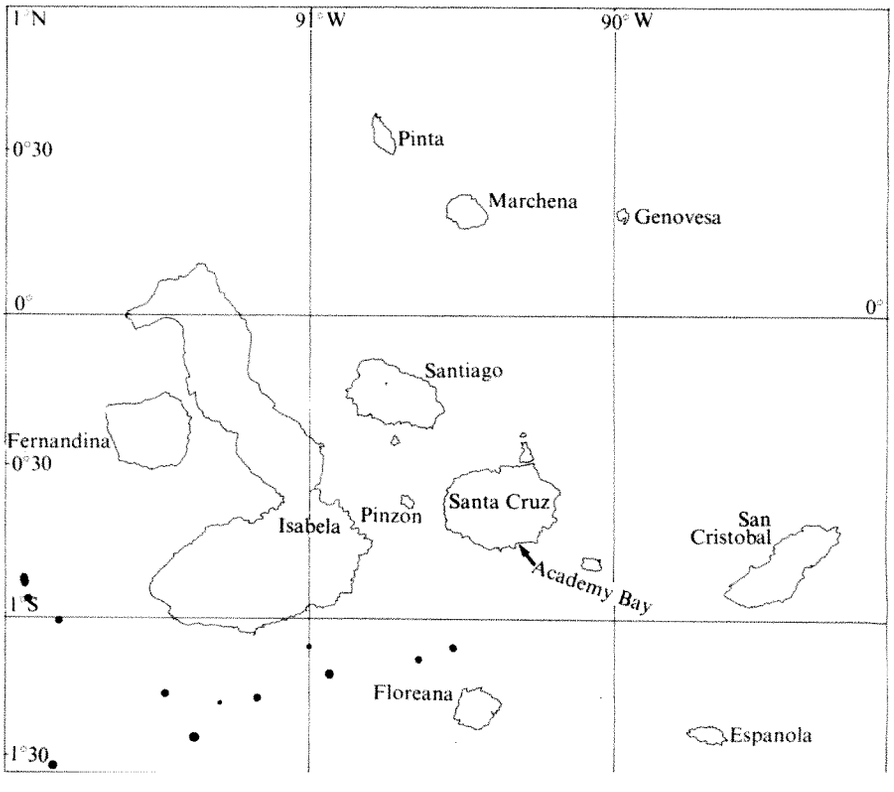
Kill a Pinta goat a day . . .

Science and conservation in the Galapagos Archipelago must swim against a fast running tide of tourism and goats. David Davies looks at the way in which the Ecuadorian Government and the Charles Darwin Foundation are trying to maintain the islands.

"I FOUND long ago that I cannot live happily without the Galapagos Islands; even if I am not there I need to know that they exist undestroyed by goats or men . . ." So wrote Peter Kramer, retiring director of the Charles Darwin Station on Santa Cruz in the Galapagos Islands in December 1973.

The Galapagos Archipelago is on the equator about 1,400 kilometres off the Ecuadorian coast. Darwin was there for 35 days in 1835, and was deeply influenced by what he saw. His field notes were dominantly geological; he was struck by the youthful volcanic nature of the rocks. It was however, the biological scene which was ultimately to have most impact on him—giant tortoises, finches (Darwin's finches) whose bills were "modified for different ends", marine iguanas, flightless cormorants and many others. By the time Darwin was writing *Origin of Species* he had absorbed much else and the effect of his stay in the Galapagos is less obvious, but in his early evolutionary writings the significance of islands is crystal clear; in 1842 he wrote on the back of a notepad "islands are the nursery of new species".

He was not the only visitor to the Galapagos. In the nineteenth century whalers would put in on their long journey from the Pacific to the American East Coast round Cape Horn, and would collect a giant tortoise to keep in the hold of the ship for later consumption. Many other ships also put in to the Galapagos, caring nothing about what species they brought in. One such import about seventy years ago was the Norwegian black rat which had such a grip on Pinzon, for example, that by 1965 no tortoises younger than thirty could be found; all tortoise hatchlings were being killed by rats. Other feral animals such as the pig have also wrought havoc on the tortoise population of various islands by eating the eggs. But the most dramatic and visible introduction has been the goat.



The local population has been in the habit of depositing goats on the more remote islands to ensure a food supply for fishing expeditions. Thus in 1958, a male and two females were left on Pinta. By 1968 the number had reached 4,000 to 5,000 and in 1971 the estimate was "not below 20,000". Hardly surprisingly, species of plants unique to the archipelago are threatened by this population on Pinta and elsewhere.

Not all the impact on the Galapagan environment has come from man's works. There are many historically active volcanoes in the west of the archipelago, and in 1968 the caldera collapse of Fernandina was the world's largest collapse in seventy years. In addition latitudinal oscillations of the Oceanic Equatorial Counter Current (the 'El Niño' phenomenon) lead to long term fluctuations in rainfall and have striking effects on the life of the islands. The most recent threat, however, has been man himself, as resident and tourist.

The population of the islands was less than 1,000 in 1960; now it is more than 4,000. Santa Cruz and San Cristobal have the most inhabitants whilst some islands, particularly the active volcanoes, are prudently uninhabited. Many of the inhabitants are farmers but an increasing number are needed to service a tourist industry which now provides for several thousand annually compared with 200 in 1969. Much of this tourism has been stimulated by the natural environment of the Galapagos and has been appropriately careful, but a growing number of private yachts visit the island on Pacific cruises and they are causing serious problems. As one scientist put it, "man has now replaced goats as the greatest threat".

The conservation issue is not simple. Although biologists would agree that there is an obvious case for the strictest of measures to preserve the islands intact, they are also the home of many Ecuadorians. In addition they occupy a strategic naval position. In two World Wars it was "he who holds the Galapagos holds the Panama Canal". There is thus a strong naval presence and in the past has even been some suspicion by the military that scientific operations have had more sinister overtones. There is thus a delicate diplomatic balance necessary in order that residents, military, tourists and nature coexist.

Ecuador has had a formal interest in Galapagan conservation since 1934 when legislation was enacted to ban the export of protected animals and the import of domestic ones. Nature reserves were also established, but

safeguards or international inspection rights (it is in fact the only reactor apart from the Canadian-Indian plant which is unsafeguarded). According to representative Melvin Price, Chairman of the Congressional Joint Committee on Atomic Energy (JCAE), it is capable of producing 8 kg of plutonium a year, which is almost enough for a crude bomb. The country is not known to have constructed a plant for separating out the plutonium from the spent fuel rods, but according to one US official, it could do so relatively easily. Thus, whatever safeguards are applied to the proposed power reactor, Israel would still be capable of joining the nuclear club if she chooses to do so. It should also be noted that neither Israel nor Egypt has ratified the Non-proliferation Treaty, although Egypt has signed it.

Be that as it may, the nuclear deals are likely to be developed as follows. Israeli and Egyptian officials have been in Washington this week to negotiate contracts for the supply of fuel to the reactors. These negotiations, ironically, have to be completed before agreement is reached on the reactor sales because the Atomic Energy Commission has set a June 30 deadline for new contracts involving the delivery of enriched uranium to foreign countries in the early 1980s. Then, a few weeks later, negotiations will begin on the sale of the reactors themselves. If agreement is eventually reached the JCAE will be informed and Congress will have 30 days in which to react. The agreement could be prevented from going into effect only if Congress passes a bill disapproving the terms under which the sale will take place. But the Bill would be subject to a possible presidential veto.

Representative Price has promised that the JCAE will give the matter a full and open review, and he has said that he "will keep (Congress) appropriately informed." of developments, during the negotiations.

But several members of Congress are dissatisfied with that arrrangement, and are attempting to give Congress veto power over any international agreement involving the export of nuclear technology. Representative Lester Wolff has already introduced a Bill into the House which will prevent the Middle East agreements from going into effect until Congress gives its express approval of the deal, and Senator William Proxmire has announced his intention to propose an amendment to the Export Administration Act when it comes before the Senate in the next few weeks, which will require that "no nuclear technology, nuclear materials, or associated equipment could be sent to any country until both houses of Congress give approval in a vote". According to a staff member of the JCAE, however, such a requirement would place a huge burden on Congress because in the past six months alone the United States has entered into some 50 separate agreements involving such transactions.

In contrast to the nuclear agreements, the scientific exchange proposals announced by President Nixon have scarcely raised a flicker of interest in the United States. As far as Egypt is concerned, Nixon and President Sadat announced in a joint communique that their two governments will establish a series of working groups to meet in the near future to prepare concrete projects and proposals for bilateral research in the fields of agriculture, "technology, research and development in scientific fields including space, with special emphasis on the exchange of scientists," and medical research.

Such activities will supplement the present limited scientific cooperation between the two countries, which is funded to the tune of about $1.5 million a year through excess US currency in Egypt (so-called PL480 funds). At this stage, the proposal is simply an agreement to cooperate and no concrete projects have been decided. Similar arrangements are proposed with Jordan and Saudi Arabia.

As for Israel, the agreement is less specific, referring only to the need for "further encouragement of the fruitful links already existing between the two countries in the scientific and technical field, including space research.

New King Coal

by Eleanor Lawrence

A "NEW ERA" for coal is forecast by the Secretary of State for Energy, Mr Eric Varley, in his introduction to the interim report of the examination into the coal industry (published by the Department of Energy) carried out jointly by the government, the National Coal Board and the mining unions.

After the depression in the British coal industry in the 1960s the report paints a much more hopeful picture of the future for the industry into the 1980s and beyond. Future demand for coal will be at least equal to if not greater than the present 130 million tons a year, predicts the report. But to satisfy this demand the industry will have to "run very fast to keep still" to the tune of £600 million in capital investment by 1985. New capacity of 42 million tons a year will be needed by 1985 to replace the coal lost by exhaustion of existing mines.

Twenty million tons of this is expected to come from new fields. The big Selby coalfield in Yorkshire will contribute up to 10 million tons a year by 1985 (it is hoped) and Mr Varley, in reply to a question in Parliament, said that the possibility of developing the rich seam of coal under Oxfordshire is being actively explored.

Nine million tons a year would come from the life extension of pits which would otherwise be quickly exhausted, and the remaining 13 million tons from new schemes at existing pits. With opencast mining a total production of 150 million tons a year is to be the ultimate target.

The upswing in the fortunes of coal follows the dramatic rise in the oil prices during the past year, which has again made coal a fuel competitive with oil. Economic conditions for a thriving industry are right for the first time in twenty years, says Mr Varley. Now the coal industry can be both competitive and commercially self-sufficient.

The electricity boards are the coal industry's main customers, taking 58% of National Coal Board (NCB) production in 1973, and the future of coal depends to a large extent on their long term policies. The Central Electricity Generating Board (CEGB) has told the committee that, providing coal remains competitive with oil, the boards will continue to take as much NCB coal as they can get. The CEGB reckons that in 1985 it will be able to burn about 90 million tons (compared with the 76 million tons it took in 1973). But the industry fears that this potential demand will not be realised unless new coal-fired generating capacity is built.

In the event the NCB has shown itself amply justified in its whole-hearted endorsement of the future of coal even when things looked blackest. The industry contracted from an output of 210 million tons and a workforce of 770,000 men in 1959 to 130 million tons and 270,000 men in 1973. The government is obviously determined not to return to the situation of the 1960s, when the increasing dependence on cheap oil led to the running down of the industry, and promise in the report that the industry shall not be at the mercy of short term fluctuations in the price of competing fuels.

Mr Varley said in Parliament last week that it would need "superhuman effort" from the industry to meet the ultimate target of 150 million tons a year. Production is down this year and two major strikes in the past three years have cast doubts on the essential condition of security of supply.

General Atomic's new fusion venture

from David Fishlock

WHILE discussions continue on the design—and location—of JET, the Joint European Tokamak, plans are ready for a start in La Jolla next month on the first of the new generation of thermonuclear fusion machines. These are the machines plasma physicists believe will demonstrate later this decade the feasibility of fusion, by reaching 'break-even'—the point at which the experiment's energy output equals the input.

Dr Tihiro Ohkawa, head of fusion research at General Atomic, the joint nuclear venture between Gulf Oil and Royal Dutch - Shell, has received approval from the United States Atomic Energy Commission for his plans for Doublet III. If all goes well by about the end of 1977 Doublet III will be ready to demonstrate plasma confinement times as long as one second.

Doublet III is the successor to a very successful experiment in magnetic containment called Doublet II, carried out by General Atomic between 1971 and 1973. Dr Ohkawa demonstrated how the plasma itself could be used as an electrical conductor to generate intense magnetic fields that remain unperturbed by the plasma. Doublet III will be a large scale version of this experiment and is expected to cost about $26 million.

A site has been chosen in the valley below General Atomic's hilltop research campus, so that the power lines supplying some 5 million amperes can conveniently be kept out of sight. The dumpling-shaped structure, some 13 feet tall and 18 feet in diameter, is expected to take 3–5 years to complete. Meanwhile, to assist the designers Doublet II has been stripped down and is now being rebuilt as Doublet IIA, with magnetic facilities for fine tuning the plasma configuration.

In the late 1960s, when the physics of fusion was still in chaos, Dr Ohkawa's fusion research group suffered far more severely than the British Culham Laboratory. After Texan utilities withdrew their support his group numbered no more than seven. But, encouraged by Dr C. L. Rickard, vice-president in charge of advanced systems development, Ohkawa rebuilt confidence among sponsors. Today he can boast the largest fusion team in the private sector anywhere in the world. It numbers 80 and this year will spend about $7 million. Next year it will number 120.

It draws these funds from three sources—the company, a group of electrical utility sponsors and the United States Atomic Energy Commission. Of this year's research budget, about $2 million is being spent on plasma physics, $4 million on large fusions systems (mostly Doublet IIA) and the remaining $1 million on technology for the fusion reactor. But this last sector is expected to grow quickly, so that by 1980 it will be at least the size of the other two parts of the programme.

Already a conceptual design is taking shape of a candidate for the prototype fusion reactor which the Atomic Energy Commission hopes to start building in 1976. General Atomic is thinking in terms of a reactor based on Doublet III that will 'piggyback' on the company's experience with helium-cooled fission reactors. Instead of using a liquid-metal-cooled system, as is usually proposed for extracting heat from a fusion reaction, it plans to use helium as the coolant and to drive gas turbines directly with the hot but inactive gas. For the present, therefore, Dr Ohkawa is confining his forays into fusion reactor technology to work on a ceramic torus—of silicon carbide and carbon—in which the plasma will be confined.

Death-blow dealt to Moscow seminar

from Vera Rich

Slepak : leading activist

INTENSIFIED pressure on the part of the Soviet authorities would seem to have dealt a death-blow to the Moscow 'underground' seminar on "Collective Phenomena and the Applications of Physics to Other Fields of Science" scheduled for July 1-5, 1974. A wave of arrests in the Soviet Union of Jewish dissidents, supposedly in connection with security arrangements for the Nixon visit, coupled with the blocking of visa applications from intending foreign participants, almost certainly mean that the seminar can no longer take place as originally envisaged.

The campaign began, apparently, on Wednesday, June 19, with an attempt to arrest an electronics engineer, Vladimir Slepak, who, although not a member of the Seminar Programme Committee, is a leading Jewish activist in the Soviet Union. Slepak apparently resisted arrest by barricading himself into his apartment; on Friday, however, the police broke in with crowbars. It is reported that when his fifteen-year-old son Leonid attempted to contact western journalists by telephone, the KGB intervened.

On the same day, Committee Member Viktor Brailovskii, in hiding to avoid forcible conscription, failed to keep a prearranged telephone contact with the international organisers of the seminar, while a telephone call to Tanya Levich (the wife of committee member Venyamin Levich) was established and cut off three times so that no message could be conveyed. It now seems that Lerner, Brailovskii and also committee members Mark Azbel, Aleksandr Lunts and Aleksandr Voronel were arrested on Friday or Saturday. Voronel, whose Moscow apartment was to have been the venue of the seminar, was arrested at the home of a friend. He is reported to have "given himself up" to the police—in view of the details of Slepak's arrest, however, this probably means no more than that he opened the door to them. Since all contacts between the dissidents and the outside world have now been broken, it is quite possible that this list of arrests is by no means complete.

Simultaneously with the news of the arrests, the foreign "participants" learned that they themselves would not be able to travel to Moscow. Some 40 scientists from the United States (including seven Nobel Prize winners) have been refused visas. Similar refusals are reported from Israel and France. The British contingent, for whom more details are available, reveal an interesting picture of blocking tactics. Those intending to travel alone were told, on submitting their applications, that they must provide an official invitation from some recognised scientific organisation in the Soviet Union (which, of course, they were unable to do). Since then they have heard no more of their applications. The others, who planned to travel as a group, have not met a definite refusal; but since the last date by which the travel agents needed visa clearance in order to complete the necessary arrangements has now passed, this amounts to *de facto* refusal.

Asked to comment on the situation Dr Norman Chigier of the University of Sheffield, one of the three International Secretaries of the Seminar, observed: "It appears that the Soviet authorities are determined to destroy the seminar".

Egg collector collected

Wood Sandpiper: collected

CITIZENS of the United States are entitled under their constitution to bear arms, and they believe in using them. In addition to shooting public figures and wild game, they are also accustomed to collect any rarities they encounter "for scientific purposes". There is a conspiracy of silence over this in North America, where for example the senior ornithological journal has refused to publish any comments on reports that specimens of the first Little Gulls *Larus minutus* and Wood Sandpipers *Tringa glareola* found nesting in North America were promptly collected despite the fact that they are easily recognised and that there was already ample material available. Even the supposedly militant Audubon Societies have said nothing about the situation. There has, however, been a growing chorus of complaint where the same policies have been followed abroad. Many of the atrocities have been perpetrated by young and inexperienced people, brought up in an unhealthy tradition by their seniors who tend to escape the blame, so it is worthy of note that one Daniel has at least been brought to judgement in his own courts.

For several months now there has been an excited twittering in international ornithological circles as the news went round that Professor Charles Sibley, formerly of Cornell University and now of Yale University, who was awarded the American Ornothologists' Union's Brewster Memorial Award for the electrophoretic analysis of egg-white proteins in 1971 and subsequently elected a Vice-President, has been found participating in the international egg trade. It seems that by a skilful piece of deduction Richard Porter of the British Royal Society for the Protection of Birds, concluded that a local egg collector must be dealing with foreign parts, located allegedly incriminating correspondence with Professor Sibley and referred it to the American authorities. Professor Sibley's files at Yale were then inspected, with the result that on May 20 he was fined $3,000 under the Lacey Act for six cases of "illegally importing bird parts taken abroad in violation of foreign wild life laws", five of them in Britain.

The situation is made worse by the fact that for at least fifteen years the British Home Office Advisory Committees had already been stretching the law to the limit to enable Professor Sibley to obtain material legally, and many British ornithologists had been assisting him with this. He justified his decision to exceed his allocation by telling the British *Sunday Times* (June 16) that it was an insult to his scientific standing imposed by emotional bird conservation groups with little knowledge of bird population dynamics, which he felt entitled to ignore because "the idea that taking a few eggs could endanger a species is the most ridiculous thing you could imagine . . . I say 'fine, we'll pay the penalty, but you are going to have to listen to the real experts, because you are not the real experts' ".

The British Home Office Advisory Committees consist of people of a most unemotional sort who are internationally recognised to have made more important contributions to the study of population dyanmics than Professor Sibley. They must have been watching the amount of material that he had already received through legal means, which is known to have been large, rather carefully, and it would be interesting to know where Professor Sibley expects to find greater "experts". It is surprising to find a person in such a responsible position at such a distinguished institution first behaving in such a way and then indulging in such an outburst when he was found out. If senior people behave like this, it is hardly surprising that the conduct of some junior American ornithologists is not all it should be. It is good to see the American authorities take the first steps towards putting their house in order. But there is still bigger game in the woods.—From W. R. P. Bourne.

Smallpox report

THE British government has accepted in principle the main recommendations contained in the report of a committee which enquired into causes of the London smallpox outbreak of 1973, when two people died and widespread disruption was caused as vaccination was demanded for four to five millions.

The circumstances leading to the appointment of a committee of enquiry were that a graduate laboratory technician employed at the London School of Hygiene and Tropical Medicine was admitted to hospital on March 16th suffering from suspected meningitis or glandular fever. In fact she had contracted smallpox, and after being placed in an open ward at St. Mary's Hospital, Harrow Road, she came into contact not only with other patients but with two visitors who subsequently contracted the disease and died.

There was serious disquiet that a laboratory worker could have become infected while working in the laboratory; that having become infected, she could spend a week in the general ward while the disease remained undiagnosed; and further, that even after a provisional diagnosis of smallpox, another twelve days elapsed before the visitors were traced, by which time it was too late to save their lives.

The committee found, among other things, that inadequate safety measures were in force at the London School of Hygiene and Tropical Medicine, where the technician was infected while watching the harvesting of pox virus. The pox virus laboratory was said to be old fashioned, poorly decorated, overcrowded and dirty — conditions which, said the report, led to a lowering of safety standards.

Lethal smallpox virus samples were stored in a corridor in an unlocked deep-freeze, workers from other laboratories passed to and fro, using equipment housed in the pox virus lab, and there was an inadequate immunisation policy in the School's Department of Microbiology. Each unit within the department was left to make its own arrangements in relation to its own hazards.

The report recommended the establishment of a permanent committee to draw up and enforce a code of practice for work on pathogens constituting a major threat to public health; the appointment of a safety officer at the School (already implemented); and, since many of the shortcomings resulted from cash shortages in the first place, financial aid to implement the safety proposals.

Failure to trace contacts in the case were caused by a catalogue of administrative errors, coupled with the fact that no one realised the urgency of the situation, says the report, recommending the appointment of regional specialists to supervise control of outbreaks, consideration of compulsory isolation of contracts, and better diagnostic guides for doctors.

correspondence

Unreal Science

SIR,—As a qualified and practising scientist I wish to dissociate myself from your editorial of April 12. You allude to Geller and Velikovsky with terms like "nonsenses", "beliefs beyond science", and "pseudo-scientific ideas", and contrast these with "real science" and "science based on conventional ideas about the way a scientific investigation should proceed", and you declare that "scientists want to fight this distressing drift from the scientific way of thinking".

History is littered with ideas shown to be false by people bold enough to question their contemporary conventional science, often in the face of personal ridicule and even persecution.

Presumably you class Einstein's relativity theory with 'real' science, yet to back his theory Einstein makes a couple of postulates, not yet proven, whilst the unreal Velikovsky quotes source after source and fact after fact to back his. Where Velikovsky leaps eagerly into the jig-saw puzzle of the past and fits piece after piece together (rather unscientifically perhaps, but incorrectly . . . ?) Einstein treads warily (and of course scientifically) through his mathematical maze, and deigns to emerge into the real world only at the end to explain Mercury's perihelion drift and to predict the deflection of light by the Sun. But wasn't there someone recently who found that the Sun was a little flatter than was previously thought which could account for half that drift (doesn't that make Einstein at least half wrong?), and isn't there someone else suggesting there's a planet, Vulcan, in there somewhere, or even maybe a whole asteroid belt? And just for one careless moment suppose that Velikovsky were right . . . no, of course —much too unscientific!

I am not saying Einstein is wrong and Velikovsky right, but I believe both men's theories worthy of serious consideration. You say "*Nature* has a responsibility (that) guides us in the choice of papers for publication". You have a right and a duty to edit, but that statement smacks of censorship. Velikovsky encountered censorship. More recently Dingle has met similar problems for daring to question Einstein.

I am not young nor am I by any means a pseudo-scientist, nor are a number of colleagues who share my opinion. I want no part in any science which operates with a closed mind, and I will encourage the young, and old, to drift from such a way of thinking, though I hardly need to. Your own editorial will do that well enough by itself.

P. WARLOW

Southminster, Essex, UK

Cancer research

SIR,—Your correspondent Brian Ford comments (*Nature*, May 24) on the abundance of data and paucity of concepts in cancer research. A cursory survey of the literature strongly supports this point.

For example, 10 randomly chosen issues of *Excerpta Medica—Cancer* were found to cite about four thousand papers, of which a total of nine were classified as Theories of Carcinogenesis. It is as though 99.8% of the time taken to solve a jig-saw puzzle went on gathering heaps of pieces and 0.2% went on fitting the pieces together. This imbalance conflicts with the widespread belief that cancer research needs "more facts and fewer theories". The opposite appears to be the case.

Yours faithfully,

T. E. WHELDON

Department of Clinical Physics and Bioengineering,

Geology ⊃ geophysics?

SIR,—The President of the Geological Society of London, the Director of the Institute of Geological Sciences and Professor P. Allen have informed us[1] "that geophysics is a necessary and important part of geology" and in case the reader misses the point they say it again " . . . of earth science, that is of geology." That a present and past—and one hopes future—president of the oldest Geological Society in the world should so write is doubtless a Freudian slip, as earlier this century the society refused to take geophysics under its wing, this important task being faithfully discharged since then by the Royal Astronomical Society to the mystery of our friends abroad. In the Cambridge Tripos Part II twenty years ago the question was set: "Geophysics dots the i's and crosses the t's of geology. Comment." I seem to recall that Professor Allen was an examiner. Perhaps those who simply answered "But, of course" qualified for firsts!

I have always worked, as have your correspondents, for more understanding and dialogue between geophysicists and geologists, but also between geophysicists and astronomers and physicists: problems of the Earth's rotation, Earth and planetary magnetic and gravitational fields, solid state physics of interiors, lunar and planetary formation are of more interest to the latter groups than to geologists. Geologists on both sides of the Atlantic who suppose—perhaps understandably as the highways of earth science are presently congested by careering bandwagons—that continental drift, seafloor spreading, plate tectonics and plumes is the whole of geophysics might do well to read again Sir Harold Jeffreys's *The Earth* or study Professor A. H. Cook's *Physics of the Earth and Planets.*

As Sir Peter Kent is also Chairman of the Natural Environment Research Council (NERC), it seems desirable to emphasise that geophysics is a discipline in its own right separate from —and one might add older than— geology. The NERC awards of research studentships for the Earth Sciences seem to me to be seriously overweighted[2] at present in favour of geology as against geophysics by about 7:1. This disparity does not reflect the relative need for highly trained people in these two disciplines nor the present intellectual challenges in the two subjects: it reflects the fact that there are some 45 departments of geology in British Universities.

Thus, as Chairman of the Royal Society committee which launched the European Geophysical Society, I welcome the 1975 "Europe from crust to core" meeting as a further step in European scientific cooperation. I hope that the formation of a 'Pan-European Society of Earth Scientists' (as distinct from a European geological society) is not seriously mooted if only on logistic grounds. Geophysicists interested in geological problems will surely come, as I hope to myself, to Reading and geologists concerned especially with tectonics will continue to join us at the European Geophysical Society's annual meetings.

Yours faithfully,

S. K. RUNCORN

University of Newcastle upon Tyne

news and views

Testing for carcinogens and mutagens

It has been known since the work of Pott in the eighteenth century that certain forms of cancer are associated with certain occupations and it is now generally accepted that the disease can be and is caused by chemicals in the environment. The number of chemicals that have been shown experimentally to induce cancer in laboratory animals is very large and constantly increasing but the numbers known with reasonable certainty to be active in human beings is very much smaller. Recognised human carcinogens were listed by Hueper in 1971 (*Health Phys.*, **21**, 689–707; 1971) and included asbestos and some metals, several aromatic amines, various tar and pitch products and mustard gas. Since then adenocarcinomas of the vagina in young women and girls has been linked with exposure to diethylstilboestrol *in utero* following therapeutic administration of the compound to their mothers during pregnancy (Herbst *et al.*, *New Engl. J. Med.*, **284**, 878–881; 1971), the occurrence of benign tumours of the liver has been reported in women taking oral steroidal contraceptives (Baum *et al.*, *Lancet*, ii, 926–929; 1973) and, more recently of all, angiosarcoma of the liver has been found in men exposed to vinyl chloride during the manufacture of polyvinylchloride (PVC) one of the most extensively used plastic materials (*Br. Med J.*, **1**, 590–591; 1973).

It is highly significant that these human tumours are all exceedingly rare and therefore the occurrence of even quite small numbers of cases led to the suspicion of an environmental factor in their causation. It is very unlikely indeed that an environmentally-caused increase in a common human tumour would be so readily detected, for example cancer of the lung or colon in the United Kingdom. The realisation that many chemicals are mutagenic has been relatively recent and the problems of detection of altered mutation rates in human populations are formidable. It is therefore of the utmost importance to develop reliable tests for carcinogenicity and mutagenicity of environmental chemicals.

There is substantial agreement on methods for conventional long-term carcinogenicity tests in rodents and these provide the best available means for assessment of possible carcinogenic hazard to man. They are, however, very expensive and require at least 3 years for completion. Methods for mutagenicity testing in mammals are less well established. The specific locus test in the mouse can only be applied to a limited number of chemicals because it requires very large numbers of animals and it is extremely expensive. The dominant-lethal test and cytogenetic analysis *in vivo* require far fewer animals but they are still expensive and time consuming. There is thus a very real need for simpler and less costly tests for carcinogens and mutagens in the environment and much effort is currently being directed towards the development of *in vitro* test systems using cultured cells and microorganisms. Although such tests are unlikely to give conclusive results they may provide valuable information for the assignment of priorities for more definitive test procedures.

The molecular mechanisms of chemical carcinogenesis are not understood but it is now clear that most of the chemicals that cause cancer (precarcinogens) do so as a result of metabolic conversion into more carcinogenic substances (proximate carcinogens) and finally to chemically reactive electrophilic products (ultimate carcinogens) which react with nucleic acids, proteins and other cellular components and which are also mutagenic (Miller, *Cancer Res.*, **39**, 559–576; 1970). Without assuming the same mechanism for chemical carcinogenesis and mutagenesis it may be concluded therefore that demonstration of mutagenic activity in a chemical should give warning of its possible carcinogenicity.

Apart from *Drosophila*, the organisms commonly used in research on chemical mutagenesis including *Escherichia coli*, *Salmonella typhimurium*, *Neurospora* and *Saccharomyces*, do not contain the mixed function oxidases necessary for activation of precarcinogens and premutagens and do not therefore undergo mutation after exposure to these chemicals. This difficulty has been overcome in the host-mediated assay (Gabridge and Legator, *Proc. Soc. exp. Biol. Med.*, **130**, 831–834; 1969) in which test microorganisms are injected into the peritoneal cavity or elsewhere in mammals, usually rodents, and the putative mutagen is given by another route. The organisms are recovered after an interval and scored for mutants. Several chemicals that are inactive by direct application to the organisms become active in this assay, which makes use of the microsomal or other enzymes of the host. A logical extension of this procedure was to use an *in vitro* system in which the test compound is incubated with mammalian liver microsomes in the presence of the necessary co-factors and suitable indicator microorganisms. For example, dimethylnitrosamine was actively mutagenic when incubated under such conditions with mouse liver microsomes (Malling, *Mutation Res.*, **13**, 425–429; 1971) and human liver preparations have recently been shown to be similarly active (Czygan *et al.*, *J. natn. Cancer Inst.*, **51**, 1761–1764; 1973). Although these *in vitro* methods are relatively easy and quick they still require appreciable time and experimental skill and the process has been simplified further by Ames and his colleagues (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 2281–2285; 1973) who have incorporated a post-mitochondrial liver homogenate into the agar plate used for culture of the test organisms. Using this procedure several chemical carcinogens, mainly planar aromatic compounds, were shown to be frame-shift mutagens. Further work with more and different types of carcinogens is needed before the value of the Ames procedure for large-scale screening of environmental chemicals can be adequately assessed. If it proves sufficiently sensitive and reliable it should, by virtue of its simplicity and cheapness, provide a valuable addition to currently available tests.

More recently Durston and Ames (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 737–741; 1974) have used the combined agar plate-microsome method for the detection of mutagens in urine and the communication by Commoner, Vithayathil, and Henry on page 850 of this issue of *Nature*, reports similar experiments. Both groups of workers investigated the urine of rats given the potent carcinogen 2-acetylaminofluorene (AAF) and Commoner *et al.* also studied *p*-dimethylaminoazobenzene (DAB). Both groups found mutagenically active metabolites in the urine of rats treated with AAF and the activity was increased after addition of

β-glucuronidase. Commoner *et al.* also found that the urine from DAB-treated animals contained active mutagenic components but only after treatment with β-glucuronidase and take-diastase; this is of interest because Ames *et al.* had previously reported that DAB itself was not mutagenic after exposure to liver homogenates *in vitro*. Clearly many more carcinogens and other compounds must be tested in this system before it can be properly evaluated. Nevertheless, as the authors point out, the test system for urinary mutagens could readily be included in toxicity studies on laboratory animals and it could also be used to screen the urine of human populations for the presence of conjugated and unconjugated mutagens. In this way, the prior ingestion of carcinogens and mutagens in the diet and from other environmental sources might be revealed.

P. N. MAGEE

Destruction of atmospheric ozone?

THE Earth's atmosphere is extremely effective in filtering out that part of the Sun's ultraviolet radiation which is harmful to life, that is, radiation with wavelengths below about 300 nm. Ultraviolet radiation with shorter wavelengths, below about 200 nm, is absorbed by molecular oxygen, O_2. The rarefied, but nevertheless strongly absorbing, ozone molecule, O_3, traps the remaining longer wavelength ultraviolet radiation up to about 290 nm, a region in which O_2 is virtually transparent. The main ozone layer extends very roughly between altitudes of 15–50 km above the Earth's surface.

As severe radiation damage to the surface cells of plant and animals is causd by intense ultraviolet light at wavelengths of less than 300 nm, changes in the very low atmospheric ozone concentrations, which filter solar radiation, are of vital concern. Normally, atmospheric ozone concentrations are held in rough balance between the rates of production and destruction of O_3. Ozone is produced by the photochemical dissociation of O_2, followed by recombination of the oxygen atoms with O_2 in the presence of a third gas molecule M,

$$O_2 + h\nu \rightarrow O + O$$
$$O + O_2 + M \rightarrow O_3 + M$$

The destruction of O_3 can occur through its reaction with O atoms, or alternatively, by reaction with nitric oxide, NO, which is known to be a trace constituent even of unpolluted atmospheres.

Ozone is a highly reactive molecule, and it has been suggested recently that artificial injection of certain chemical species into the stratosphere may diminish the ambient ozone concentrations by increasing its rate of destruction, thus upsetting the natural ozone balance. The consequently increased flux of far ultraviolet light incident on the Earth's surface would obviously have far reaching, deleterious consequences.

Particular attention has been focused on the possible role of nitric oxide (or equivalent nitrogen oxides, often referred to generally as NO_x) in affecting stratospheric ozone. Nitric oxide, which is a minor product of combustion processes, is emitted into the stratosphere by high flying aircraft and by other aerospace vehicles. Johnston, at Berkeley, has proposed the following two-step catalytic cycle for ozone destruction by added nitric oxide:

$$NO + O_3 \rightarrow NO_2 + O_2 \quad (1)$$
$$O + NO_2 \rightarrow NO + O_2 \quad (2)$$

Thus, reaction (1) and (2) together consume O_3 and O atoms, and provide a mechanism for recycling NO. The rates of reactions (1) and (2) are now well known, and so there is no doubt that sufficient quantities of nitric oxide, if well mixed with the stratospheric atmosphere, could consume ozone in this way. The exact concentrations of the relevant atmospheric species are not well enough known, however, nor are the effects of the local injection of NO_x—as opposed to the addition of 'well mixed NO_x'—clear. There is no general agreement about whether stratospheric ozone levels will be affected by NO_x injected into the atmosphere by known plans for fleets of supersonic aircraft. Nevertheless, an appreciation of the possibility of a perturbation of the ozone cycle by for example, nitric oxide, is clearly most important. Indeed, concern has been expressed in the British press, following Pittock's report (*Nature*, **249**, 641; 1974) of a significant downward trend (since June, 1965) in atmospheric ozone concentrations at altitudes up to 25 km above the Earth's surface. It remains to be seen whether or not Pittock's conclusion, based on carefully executed, but difficult, experiments, is confirmed by other workers. At any rate, there is growing awareness of the importance of the possibility that the natural ozone cycle may be upset by atmospheric pollutants.

That awareness led recently to the discussion of a possible chlorine oxide, ClO_x, cycle, based on two steps involving chlorine atoms, Cl, and the chlorine monoxide free radical, ClO:

$$Cl + O_3 \rightarrow ClO + O_2 \quad (3)$$
$$ClO + O \rightarrow Cl + O_2 \quad (4)$$

Stolarski and Cicerone, elsewhere, and Molina and Rowland, on page 810 of this issue of *Nature*, consider this cycle, and suggest that Cl atoms are formed in the stratosphere. The suggested methods of formation include the photochemical dissociation of HCl from rocket exhaust gases, and of freons which diffuse upwards from the Earth's surface. Freons, compounds which contain only carbon, chlorine and fluorine, are manufactured extensively as aerosol propellants and refrigerants. Molina and Rowland, working at the University of California at Irvine, consider that the freons CF_2Cl_2 and $CFCl_3$ have a long residence time in the lower atmosphere. This would allow their concentrations to build up, without any obvious sinks for their removal. Rough calculations suggest that virtually all of the freons ever manufactured now remain in the atmosphere. The upward diffusion of freons, followed by photochemical dissociation, could result in chlorine atoms at stratospheric altitudes.

Watson and I at Queen Mary College, University of London, have determined recently the rates of several of the relevant chemical reactions involving Cl atoms, and O_3 and ClO radicals. Molina and Rowland, using these and other results, point out that, at stratospheric temperatures, the attack of ClO on O (reaction (4)) is six times as rapid as that of NO_2 on O (reaction (2)). Consequently, under some conditions, the Cl/ClO cycle can be considerably more efficient than the NO/NO_2 cycle in the catalytic conversion of $O_3 + O$ to $O_2 + O_2$. At some altitudes, a mixed NO_x — ClO_x cycle may also be important:

$$Cl + O_3 \rightarrow ClO + O_2$$
$$NO + ClO \rightarrow Cl + NO_2$$
$$O + NO_2 \rightarrow NO + O_2$$

Molina and Rowland conclude that the Earth's atmosphere has only a finite capacity for absorbing chlorine atoms without important consequences. According to their view, the present understanding of atmospheric chlorine chemistry suggests that this absorptive capacity may be insufficient even to cope with the number of Cl atoms equivalent to the quantities of freons at present introduced into the atmosphere on a world-wide scale. More accurate estimates of the absorption capacity are desirable, and no account can be taken of possible heterogeneous reaction between Cl atoms and particulate matter in the stratosphere. If the conclusions of Molina and Rowland are correct, then the effects of the stratospheric photodissociation of CF_2Cl_2 and $CFCl_3$ could not be removed immediately even if no more freons were introduced at ground level. That is because of the postulated long residence time of these species in the lower atmosphere.

The inevitably approximate nature of this type of calculation, and the far reaching assumptions required, should be borne in mind. Discussions such as that of Molina and Rowland, however, serve a most useful purpose in initiating discussion of a new aspect of atmospheric ozone. It is reassuring that interest in these and related problems is being taken by the US Department of Transportation, in its support of the Climatic Impact Assessment Program, under the auspices of which several valuable discussion documents are being issued.

It is conceivable that sulphur dioxide, emitted in relatively large quantities during the combustion of many natural hydrocarbon oils, such as aviation fuel, might also affect ozone concentrations by the photochemical dissociation of SO_2 to SO + O, followed by the reaction of SO with O_3, which has a rate comparable to that of NO with O_3.

This possibility, which requires further consideration, is raised in order to highlight the fragility of the ozone layer and the consequent need for thorough knowledge of the mechanisms and rates of chemical reactions involving ozone.

M. A. A. CLYNE

Phosphorus and the eutrophication problem

SCHINDLER of the Freshwater Institute, Winnipeg, has described in *Science* (**184**, 897–898; 1974) the effects on the growth of planktonic algae of fertilising small, unproductive Canadian lakes with compounds of phosphorus, nitrogen and carbon. If nitrogen or carbon were added there was no marked change in the phytoplankton. If phosphorus was added as well or by itself, there were large increases in phytoplankton. When the additions of phosphorus were discontinued the phytoplankton soon returned to the pre-fertilisation levels. Hence Schindler concludes that a large decrease in the phosphorus content of sewage effluents is the essential remedy for the over-enrichment of waters by man or, as it is called, cultural eutrophication. Polyphosphates in detergents should be banned since they form some 50% of sewage phosphorus (somewhat less in Britain). He agrees with those people who advocate the chemical treatment of sewage to remove a substantial amount of all waste phosphorus. But rapid action is needed and the removal of polyphosphates from detergents will meet this need.

Nearly all limnologists who have investigated the problem will agree with Schindler that phosphorus is a major cause of eutrophication. He refers to several lakes which have benefited from the removal of sewage effluents but it is less clear whether the removal of detergent phosphorus alone would have prevented undesirable eutrophication. Some action has been taken. Canada has prohibited the sale of detergents containing more than 2.2% of phosphorus and some American States have passed similar legislation (see Schindler's article); others will remove phosphorus by sewage treatment.

If polyphosphates are to be removed from detergents, in which they play a vital part, what is to replace them? At present there is no generally agreed answer. In Canada nitrilotriacetic acid (NTA) is a permitted alternative. A governmental warning against its use, has, however, been issued in the United States (see statements by Environmental Protection Agency Administrator and Surgeon General (December 18, 1970) and by Chairman, Committee on Public Works, US Senate (December 19, 1970)). As a result substances such as washing soda and sodium silicate have been used and the detergents containing them are said to be of poor quality, as may be expected. Experience of the world-wide use of several organic compounds suggests that extensive and intensive tests are necessary before they are accepted as safe. Phosphates, though bad for eutrophication are otherwise harmless. One must also realise that any increased cost of a replacement will be passed on to the consumer. It seems therefore that there are arguments for and against Schindler's viewpoint.

European experience supports Schindler's view that phosphates are the commonest major cause of cultural eutrophication and that nitrogenous substances are the next most important cause (Vollenweider, OECD Report DAS/CSI/68.27; 1968). Observations for more than 30 years and experiments with large enclosures in the English Lake District (Lund, *Proc. R. Soc.*, **B180**, 371–382; 1972; *Verh. int. Verein. theor. angew. Limnol.*, **18**, 71–77; 1972 and unpublished data) have also shown that phosphorus is an important factor in eutrophication, though it is an over-simplification to blame everything on one element. The same is likely to be true in other British waters.

The UK Standing Committee on Synthetic Detergents (12th Progress Report, HMSO; 1971) is against the present use of NTA and does not consider that phosphorus removal is as yet justified. Nevertheless its reduction from sewage before it enters the already eutrophic Lough Neagh, Northern Ireland has been advocated (Wood and Gibson, *Water Res.*, **7**, 173–187; 1973). Schindler says that the removal of phosphorus from sewage "while fine in principle . . . will take several years to implement to any effective degree, considering the time lags and uncertainty inevitable in financing, planning and constructing such facilities". Sweden and Switzerland, however, have gone ahead vigorously with just such a scheme; other countries are doing so or preparing to do so to various extents. In Sweden, in particular, it seems that an added gain is a general improvement in the final effluent.

The eutrophication problem is not the same everywhere. It is doubtful whether the best remedy for one lake or lake region is the best for all. Phosphate enrichment may produce unwanted changes in one lake but will not do so in other lakes. Moreover, opinions differ about which substances are the most harmful. It seems reasonable that each lake or lake area should be considered separately, bearing in mind the general, though still imperfect, knowledge of eutrophication. Then it can be decided whether remedial measures are necessary, what they might be, whether they are acceptable on economic or other grounds and whether legislation is necessary to implement them.

J. W. G. LUND

Survival of the Teesdale rarities

from Peter D. Moore
Plant Ecology Correspondent

RARITY is an attribute which makes an organism peculiarly attractive to mankind, even to biologists. When many rare organisms are gathered together in one place, it is inevitable that biological attention should be focused on that spot. In the British Isles there is no better example of this than the rare plants of Teesdale, especially since they have been threatened and partially obliterated by the development of the Cow Green Reservoir. One good result of this incident is the burst of research activity which it has stimulated, partly as a result of the finance generated by the setting up of the ICI Teesdale Trust Fund, a kind of sad consolation for depleted biological resources.

The major biological problem presented by Teesdale is a phytogeographical one, namely the explanation of the surprising distribution patterns of some of the rarities, such as *Gentiana verna*, *Minuartia stricta*, *Tofieldia pusilla* and *Kobresia simpliciuscula*. In 1956, Pigott (*J. Ecol.*, **44**, 545) presented a detailed survey of the plant communities in Teesdale and suggested possible explanations for the unusual assemblages of species found there. Following the arguments of Godwin (*J. Ecol.*, **37**, 140; 1949), he considered that these communities were relicts of late-glacial vegetation which had survived because of the poor growth of forest in the area during the postglacial climatic optimum. Factors such as severity of climate and instability of soil may have assisted such survival.

Direct evidence of postglacial survival has been found in the local peat deposits, where plant fragments and pollen grains are preserved (Squires, *Nature*, **229**, 43; 1971 and more recently Turner *et al.*, *Phil. Trans. R. Soc.*, **B265**, 327; 1973). Peat deposits, some dating back to the late-Devensian (last glacial) period, show that light demanding plant species have been present in some quantity throughout the Flandrian (postglacial) period. Woodland cover can never have been complete, therefore, and the refugium hypothesis of Pigott gains support. Furthermore, some of the rare and uncommon plants (such as *Gentiana verna*, *Dryas octopetala*, *Polemonium caeruleum* and *Polygonum viviparum*) have a fairly continuous pollen record, indicative of postglacial survival. Many of the other rare plants, however, cannot be identified to the level of species on the basis of their pollen so that evidence for them is still lacking.

An alternative approach to the problem is the study of the ecophysiology of the rare plants. Arnold (*New Phytol.*, **73**, 333; 1974) has examined the growth of seedlings of two Teesdale plants, *Kobresia simpliciuscula* and *Plantago maritima*. Seeds of these species were germinated at 18° C and the seedlings were grown at 10°, 14° and 18° C at a light intensity of 60 W m^{-2}. Records were kept of leaf length, width and number and net assimilation rate. Both species grew faster in all respects at higher temperatures but, in the case of *Kobresia*, there was a marked increase in growth at 18° C when compared with that at 14° C. Mean summer temperatures in Teesdale are between 10° C and 14° C; temperatures of 18° C were exceeded on only about 3% of summer days. Arnold remarks that *Kobresia* would be favoured by a warmer environment and she finds difficulty in explaining its occurrence at Teesdale in terms of its temperature response. The answer seems to be that temperature response is not an important parameter in this situation. The experiments demonstrate that these species are living suboptimally in Teesdale as far as temperature is concerned, but this is not surprising. The survival of such plants is due to their ability to maintain a positive growth rate where many other more robust species (including trees) fail to do so. The relevance of these temperature response data, if indeed they are relevant, will only be appreciated when further figures are available from the potential competitors of the Teesdale rarities.

Genes for N_2 fixation on the move again

from a Correspondent

Two years ago Dixon and Postgate reported (*Nature*, **237**, 102; 1972) their success in transferring nitrogen-fixing ability from a N_2-fixing strain of *Klebsiella pneumonia* to the common colon bacteria *Escherichia coli*. Greater complications in using plant nodule bacteria from the genus *Rhizobium* as donors of nitrogen-fixing ability were anticipated since the presence of N_2-fixing activity in *Rhizobium* cannot be shown in laboratory cultures, and the genus *Rhizobium* lacks an effective genetic system for mobilising genes. This difficulty now seems to have been overcome by Dunican and Tierney of University College, Galway (*Biochem. biophys. Res. Commun.*, **57**, 62; 1974) who have been able to transform a derepressed antibiotic resistance transfer factor into *R. trifolii*. This work greatly increases the possibility of mobilising *Rhizobium* genes since this same factor is known to mobilise with an appreciable frequency genes in other bacterial systems. With this R factor present the *Rhizobium* acted as if it had had a sex factor and transferred the ability to fix nitrogen when mated with a non-fixing strain, *Klebsiella aerogenes*. Hybrids capable of fixing nitrogen, measured by the acetylene reduction technique, oc-

curred with a frequency of 10^{-7} or higher. Some of these colonies retained the ability to fix nitrogen when subcultured and in these cases maintenance of the R factor was not essential for retention of N_2-fixing ability. Not unexpectedly, the N_2-fixing *Klebsiella* hybrids acted like most naturally-occurring free-living N_2 fixers in fixing nitrogen only under anaerobic conditions and in the absence of combined nitrogen.

The ability of *Rhizobium* strains to fix nitrogen only when within nodules on the roots of legumes has puzzled scientists for more than half a century. These bacteria grow in culture media but have never been shown to fix nitrogen *in vitro*, a fact which has in the past often prompted the suggestion that the legume plant contributes at least part of the genes concerned with fixation. Dunican and Tierney suggest that the N_2-fixing ability is present though not phenotypically expressed in *R. trifolii* and this ability is expressed when transferred to a new bacterial host. The alternative explanation that genetic material transferred from the *Rhizobium* activates certain latent N_2-fixing genes in *K. aerogenes* cannot be entirely ruled out.

It is anticipated that this genetic system may be useful in studies of the physiology of legume root nodules and may also provide a means of improving strains of *Rhizobium* used in agriculture as seed inoculants. Legumes such as soybeans fix only about one quarter of their nitrogen requirements and a significant improvement in field fixation rates may be possible.

Radius of neutron distribution in lead

from Peter E. Hodgson
Nuclear Theory Correspondent

DURING the past few years there has been great interest in determining the sizes of atomic nuclei, and in particular the relative spatial extents of the constituent neutron and proton distributions. The proton distributions can be determined accurately from analyses of electron elastic scattering and muonic X rays, but the neutron distributions can only be determined indirectly, and the results are less accurate due to the lack of knowledge of the nucleon–nucleon interaction. Many different methods have been used, and the results are in substantial agreement.

On the whole it is found that the proton and neutron distributions are quite similar, with perhaps a slight tendency for the neutron distribution to extend further from the centre of the nucleus than the proton distribution, particularly for heavier nuclei. There is also the possibility of a 'neutron halo', a very diffuse neutron cloud extending far beyond the nuclear surface, where protons cannot reach due to the Coulomb field.

A quantity of particular interest is the ratio of the root mean square neutron and proton radii, as this is a convenient way of specifying the relative extents of the neutron and proton distributions. Recent work has tended to give a value of about 1.05 for this ratio though some studies have given values below unity.

A recent measurement of this quantity has used the (p,n) reaction to the isobaric analogue state of the target nucleus. This reaction concerns principally the outer neutrons and protons, and so is particularly sensitive to their densities in the surface of the nucleus. The final state has the same structure as the initial state and differs from it only by the substitution of a proton for a neutron in the highest quantum state. Another way of describing this is to say that the final state is formed from the initial state just by an isospin flip that changes a neutron into a proton. The interaction is thus brought about only by the isospin component of the nucleon–nucleon interaction, which determines the isospin term in the nucleon optical potential. Also affecting the isospin potential is the difference between the neutron and proton density distributions, so the reaction is sensitive to just the physical quantities of interest. All the interactions responsible for the (p,n) reaction are quite well known, and so is the proton distribution, so comparison between the experimental data and a series of neutron density distributions enables the latter to be determined.

The dependence of the cross section of these quantities is particularly simple if the distorted wave Born approximation is used. Then the cross section is proportional to the square of the transition amplitude

$$T(\mathrm{p,n}) = [2(N-Z)^{\frac{1}{2}} / A] \int \chi_n^-(r)\, U_i(r)\, \chi_p^+(r)\, d\mathbf{r}$$

where $\chi_n^-(r)$ and $\chi_p^+(r)$ are the waves describing the outgoing neutron and incoming proton respectively and the isospin potential

$$U_i(r) = [A/(N-Z)] \int u_t(|\mathbf{r}-\mathbf{r}'|) \{\rho_n(r') - \rho_p(r')\}\, d\mathbf{r}'$$

where $u_t(|\mathbf{r}-\mathbf{r}'|)$ is the isospin component of the nucleon–nucleon interaction and $\rho_n(r')$ and $\rho_p(r')$ are the neutron and proton density distributions respectively.

Schery, Lind and Zafiratos (*Phys. Rev.*, **C9**, 416; 1974) have measured the cross section for the (p,n) reaction to the isobaric analogue state of ^{208}Pb at 25.8 MeV. They calculated the cross section from the above formulae using standard values of $u_t(|\mathbf{r}-\mathbf{r}'|)$ and the optical potentials that fix the distorted waves $\chi_n^-(r)$ and $\chi_p^+(r)$. They assumed that the neutron density distribution has the form

$$\rho_n(r) = [1+\exp((r-R)/a)]^{-1}$$

and varied R and a to optimise the fit to the measured (p,n) cross section. The best fit accounted well for the angular variation of the crosssection, which confirms the reliability of the model. The optimum values of the parameters R and a correspond to a ratio of the root mean square radii $\langle r_n^2 \rangle^{1/2} / \langle r_p^2 \rangle^{1/2} = 1.07 \pm 0.03$, thus confirming previous work indicating a slightly larger neutron distribution. Since $\langle r_p^2 \rangle^{1/2}$ is 5.30 fm, the value of $\langle r_n^2 \rangle^{1/2}$ is 5.68 fm.

The stability of this result with respect to small changes in the assumed potentials was investigated, and this accounts for part of the suggested 3% uncertainty. Studies of the effect of the difference between the unbound proton wave function in the final state of ^{208}Bi compared with the corresponding bound neutron wave function in ^{208}Pb showed that the longer tail of the former reduces the ratio of root mean square radii by about 1%. The effects of two step contributions to the reaction was also studied and found to be small.

Plant messenger RNA and poly(A)

from our
Plant Cell Physiology Correspondent

THE discovery that many animal messenger RNA molecules contain regions of poly(adenylic) acid is of considerable interest (see *Nature*, **247**, 426 and 512; 1974). One reason for this is that the presence of poly(A) confers specific properties on mRNA molecules which can be exploited during RNA purification. Many workers have used columns of oligo(dT) cellulose or poly(U) sepharose which retain the mRNA by specifically base pairing with the poly(A) region. Another approach has been to use unmodified cellulose or nitrocellulose to purify the mRNA.

A recent report shows that presumptive mRNA from plants, long known for its high content of adenylic acid, contains poly(A) tracts (Higgins *et al.*, *Nature new Biol.*, **246**, 68; 1973). Sagher *et al.* (*Biochim. biophys. Acta*, **349**, 32; 1974) now suggest that the length of poly(A) in higher plants is of the order of 150–250 nucleotides which contrasts with the 50 or so residues found attached to yeast and fungal mRNA (McLaughlin *et al.*, *J. biol. Chem.*, **248**, 1466; 1973; Reed and Wintersberger, *FEBS Lett.*, **32**, 213; 1973; Silver and Horgen, *Nature*, **249**, 252; 1974). At present only the poly(A)-containing RNA from polyribosomes of plants which synthesise a large number of proteins has been analysed and not surprisingly it is heterodisperse. Individual mRNAs of known function have yet to be isolated but exploitation of the poly(A) tag may speed up the process. Although this approach to the study of mRNA metabolism holds out great promise it should not be accepted

without reservations. For example, it is by no means certain what proportion of mRNAs contain poly(A). In animals only the histone mRNAs have been shown to lack poly(A) but others may be added to this list and it is too early to assume that all plant mRNAs contain poly(A). It is also probably true that some nuclear RNA molecules that contain poly(A) do not function as mRNAs.

The most favourable situations for the isolation of a single mRNA exist where cells devote a large part of their protein synthesis to the production of one or a small number of specific proteins. One can anticipate that already in a number of laboratories there is a search under way for the mRNAs for the storage proteins of legume cotyledons and the larger and smaller subunits of the fraction I protein.

Nuclear magnetic order in solid ^{3}He

from a Correspondent

THE long predicted nuclear magnetic ordering transition in solid ^{3}He seems to have been observed at a temperature of 1.17 mK in an experiment carried out at Cornell University by Halperin, Archie, Rasmussen, Burhman and Richardson, and reported in a recent issue of *Physical Review Letters* (**32**, 927; 1974).

The compressional cooling technique used in this work, which has been developed during the past few years by the low temperature group at Cornell, has already been extraordinarily fruitful in that it has led to discovery of the two new and apparently superfluid states of liquid ^{3}He. The technique, known as Pomeranchuk cooling after the Russian physicist who originally suggested it, is based on the fact that for temperatures below about 0.3 K, ^{3}He has a negative latent heat of solidification so that, unlike other materials, it absorbs heat while changing phase from liquid to solid.

In practice, after being precooled to about 15 mK by means of a dilution refrigerator, the liquid is then steadily compressed by the application of external pressure. At a pressure of about 34 atmospheres it starts to solidify and, because heat is thus being absorbed, it also starts to cool. The cooling effect can be maintained until, eventually, the cell is entirely filled with solid. The final temperature depends on a number of factors including the starting temperature, the rate at which heat leaks into the system or is developed by mechanical inefficiencies in the compression mechanism itself, and the rate at which the liquid is compressed, but is usually in the range 1–2 mK. The ^{3}He, which is the subject of the present experiments, is thus able to act as its own refrigerant from which accrues the enormous benefit that the usual formidable problems of thermal transfer and equilibrium in the low mK temperature range are automatically minimised.

Unlike ^{4}He, the ^{3}He nucleus possesses a magnetic dipole moment and it is to be expected that, at some sufficiently low temperature T_c, a transition will occur in which the nuclei become aligned in some ordered fashion relative to each other. Because the nuclear moments are so tiny the ordering temperature is bound to be exceedingly small and, just considering the direct magnetic interaction of the nuclei, it may be calculated that $T_c \sim 10^{-6}$ K. More refined calculations, however, taking account of the so-called exchange forces, suggest $T_c \sim 10^{-3}$ K, which is just within the experimental range made accessible by Pomeranchuk cooling.

In essence the basic Cornell experiment was extremely simple: the volume occupied by the ^{3}He was reduced at a steady rate while its pressure was continuously monitored. The pressure, with a mixture of liquid and solid in the cell, was necessarily always that of the melting curve at the relevant temperature and, since the melting pressure increases with falling temperature, the pressure automatically gave a measure of the temperature. Under these conditions a plot of pressure P against t is almost linear, corresponding to cooling of the sample at a constant rate, provided that no phase changes occurred in either liquid or solid apart, of course, from the continuous solidification-action process responsible for the refrigeration. In practice, the original experiment showed one change of slope and one discontinuity in the $P(t)$ plot, and these were eventually proved to be caused by two superfluid transitions in the liquid phase. In the present work a third anomaly in the $P(t)$ graph was observed at the even lower temperature of 1.17 mK.

The interpretation of these experiments, where both liquid and solid are simultaneously present, is of course extremely difficult. Through a series of ingenious additional experiments, however, in which heat pulses were applied to the helium while compression was continued at a steady rate, the authors seem to have demonstrated unambiguously that the $P(t)$ anomaly at 1.17 mK corresponds to a phase change within the solid, which must presumably represent the onset of magnetic ordering, and they have been able to deduce that the entropy of the solid falls by a factor of 5 within a temperature range of only 100 μK.

It has not been possible from these experiments to deduce the nature of the magnetic order below T_c. Measurements of the nuclear susceptibility at higher temperatures had led to the development of a detailed model which predicted a transition at 2.2 mK to an antiferromagnetic state, in which neighbouring nuclei point in opposite directions. The fact that the actual transition has now been found to occur at only half this temperature is in itself strong evidence of the inadequacy of this model. A great deal of further work will certainly be required before a proper understanding of magnetic ordering in solid ^{3}He can be attained, but it is very encouraging to know that the phenomenon occurs in a temperature range which has now become accessible to experiment.

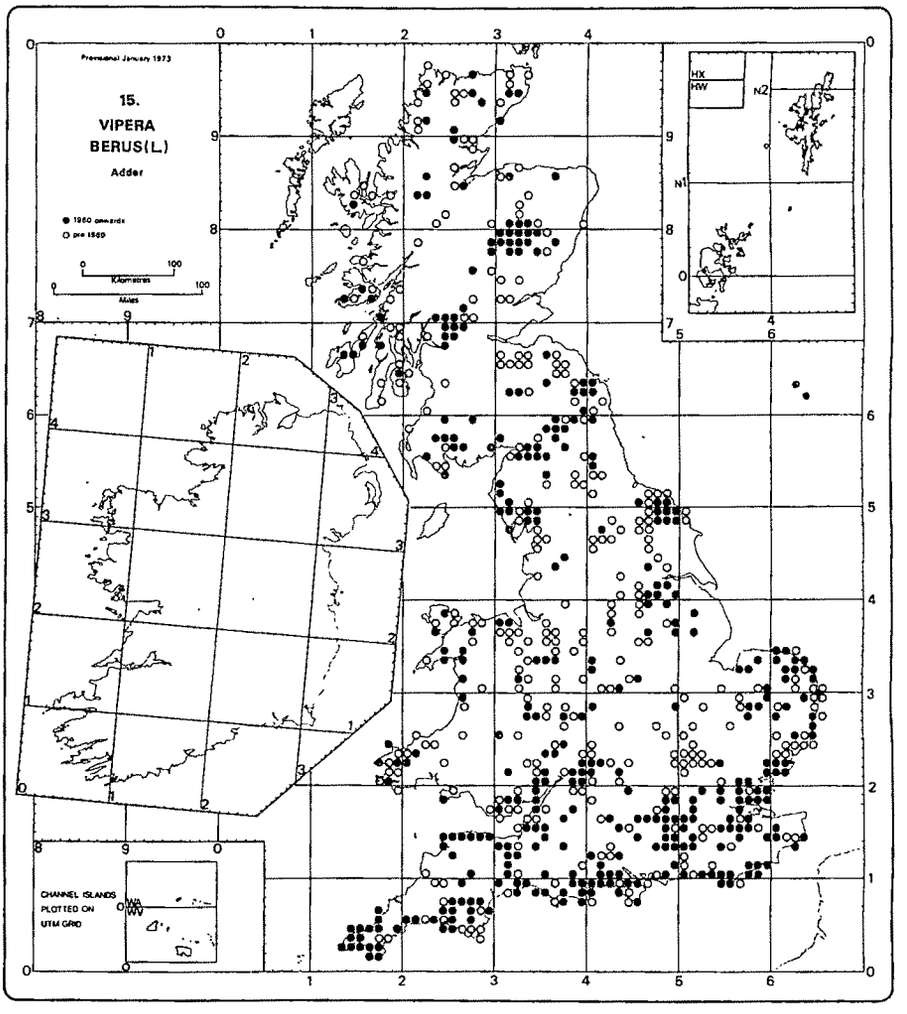
Chemical heat at oceanic ridges

from Peter J. Smith
Geomagnetism Correspondent

NEAR the crests of active oceanic ridges the mean heat flow is generally higher than the global average, and measurements are considerably more scattered than those in, for example, typical ocean basins. Both of these observations are explicable in general terms, for hotter mantle-derived material rises beneath ridge crests to form new ocean floor, and a combination of rugged ridge topography and uneven sediment cover tends to produce both high measurement errors and a distortion of the heat flow pattern (for example, by thermal refraction). Nevertheless, in view of the importance of testing the seafloor spreading hypothesis as rigorously as possible, such loose explanations are not entirely satisfactory; and it is not unreasonable to suspect that the rather messy heat flow picture may be concealing important information about physical and chemical processes in mid-ocean regions.

Because of the large scatter of data, for example, there may be legitimate doubt about the validity of the mean heat flow values themselves, all the more so as McKenzie (*J. geophys. Res.*, **72**, 6261; 1967) has shown that they are inconsistent with the formation of new oceanic crust at a reasonable temperature. Mean heat flow as measured over ridge crests may indeed be high, but it is not as high as might be reasonably expected.

Recognising the scope for investigation here, Lister (*Geophys. J.*, **26**, 515; 1972) made an important series of heat flow measurements on the Juan de Fuca ridge and near the Explorer trough in which he took care to assess topographic effects and the thermal influence of recent sediment disturbances. The conclusion he came to was that the thermal balance of a ridge crest zone can be interpreted in terms of a



simple model of seafloor spreading, but only if a considerable part of the surface heat loss at the crest is non-conductive. He thus proposed that in addition to conduction, a significant proportion of crestal heat is carried away by convection in the form of open hydrothermal circulation within the upper 5–10 km of the rock material at the ridge crest. The critical requirement here is that the oceanic crustal rocks should be permeable enough for the circulation to take place; and although relevant data are sparse, there seems little doubt that this is the case. Accepting hydrothermal flow, therefore, it follows that the (conducted) heat measured will be less than the total heat actually generated, thus explaining the discrepancy noted by McKenzie.

The existance of hydrothermal circulation may also explain other things, including the long-time puzzle of why anomalously low heat flow is commonly found on ridge flanks. Moreover, in a rather different field, and as Spooner and Fyfe (*Contr. Mineral. Petrol.*, **42**, 287; 1973) have discussed at some length, "vigorous convective circulation of brine within the oceanic crust" seems to be the phenomenon most likely to account for the pattern of metamorphic rocks found on the ocean floors. In other words, hydrothermal flow is "a significant process at axes of seafloor spreading". Just how significant it is in thermal terms is indicated by a simple calculation. One cubic kilometre of liquid basalt at 1,200° C could heat 3 km^3 of sea water to 300° C (lower than the boiling point at a depth of 1 km under a hydrostatic pressure gradient). This means that at the present rate of magma production all oceanic water could be so heated during circulation through oceanic crust in about 100 million years. As Spooner and Fyfe pointed out, all this suggests that convection within the crust constitutes the major process by which the cooling of the intrusive material in the crust takes place.

But Fyfe (*Geophys. J.*, **37**, 213; 1974) has now drawn attention to another implication of hydrothermal flow. The chemical processes induced by such circulation are oxidation, hydration, carbonation and the fixation of sulphur, all of which are exothermic reactions. Thus magmatic heat induces large-scale convection and the convection then induces further heat-producing reactions. To estimate just how much heat is likely to be generated in this way, Fyfe assumes that the upper 15 km of the oceanic crust cal and hydration of basaltic pyroxene (a thicker section than Lister suggested, to "allow for some tectonic mixing of the surface layers as the conveyor belt moves") and that the crust comprises 10 km of basalt and 5 km of peridotite. He then calculates that, in a 1 cm^2 column, serpentinisation of the peridotite would produce 10^8 cal, oxidation of 10% FeO in basalt would give 2×10^8 cal, hydration and addition of CO_2 to basaltic anorthite would yield 2×10^8 cal and hydration of basaltic pyroxene would give 10^8 cal. This gives a total heat source of about 6×10^8 cal —comparable to the radioactive heat generated in an equivalent column of granite over a period of 20 Myr.

Insofar as the chemical reactions considered by Fyfe are probably simpler than those actually taking place, the accuracy of this estimate of heat production is difficult to assess. Nevertheless, it is obvious that there is a potential heat source here which is far from trivial. Fyfe contends, therefore, that such chemically generated heat can hardly be ignored in considering the thermal regime of the ocean floor and oceanic ridges.

Atlas of British amphibians and reptiles

THE number of adders (*Vipera berus*) present in the British Isles seems to be reasonably healthy; as this distribution map shows, records of sitings have been returned from most parts—except, of course, from Ireland. As the new *Provisional Atlas of the Amphibians and Reptiles of the British Isles* (edit. by Arnold, Biological Record Centre, 25p) reports, however, three of the remaining 11 indigenous species—the natterjack toad (*Bufo calamita*), sand lizard (*Lacerta agilis*) and smooth snake (*Coronella austriaca*)—are now extremely uncommon and will need protection if they are going to survive. Staff at the Biological Records Centre at Monks Wood Experimental Station, Abbots Ripton, are aware of the provisional nature of the atlas; there are several areas where no recording of the commoner species has been done and they will be pleased to receive any record that fills in a gap on one of the maps. The atlas includes brief notes on the identification of species.

Solar geomagnetic disturbances and weather

by John Gribbin

ONE of the key links in the developing theory that atmospheric circulation (and hence climate) on Earth is affected by solar activity has been provided by evidence that geomagnetic activity can be connected with a deepening of troughs in the atmosphere. But although evidence presented by Roberts and colleagues (see *J. atmos. Sci.*, **30**, 135–140; 1973) has seemed to show that troughs at the 300 mbar level level are affected in this way, and although other groups have presented evidence that even surface pressure responds to solar geomagnetic disturbances (see Mustel, *Soviet astr.*, **10**, 288–294; 1966) the reality of the claimed effect has been queried by others. In particular, Stolov and Shapiro found no evidence to support the claim that atmospheric circulation is disrupted during disturbed geomagnetic periods, according to a paper published three years ago (*Proc. Symposium on Solar Corpuscular Effects in the Troposphere and Stratosphere*, Moscow, 1971). So the recent publication of another paper by the same two authors, in which they report that a reanalysis of the data does show such an effect, is particularly important (*J. geophys. Res.*, **79**, 2161–2170; 1974).

The reason for the emergence of the effect from the new analysis seems to be that the strong seasonal trend in 700 mbar heights which is introduced by ordinary meteorological factors must be removed before the solar geomagnetic effect can be picked out from the data. The data themselves are comprehensive, covering the period January 1, 1947 to December 31, 1970. They consist of sea level pressures and 700 mbar heights measured at 5° latitude intervals and 10° longitude intervals in a diamond shaped grid over 20° to 70° N. The solar geomagnetic incidents studied in the analysis were chosen from a variety of sources which gave a total of 454 events, some of which were related to one another.

Using a superposed epoch analysis and removing the seasonal effects which dominate the atmospheric variations, Stolov and Shapiro find "firm statistical evidence . . . that strongly suggests the existence of a real relationship between solar geomagnetic storms and the subsequent behaviour of the 700 mbar contour height". The effect is more pronounced in winter, when the zonal flow is increased 4 days following geomagnetic disturbance. In summer, a smaller but still significant effect occurs 2 days after such disturbances. At its maximum (for the quadrant 90° to 175° W in winter) the effect corresponds to a 7% increase in the mean westerly flow. Stolov and Shapiro say that "no acceptable physical observations are available to explain the observations"; however, that no longer seems to be strictly true in the light of King's recent investigation of links between the magnetosphere and atmosphere (*Nature*, **247**, 131–134; 1974). What is certainly true is that further statistical studies are needed, and that these might contribute both to weather forecasting and to an understanding of climatic change.

Vole populations and their diet

from our Animal Ecology Correspondent

ONE of the greatest drawbacks to the theories which purport to explain the factors causing vole population cycles is their relative untestability (for example, Chitty, *Can. J. Zool.*, **38**, 99; 1960; Christian and Davis, *J. Mammal.*, **47**, 1; 1966) and recent attempts to elucidate behavioural or genetic factors have been inconclusive. Batzli and Pitelka (*Ecology*, **51**, 1027; 1970) and Schultz (*Symp. Brit. Ecol. Soc.*, 57; 1964) have suggested that nutritional aspects of forage may play an important part in regulating cycles. These could take the form of potassium or phosphorous deficiencies which bring about specific or general debility.

Another nutritional factor which might be involved is the toxicity of many food species of plant (Freeland, *Am. Nat.*, **108**, 238; 1974). From the huge mass of published work on species preferences of vole food at various stages of the population cycle, Freeland argues that the loss of animals from peak population densities is the direct result of reduced viability induced by the consumption of plants, or parts of plants, that contain toxins. It is known that quite small amounts of toxins imbibed by voles cause inhibition of protein synthesis and growth, cessation of the reproductive processes, occurrence of megalocytes in the liver together with haemorrhagic necrosis, hypertrophy of the spleen, and cause neural and digestive disorders. If a vole eats more than one toxic species the effect of the toxins they contain may be mutually enhanced.

Freeland puts forward a hypothesis with four central tenets: (1) voles must have a preference for non-toxic species; (2) with increasing population numbers these preferred foods should become scarcer with a concurrent increase in availability of non-preferred, toxic species; (3) at high population densities voles ingest quite large quantities of toxic foods leading to a reduction in growth and a slowing of reproduction; and (4) in the absence of grazing, the preferred non-toxic species should compete more strongly for space than the less preferred toxic species. The replenishment of favoured food so produced following a 'crash' of population allows another cycle to start.

In 1965 Thompson (*Amer. Midl. Natur.*, **74**, 75) examined the toxicity level of many food species of the voles *Microtus pennsylvanicus* and *M. californicus* in relation to their preferences of selection. A plant was ranked as toxic only if it was known to contain a compound or compounds that cause death or severe physiological damage. Bitter tasting or foul smelling species were not rated as toxic unless a truly toxic compound occurred as well. The result of Thompson's laboratory trials was that voles prefer non-toxic plants like *Trifolium repens* and *Lolium multiflora* to toxic ones like *Ranunculus* and *Rumex*. Batzli and Pitelka have found that during one cycle of *Microtus* abundance the amount of toxic species available becomes relatively more abundant in the face of a diminishing supply of preferred species. The establishment of exclosures indicated that non-toxic species out-compete toxic ones. In areas grazed by voles there is a reciprocal fluctuation of the relative abundances of these two species types.

Krebs *et al.* (*Ecology*, **50**, 587; 1969) have noted that during population decline the rates of disappearance of different age and sex classes of voles are not the same. There is evidence that male sex hormone increases the activity of liver microsomal enzymes which bring about the degradation of toxins (Parke, *The Biochemistry of Foreign Compounds*, Pergamon, Oxford; 1968). So the differential mortality rates frequently observed by field workers is a phenomenon not incompatible with Freeland's hypothesis.

The crux of the hypothesis is that numerical change must come about sufficiently slowly for there to be a compositional change in the vegetation. Even though *Microtus* and similar rodent species have a high capacity for population increase, natural wastage to predation keeps the numbers low enough to avoid a hasty overgrazing of the vegetation. The slow build-up of rodent numbers produces a slow increase in availability of toxic species which, in time, decreases rodent abundance and allows the whole cycle to start again.

This hypothesis has merit and warrants close scrutiny. At the same time could population ecologists consider not so much how the cycle works as much as why it happens at all? Are cyclical rodents really in such a bad state of balance with their ecosystems, or is there another reason?

How history has blended

H. V. Wyatt

Department of Biology, University of Bradford, Bradford BD7 1DP, UK

The experiments of Hershey and Chase, giving evidence that DNA is the genetic material, have been greatly simplified and modified in subsequent descriptions. Students are in danger of receiving a quite misleading impression of the process of scientific discovery.

IT was the classic paper of Hershey and Chase[1] which marked the psychological watershed after which DNA was rapidly accepted as the genetic material of living organisms. Looking back, it is difficult to see why this work was accepted whereas Avery's demonstration that transformation was effected by DNA took longer to be appreciated (see for example refs 2–5). Moreover, whereas Avery's 1944 paper[6] still holds, the conclusions of Hershey and Chase have since been modified in detail.

The tightly constructed and interlocking experiments of Hershey and Chase have in most cases been reduced to only one experiment—the Blender experiment—which can be vividly portrayed by diagrams and is therefore popular in the textbooks. In the process of canonisation, their experiments are remembered 'with advantages'.

In this account, I attempt to review the Hershey and Chase experiments in the context of the discovery of transformation and the identification of the genetic role of DNA and to show how they have since been admitted to the Pantheon.

In their paper[1], Hershey and Chase describe the experiments in the following order. (1) Plasmolysis produces phage ghosts of protein and releases DNA into solution. (2) Phage DNA becomes sensitive to DNase after adsorption to heat-killed bacteria. (3) Phage DNA is liberated when phage adsorbs to bacterial fragments. (4) Removal of phage coats from infected bacteria (the Blender experiment). (5) Only 1% of the sulphur from the infecting phage is transferred to the progeny (including a modified Blender experiment). (6) Thirty per cent of the phosphorus from infecting phage is transferred to the progeny. (7) Formalin-inactivated phage can attach to, but cannot inject their DNA into bacteria.

The experiments formed a logical sequence. The first three provided further evidence for the functional differentiation of the protein coat from the enclosed DNA and continued the work of Herriott[7] and Northrop[8]. The Blender experiment (a term used by Hershey[9]) showed this elegantly. Experiments 5 and 6 were altogether different and showed differential transfer of protein and DNA to phage progeny. The most important experiments, 4 and 5–6 are therefore complementary: alone, none is convincing. The two sets of experiments originated from two sources[2,9]. The Blender experiment followed from Herriott's idea[7] of a microsyringe the genesis of which lay in Avery's work and that of Hotchkiss. The progeny experiments followed those of Watson and Maaløe[10].

The Blender experiment has since achieved so much fame that it is almost the only part of the Hershey and Chase paper which is still quoted. The novel use of the Waring Blender has perhaps stirred the imagination. Davis *et al.*[11] for instance give an account of experiment 2 and of the Blender experiment, adding that these showed that "the phage DNA carries the genetic information and that infection consists of the penetration of the viral DNA into the cells". The results of the Blender experiment varied throughout the paper (Table 1), doubtless because a number of different experiments were reported in different contexts. The experiments showed that 65 to 85% of the ^{32}P and 25 to 18% of the ^{35}S was not stripped from the bacteria. Hershey and Chase inferred from both types of experiment only that the protein coat "probably has no function in the growth of intracellular phage. The DNA has some function." They added "Further chemical inferences should not be drawn." In the discussion they stated that the following questions remain unanswered. (1) Does any sulphur-free phage material other than DNA enter the cell? (2) If so, is it transferred to the phage progeny? (3) Is the transfer of P to progeny direct or indirect?" At the Cold Spring Symposium, Hershey[9] spelt out the limitations of the Blender experiment. (1) Does the 20% of the virus DNA which is strippable mean that some of the DNA of the virus is dispensable or that some fails to inject? (2) Does the 20% of the protein that is not strippable have any function in the growth of the intracellular virus? (3) Does the non-strippable protein consist of the stubs of the tails only, or is some protein injected along with the DNA?

Acceptance of the Blender experiment

Mirsky suggested[12] that the purity of DNA—the transforming principle—might include 2 to 3% protein even in a so-called pure preparation. It was this degree of contamination which made it seem possible that protein might still be the genetic carrier because Mirsky calculated that transformation required about 10^9 molecules of transforming principle.

Hotchkiss had meanwhile shown that the amino acid recovered from acid hydrolysates of purified transforming principle was glycine, arising from hydrolysed adenine—not from contaminating protein. This work was originally published in France[13] and virtually lost[14]. Hotchkiss, however, later gave it at a symposium attended mainly by biochemists and probably only Herriott from the phage groups[2]; the contamination of transforming DNA by protein was less than 0.02%, if at all[15].

Yet the contamination in the Blender experiment was of the order of 25%; why was this ignored by those who accepted the phage work? First, in the Blender experiment, almost all the infected bacteria survived the treatment and produced infectious phage and almost all had been infected by only one phage (ratio of phage to bacteria was 0.28). The contamination of protein (^{35}S) in the Blender experiment was shown in a non-blender experiment to be associated with the bacterial cell wall and to be mainly coats of patental phage particles, presumably identical with the coats which could be sheared off. Hershey and Chase concluded that this protein probably never entered

the infected cell. In the next experiments they found that < 1% of the ^{35}S could be recovered from progeny phage: this moreover was divided among an average of > 30 phage progeny per parent phage. This would not be very convincing if replication was of a non-conservative type but thinking about replication was necessarily vague at this time.

This might have implied that less than 0.03% of the phage protein was necessary for the transfer of genetic information. The most difficult objection would have been if the genetic material had been protein and that this protein had contained little or no sulphur-containing amino-acids. An experimental technique similar to that used by Meselson and Stahl[16] might have resolved this difficulty. The experiment of Meselson and Stahl is itself a blend of Avery's isolation of DNA and of Hershey and Chase's use of isotopic recognition.

How Hershey and Chase have been quoted

The paper has been reprinted in full in reprint collections[17,18] and, with the omission of pages 39–44 and Tables 1–3 in other collections[19,20]. It is therefore widely available. Most authors quote only the Blender experiment with its results as shown in Table 2. Hayes[21], Stent[22,23] and Davis *et al.*[11] give details of other experiments in the Hershey and Chase paper. Some authors give accounts of subsequent experiments. Herskowitz[24] gives not the results of the experiment he describes but an idealised interpretation and attributes the account in a footnote "this account follows the work of A. D. Hershey and M. Chase". Diagrams of the experiment are given by Clowes[25] and by Fraser[26]: a diagram in Levy *et al.*[27] is however confusing as it seems that the same phage is labelled with both ^{32}P and ^{35}S although the text is clear. Ravin[28] is also confusing, saying that Hershey and Chase "... grew the viruses on bacterial hosts in a medium containing sulphur (^{35}S) and phosphorus (^{32}P)". A flow diagram of the experiment in Kreuger *et al.*[29] not only obscures the elegance of the original but confuses the reader.

The only reproduction of the figure from the original[1] paper is in Stent[23]—although a figure showing "representative results of the Hershey–Chase 'blender' experiment" is given in Kreuger *et al.*[29]. Stent[22] says that the "Blender experiment ... consists of infecting bacteria with ^{32}P, ^{35}S or ^{14}C labelled phage particles" and details the results as "more than 80% of the viral sulphur and amino-acid carbon ... more than 80% of the viral phosphorus or purine-pyrimidine carbon". The isotope ^{14}C was used by Watson and Maaløe[10] to label purines in their experiments when they found equal transfer of phosphorus and purines to phage progeny. In the conversations recorded from a conference, Stent[5] quotes the results of the Blender experiment as "the Hershey–Chase experiment", saying that the experiment was rather weak. This is probably true of that experiment in isolation but it was surely the combination of experiments that made the paper[1] so convincing.

Pollack[30] stated that "with Hershey and Chase's demonstration that bacteriophage left all (that is, experimentally more than 99%) of their protein coat and other superficial 'apparatus' behind on infection of the cell, it became very difficult still to maintain that nucleic acid was not the key substance in the maintenance of genetic continuity". This is a blending of the Blender experiment with the results of the transfer of parental phage radioactive sulphur to progeny phage (1%). Although this is the furthest from accuracy, it nevertheless conveys the general impression of the entire paper more cogently than the quotations of the Blender experiment alone.

A comparison of the figures in Tables 1 and 2 shows that only Stent[23] could have taken his figures from the original (text on page 48). A number of the figures are outside the limits of the results given in the paper from which they are supposed to be taken. The figures of 20% ^{32}P and 80% ^{35}S eluted are the most common and are given by Hershey in his summary of the work[9]. It is difficult to believe that so many authors have consulted this paper and not the original. It is more probable that these figures, now part of the myth, stem from an original quotation, now forgotten.

Effects of idealising experiments

Original experiments are not quoted in textbooks to give authority to the statements and general principles or facts which follow. Rather they are quoted to give a sense of historical perspective to the matter and to relate it to other material. Quoting a name provides a handy label for recall of the matter and perhaps unconsciously a handle for examination questions. Authors may also feel they are sugaring the pill with human interest. Where an experiment is quoted in detail, it is surely to show an example of an elegant economical experiment—a model to strive towards. It should illustrate the clarity of the experimenter's aims and of his reasoning and it should show how far the results meet those required for a definitive answer; it usually shows how a single experiment or a single experiment as the culmination of others, can set scientists on a new path. The very existence of books of selected reprints and their use for teaching[19] shows how important these experiments are considered.

It is therefore of concern that so many textbooks are guilty of trivialising the experiments of Hershey and Chase. By reducing the complementary experiments to only the Blender experiment these textbooks diminish the elegance of the work and destroy the intricacy of the interlocking evidence: each step is in itself inconclusive, but *in toto* they are overwhelmingly convincing. If students accept these textbook accounts they are being taught not science but magic, which can be seen even more clearly in many practical textbooks. A favourite experiment, shown, for example, on a film currently in academic use, consists of precipitating a polymer (presumed to be DNA) and showing that addition of this substance to bacteria increases the number of mutants which can be isolated by selection. It is alleged that this experiment shows that DNA is the specific chemical substance which carries genetic information. As Avery *et al.*[6] showed, the scientific demonstration that DNA is the carrier of genetic information is difficult and laborious (ref. 3 and my unpublished work). We are educating a generation of scientists who may well believe that crucial experiments need no controls and give only rather vague results.

The other aspect of the quotations in Table 2 is evidence of the rapid conversion of scientists to a new dogma. The original evidence is soon forgotten and a gradual process of improvement ensues. The cracks in the edifice are easily overlooked because they are not present in the idealised model. This faith may be necessary so that the majority of scientists can proceed unworried with their work. But it is the young

scientists who can see the cracks and do the next elegant, economical experiment who will found the new dogma.

Nitrogenase

Robert R. Eady & John R. Postgate

ARC Unit of Nitrogen Fixation, University of Sussex, Brighton BN1 9QJ, Sussex, UK

The protein components of the enzyme system nitrogenase, responsible for the fixation of nitrogen by microbes, have been purified and characterised from several sources. Examination by physicochemical and kinetic methods is revealing an elaborate reaction mechanism involving electron transport from one protein to the other promoted by reaction with Mg–ATP.

NITROGENASE is the name given to the enzyme system responsible for biological nitrogen fixation, the reduction of dinitrogen (N_2) to ammonia[1]. In the past three years, techniques for handling these O_2-sensitive proteins have improved and sufficient highly purified material has become available for mechanistic studies at the enzyme level. Mössbauer spectroscopy, electron paramagnetic resonance (EPR), rapid reaction kinetics and classical steady state kinetics are converging to advance understanding of the mode of action of the enzyme. The basic action pattern seems to be similar whether the enzyme system is obtained from the strict anaerobe *Clostridium pasteurianum*, the facultative anaerobe *Klebsiella pneumoniae* or the aerobe *Azotobacter vinelandii*. Here we survey the state of the enzymology of nitrogenase at the end of 1973; recent reviews of nitrogen fixation are given in refs 2–5.

Nitrogenase system

Nitrogenase consists of two proteins, one containing molybdenum, iron and acid-labile sulphur (Mo–Fe protein) and the other iron and labile sulphur (Fe protein). Both are essential for activity, together with Mg^{2+} and ATP. ADP is a reaction product; it can inhibit nitrogenase and experimental stratagems are necessary to avoid its accumulation (see ref. 2). High Mg^{2+} concentrations can inhibit, probably by sequestration of ATP as an inactive Mg–ATP complex[6].

In addition to N_2, which is reduced without formation of detectable intermediates, nitrogenase reduces a variety of triply-bonded nitrogen analogues (C_2H_2,HCN,N_2O,$CH_3N{\equiv}C$). If no reducible substrate is supplied, hydrogen ions are discharged as H_2; this reaction is not completely suppressed by other substrates *in vitro*. Carbon monoxide inhibits all but the hydrogen-evolving function of nitrogenase[2–5]. The reduction of C_2H_2 has been adopted as the now famous 'acetylene test' for nitrogen fixation[7]; the reduction products of the other analogues suggest that substrates bind to a transition metal during enzyme function[2,5].

Nitrogenase preparations from a number of organisms have been fractionated into two components both of which are required for activity (Table 1). The Mo–Fe proteins from *C. pasteurianum*[8–10], *K. pneumoniae*[11], *A. vinelandii*[12,13], the bacteroid form of *R. japonicum*[14] from soya bean nodules and the Fe proteins of *C. pasteurianum*[10,15] and *K.pneumoniae*[11] have been highly purified.

Nitrogenase components from one organism will often cross react with components from other organisms to give functional enzymes. Table 2 summarises the position at the end of 1973; many of the tests did not use purified nitrogenase components so the table is expressed in only semi-quantitative form.

Both proteins are irreversibly inactivated by oxygen. The Fe protein is particularly sensitive, therefore purification under an oxygen-free atmosphere is mandatory, and usually $Na_2S_2O_4$ is included as an O_2 scavenger in buffer solutions used during purification. Otherwise purification schemes make use of familiar techniques of protein chemistry[5].

The extreme O_2 sensitivity of nitrogenase poses a special problem for aerobic N_2-fixing organisms, particularly those which are aerobic and/or photosynthetic. Some strains of blue-green algae protect their nitrogenase from oxygen produced during photosynthesis by compartmentation of the enzyme into specialised thick-walled cells termed heterocysts, which lack photosystem II, the O_2-producing photosynthetic system. Species of N_2-fixing algae exist which do not form heterocysts, but they generally fix N_2 only at low pO_2 values or low illumination levels[16]. Azotobacters have an elaborate physiological protection mechanism for their nitrogenase which has been reviewed recently[17].

They have a very high respiratory rate which is closely coupled to prevailing O_2 tension in the culture and which provides a dynamic process for lowering the dissolved oxygen concentration to a level at which nitrogenase can function. Extensive O_2 stress probably causes a 'conformational protection' of O_2-sensitive nitrogenase which gives rise to an inactive but O_2-tolerant form in the intact organism. Such an O_2-tolerant particulate form of nitrogenase is present in crude extracts of *A. vinelandii* and *A. chroococcum*, in which the enzyme proteins are stable in air and become O_2-sensitive only during purification or on the addition of ATP or other nucleoside triphosphates[18]. A soluble O_2-sensitive nitrogenase can be isolated from azotobacters by osmotic shock[19]; O_2-sensitively of nitrogenase components is apparently influenced by association with membranes, NADH oxidase[20] or ATP.

Ammonia, the product of enzymic nitrogen fixation, does not inhibit nitrogenase activity, but represses synthesis of the nitrogenase system. In *K. pneumoniae* this control occurs at the transcriptional level[21]. Other sources of fixed nitrogen such as NO_3^- or urea also inhibit synthesis of nitrogenase if they penetrate the cell. Studies on the regulation of nitrogenase in *A. vinelandii*[22] suggest coordinate control of the level of both nitrogenase components. During repression, activity of the Mo–Fe protein decreases rapidly and at the same rate as its characteristic EPR signal at g=3.7 (below), but immunologically active material persists for much longer.

Nitrogenase proteins

The Mo–Fe proteins. Homogeneous preparations of this protein have been obtained from *C. pasteurianum*, *K. pneumoniae*, soya bean bacteroids, *Chromatium vinosum* and *A. vinelandii*; data are collected in Table 3. It is usually a heteromeric tetramer in free-living bacteria but is homomeric in bacteroids. The protein from *A. vinelandii* has been crystallised[12] but the crystals are too small for X-ray analysis. Crystallisation is an unreliable criterion of purity[13].

The Fe content ranges from 18–34 Fe atoms per mol, and is approximately equivalent to the acid-labile sulphide content. Reported Mo range from 1–2 atoms per mol. A preparation from *C. pasteurianum* containing 1 Mo atom per mol was separated into a protein with increased activity containing 2 Mo atoms per mol[23], and an inactive species with 0.5 Mo atoms per mol[24]; the two species were nearly identical in amino acid composition, subunit structure and in immunological reaction. Zumft and Mortenson[24] suggested that other seemingly homogeneous preparations might consist of a mixture of dimolybdo and demolybdoproteins. Nothing is known about the distribution of metals within

the subunits since (i) the metals do not exchange with isotopes and (ii) the treatment with acid or detergent required to dissociate the subunits releases both metals[23].

All common amino acids are present, (see Table 4) with a high proportion (about 20%) of aspartate and glutamate, which are about twice as abundant as arginine and lysine. The protein from *C. pasteurianum* has a very much lower content of tryptophan than the other proteins and has two C termini, consistent with two different polypeptide subunits. When the compositions are used to estimate compositional relatedness[25], and to predict the probable degree of sequence homology[26], the proteins from *A. vinelandii* *K. pneumoniae* and soya bean bacteroids prove to be more closely related to each other than to that from *C. pasteurianum*. It would be premature to speculate how conservatively the amino acid sequence has been preserved within this group of proteins but the inability of the protein from *C. pasteurianum* to produce an active nitrogenase with complementary proteins from the other organisms (Table 2) might well reflect these differences.

Mo–Fe proteins from *C. pasteurianum*[27,28], *K. pneumoniae*[29,30], *Chromatium vinosum*[31] and *A. vinelandii*[12,28] have a unique and characteristic EPR spectrum below 30 K with g=2.01, 3.7 and 4.3 (Table 3). These resonances are most intense in the presence of $Na_2S_2O_4$, and diappear on oxidation with a dye and also in the functioning nitrogen-fixing system. Palmer *et al.*[27] suggest that they originate from an antiferromagnetically coupled system of iron atoms with an effective spin state of S=3/2. Molybdenum is, in principle, more likely than Fe to produce this species, but enrichment with ^{95}Mo (nuclear spin 5/2) produced no hyperfine structure[27,30,31] whereas enrichment with ^{57}Fe (nuclear spin 1/2) produced some line broadening[30]. Hence Fe atoms are the probable source of the resonances. The precise g values and line widths of the protein of *K. pneumoniae* are *p*H dependent, and the substrate analogue C_2H_2 displaces the signal in favour of the high *p*H form[30].

The Mo–Fe protein of *K. pneumoniae* labelled with ^{57}Fe has been investigated by Mössbauer spectroscopy[32] and three redox states of the undamaged protein can be detected. In the presence of $Na_2S_2O_4$, as normally isolated, the spectrum at 195 or 77 K consists of three overlapping quadrupole pairs of absorptions with relative intensities corresponding to iron sulphur clusters containing 2, 8 and 8 iron atoms. One of the groups of 8 atoms has magnetic properties and has been correlated with the EPR active species. In functioning nitrogenase a more highly reduced form of the Mo–Fe protein appears. Oxidation of the protein gives Mössbauer spectra different from any others, particularly from those observed during catalytic activity; a species formed by oxidation with Lauth's Violet retains full enzyme activity. Extensive O_2 damage results in spectra characteristic of ferric oxide or oxyhydroxide and presumably reflects destruction of the chromophore. A Mössbauer spectrum of the protein from *A. vinelandii*[33] has parameters similar to those of the oxidised protein from *K. pneumoniae*, with possible contributions from O_2-inactivated protein.

The ultraviolet and visible spectra of the Mo–Fe proteins from all sources[9,11–13,31] are characteristic of iron–sulphur proteins with more than two Fe and S^{2-} atoms per molecule. Their solutions are brown and have an absorption maximum near 280 nm. There are no maxima in the visible region, but rather a broad absorption extending from about 350 nm to well into the near infrared. The circular dichroism spectra of the proteins from *K. pneumoniae*[11] and *C. pasteurianum*[34] are very similar, consisting of negative troughs near 210 nm and 220 nm associated with α-helical structure. They are exceptional among iron–sulphur proteins in that they do not show the optical activity in the visible region found with ferredoxins and xanthine oxidase[35].

Redox titrations of the proteins from *K. pneumoniae*[36], and *C. vinosum*[37] indicate a difference of two electrons per mol between the dye-oxidised and $Na_2S_2O_4$-reduced forms but a value of four electrons per mol has been reported for *C. pasteurianum*[38]. The protein of *C. vinosum* has two centres with identical EPR spectra which undergo single electron reductions with midpoint potentials of −60 mV and −260 mV; this differs from *C. pasteurianum* where a four electron reduction at −70 mV is thought to occur[38].

The Fe protein. Only the proteins from *C. pasteurianum*[10,15] and *K. pneumoniae*[11] have been obtained in homogeneous form; their properties are shown in Table 3. The extreme O_2-sensitivity of these proteins is a major obstacle in purification. The proteins from *A. vinelandii* and *C. pasteurianum*, but not *K. pneumoniae*, are cold labile and lose activity rapidly below 5° C. Fe-proteins are monomeric dimers with similar Fe and S^{2-} contents. As with the Mo–Fe proteins, there is a high proportion (about 20%) of acidic amino acid residues which are about twice as abundant as basic residues[11,34]. Although there is a general similarity in composition (Table 4) and a characteristic absence of tryptophan, the compositional relatedness of these proteins is not close.

Electron paramagnetic resonance spectra of the proteins from *C. pasteurianum*[28,29], *K. pneumoniae*[30] and *A. vinelandii*[28] in the reduced form show a plant ferredoxin-like signal of the g=1.94 type below 40 K, although the line shape indicates a more complex structure than spinach ferredoxin. They integrate to 0.2–0.8 electrons per dimer depending on the source of the protein. The oxidised forms of these proteins have no EPR signal. When Mg^{2+} and ATP or ADP are added to the reduced proteins, the symmetry changes from a rhombic to an axial type; other nucleoside triphosphates are inactive. Similar changes in signal symmetry occur if the protein conformation is perturbed by 5 M urea[39]. Titration of the EPR spectrum with ATP showed tight binding of 2 ATP molecules to the protein

Table 4 Amino acid compositions of nitrogenase components from various organisms

Values given are residues per molecular weight of 229,000 for *K.pneumoniae*; 220,000 for *C.pasteurianum*; 270,000 for *A.vinelandii* and 200,000 for *R.japonicum* bacteroids Mo–Fe protein and 66,700 for *K.pneumoniae* and 55,000 for *C.pasteurianum* Fe proteins.

from *C. pasteurianum*[39]; equilibrium dialysis also showed two binding sites[40].

ATP increases the sensitivity of the proteins from *A. chroococcum* or *K. pneumoniae* to O_2-inactivation[41]. With *K. pneumoniae* Fe protein it produces marked changes in sedimentation behaviour and also enhances the reactivity of sulphydryl groups with DTNB[42]. The iron of the protein from *C.pasteurianum* reacts faster with the chelating agent α,α'-dipyridyl in the presence of ATP[43]. A conformational change of the Fe protein produced by ATP binding, presumably alters the symmetry of the iron–sulphur chromophore to a strained configuration, with a more reducing standard potential, from which state electrons are transferred to the Mo–Fe protein. The Mössbauer spectrum of reduced ^{57}Fe protein from *K. pneumoniae* is consistent with one type of Fe cluster of spin state of S=1/2 with the spin equally distributed over the four iron atoms[32]. Oxygen damage gives rise to a spectrum very similar to that of reduced high potential Fe protein of *Chromatium vinosum* (Hipip), a protein which contains an Fe_4S_4 cluster[44]. ATP with Mg^{2+} causes little change in the Mössbauer spectrum.

The UV/visible spectra of the Fe proteins from *K. pneumoniae*[11] and *C. pasteurianum*[15] are very similar, being featureless in the visible region. Oxidation of the protein from *C. pasteurianum* with O_2 or dyes produces a maximum increase in absorption at 420 nm[38]. Similar changes occur in the N_2-fixing system when the deductant is exhausted[45], indicating that it becames oxidised under these conditions. The proteins from *K. pneumoniae* and *C. pasteurianum* have troughs associated with tertiary structure in the ultraviolet and no visible circular dichroism[11,34]. As noted above for the Mo–Fe proteins, the absence of visible CD is unusual for proteins with iron–sulphur chromophores.

Electron donors to nitrogenase. Natural reductants of nitrogenase are ferredoxins and/or flavodoxins. Ferredoxins of N_2-fixing bacteria have redox potentials below −390 mV but range in iron and sulphur content from 2 to 8 atoms per mol depending on their source[4]. A ferredoxin from one organism will usually show reactivity with nitrogenase from other organisms; flavodoxins have three oxidation states; the hydroquinone-semiquinone couple of *A. chroococcum* flavodoxin is the active electron-donating species to its homologous nitrogenase and also to nitrogenase from *K. pneumoniae*[46]. In anaerobic organisms, pyruvate metabolised by the phosphoroclastic system provides both reduced ferredoxin and ATP; formulate or H_2 give only reduced ferredoxin[4]. Chloroplasts which have been heat-treated to inactivate photosystem II can be used as a reductant for nitrogenase *in vitro* when coupled through a ferredoxin or flavodoxin[47]. Reduced viologen dyes[48] or $Na_2S_2O_4$ reduce nitrogenase directly and are widely use *in vitro*.

Interaction of the nitrogenase proteins. Though the separated nitrogenase proteins show evidence of interaction with ATP or reducible subtrates, neither has yet been shown to catalyse any partial reactions. When increasing amounts of the Mo–Fe protein are added to a fixed amount of Fe protein the nitrogenase activity increases from zero to a plateau if phosphate release from ATP is measured[36,49], but a region of inhibition is reached for reducible substrates[8,11,50] (Fig. 1) and $Na_2S_2O_4$ oxidation[49]. The shape of the inhibited part of the activity titration curve differs according to the source of the enzyme. Experiments with complementary proteins from *K. pneumoniae* and *A. chroococcum* indicate that the Fe protein determines the character of the inhibition[41]. The peak of activity occurs at an equimolar ratio of the two proteins for reduction of N_2 or C_2H_2 and for H_2 evolution but not for HCN reduction[36]. Activity

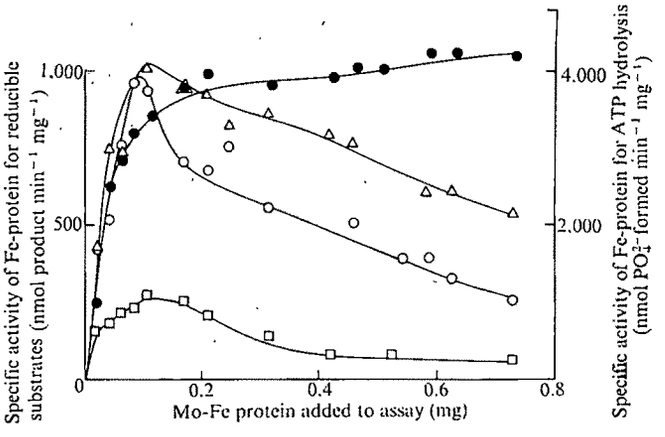

Fig. 1 Nitrogenase activity of *Klebsiella pneumoniae* Fe protein with various concentrations of Mo–Fe protein. Fe protein (42 μg) was assayed with various amounts of Mo–Fe protein (for experimental details see ref. 11). ●——●, ATP hydrolysis; □——□, N_2 reduction; ○——○, C_2H_2 reduction; △——△, H_2 evolution. (After Fig. 10 of ref. 11 but including unpublished data for inorganic phosphate release from ATP.)

titration curves have led to the formulation of the stoichiometry of the nitrogenase complex as 1:1 for *K. pneumoniae*[11] and 1:2 (Fe protein in excess) for *C. pasteurianum*[50]. Ultracentrifuge studies[51] of *K. pneumoniae* components also indicate a 1:1 complex because an equimolar mixture, in the absence of $Na_2S_2O_4$, sediments as a single peak of 12.4S, compared with the 10.4S of the larger Mo–Fe protein. Additional Fe protein sediments independently at its characteristic S value (4.8). $Na_2S_2O_4$ prevents formation of the complex species.

The characteristic Mössbauer and EPR spectra of the two proteins have been used to monitor the oxidation state of both proteins during the pre-steady state and during turnover. EPR experiments have been done with components from *K. pneumoniae*[28,30], *C. pasteurianum*[28,39,50,52,53], *A. vinelandii*[28] and *Chromatium vinosum*[31], but Mössbauer experiments have been made only with *K. pneumoniae*[32,54]. The results obtained with nitrogenase from all four sources are gratifyingly consistent, and an early disagreement whether an oxidative[52] or reductive[28–32] change in the Mo–Fe protein occurs has been resolved[38]. Thus the mechanism schematised in Fig. 2 has a sounder experimental basis than those presented in earlier reviews and articles; essentially it implies that the Mg–ATP complex of reduced Fe protein is the electron donor to the EPR active form (intermediate redox state) of the Mo–Fe protein to which the reducible substrate is bound; it is presented for *K. pneumoniae* nitrogenase because most data are available for these proteins but it is probably substantially true of clostridial and other nitrogenases. A summary of the evidence bearing on the steps in Fig. 2 follows.

(1) The electron donor in *K. pneumoniae* has not been identified but it is probably a flavodoxin or ferredoxin as in other nitrogen-fixing bacteria.

(2) The Fe protein accepts electrons from the donor, and binds Mg–ATP to form a species of altered EPR spectrum[30], tertiary structure[42] and standard potential.

(3) Substrate is bound by the EPR-active form of the Mo–Fe protein at a site which influences the *p*H-dependence of the EPR spectrum. Since it probably involves a transition metal, it is tempting to assign to Mo the substrate binding role[30].

(4) In the steady state, the EPR of the Mo–Fe protein decreases by 90%[30] an the fully reduced species appears in the Mössbauer spectrum, indicating that the reduced Mg–ATP–Fe protein transfers electrons to the Mo–Fe protein-substrate species of intermediate redox state[32]. Consistent with this view, the EPR signal of the Mo–Fe protein returns when reductant ($Na_2S_2O_4$) is exhausted[30].

(5) The Mössbauer spectra of the Fe protein show only slight changes in the functioning enzyme, consistent with some degree of oxidation[32]; the EPR of the reduced form of this protein also persists, though at a lowered intensity[30].

(6) A 1:1 complex with a half-life longer than the half-life of the redox species of its components in the functional enzyme has been assumed in Fig. 2 on the basis of the activity titration[11,36] and sedimentation data[51] indicated earlier.

The oxidised species of the native Mo–Fe protein which has no EPR but a distinctive Mössbauer spectrum, formed *in vitro* by reaction with the dye Lauth's violet, is rapidly reduced by the reduced Fe protein in the presence of ATP[29]. Such oxidised species probably do not participate in enzyme function *in vivo*.

The scheme in Fig. 2 is naturally imperfect: it supplies only a single function for Mg–ATP and accounts for transfer of only one electron from donor to reducible substrate. It also allows only one reductive site on the enzyme complex, when there may be as many as five[71]. But it provides a basis for future hypotheses, which must incorporate the fact that six electrons are transferred to N_2, with the apparent hydrolysis of more than six ATP molecules and without

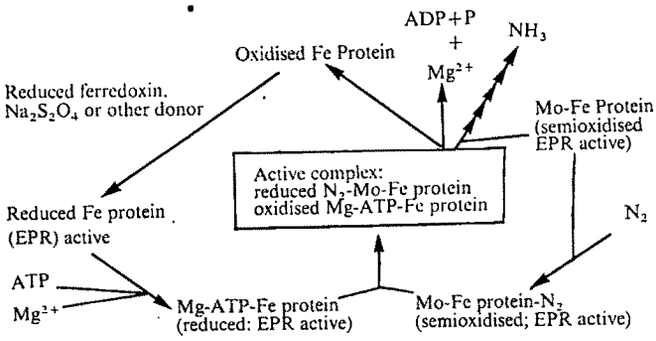

Fig. 2 Schematic representation of events during turnover of nitrogenase. For details see text; (EPR) signifies that the species has an EPR signal; the multiple arrows before NH_3 signify the six electron transfer steps which occur before an identified reduction product is formed.

identified itermediates. Whether the complex, if real, dissociates and reassociates during catalysis: whether the Fe protein is resupplied with ATP or replaced by new Mg–ATP protein are among the many questions that the scheme poses.

Stratospheric sink for chlorofluoromethanes: chlorine atomc-atalysed destruction of ozone

Mario J. Molina & F. S. Rowland

Department of Chemistry, University of California, Irvine, California 92664

Chlorofluoromethanes are being added to the environment in steadily increasing amounts. These compounds are chemically inert and may remain in the atmosphere for 40–150 years, and concentrations can be expected to reach 10 to 30 times present levels. Photodissociation of the chlorofluoromethanes in the stratosphere produces significant amounts of chlorine atoms, and leads to the destruction of atmospheric ozone.

HALOGENATED aliphatic hydrocarbons have been added to the natural environment in steadily increasing amounts over several decades as a consequence of their growing use, chiefly as aerosol propellants and as refrigerants[1,2]. Two chlorofluoromethanes, CF_2Cl_2 and $CFCl_3$, have been detected throughout the troposphere in amounts (about 10 and 6 parts per 10^{11} by volume, respectively) roughly corresponding to the integrated world industrial production to date[3–5,31]. The chemical inertness and high volatility which make these materials suitable for technological use also mean that they remain in the atmosphere for a long time. There are no obvious rapid sinks for their removal, and they may be useful as inert tracers of atmospheric motions[4–6]. We have attempted to calculate the probable sinks and lifetimes for these molecules. The most important sink for atmospheric $CFCl_3$ and CF_2Cl_2 seems to be stratospheric photolytic dissociation to $CFCl_2 + Cl$ and to $CF_2Cl + Cl$, respectively, at altitudes of 20–40 km. Each of the reactions creates two odd-electron species—one Cl atom and one free radical. The dissociated chlorofluoromethanes can be traced to their ultimate sinks. An extensive catalytic chain reaction leading to the net destruction of O_3 and O occurs in the stratosphere:

$$Cl + O_3 \rightarrow ClO + O_2 \quad (1)$$

$$ClO + O \rightarrow Cl + O_2 \quad (2)$$

This has important chemical consequences. Under most conditions in the Earth's atmospheric ozone layer, (2) is the slower of the reactions because there is a much lower concentration of O than of O_3. The odd chlorine chain (Cl, ClO) can be compared with the odd nitrogen chain (NO, NO_2) which is believed to be intimately involved in the regulation of the present level of O_3 in the atmosphere[7–10]. At stratospheric temperatures, ClO reacts with O six times faster than NO_2 reacts with O (refs 11, 12). Consequently, the Cl–ClO chain can be considerably more efficient than the NO–NO_2 chain in the catalytic conversion of $O_3 + O \rightarrow 2O_2$ per unit time per reacting chain[13].

Photolytic sink

Both $CFCl_3$ and CF_2Cl_2 absorb radiation in the far ultraviolet[14], and stratospheric photolysis will occur mainly in the 'window' at 1,750–2,200 Å between the more intense absorptions of the Schumann–Runge regions of O_2 and the Hartley bands of O_3.

We have extended measurements of absorption coefficients for the chlorofluoromethanes to cover the range 2,000–2,270 Å. Calculations of the rate of photolysis of molecules at a given altitude at these wavelengths is complicated by the intense narrow band structure in the Schumann–Runge region, and the effective rates of vertical diffusion of molecules at these altitudes are also subject to substantial uncertainties. Vertical mixing is frequently modelled through the use of 'eddy' diffusion coefficients[10,15–18], which are presumably relatively insensitive to the molecular weight of the diffusing species. Calculated using a time independent one-dimensional vertical diffusion model with eddy diffusion coefficients of magnitude $K \sim (3 \times 10^3)$–10^4 cm^2 s^{-1} at altitudes 20–40 km (refs 10, 15–18), the atmospheric lifetimes of $CFCl_3$ and CF_2Cl_2 fall into the range of 40–150 yr. The time required for approach toward a steady state is thus measured in decades, and the concentrations of chlorofluoromethanes in the atmosphere can be expected to reach saturation values of 10–30 times the present levels, assuming constant injection at current rates, and no other major sinks. (The atmospheric content is now equivalent to about five years world production at current rates.) Lifetimes in excess of > 10 and > 30 yr can already be estimated from the known industrial production rates and atmospheric concentrations[3,5], and so the stratospheric photochemical sink will be important even if other sinks are discovered.

Our calculation of photodissociation rates is modelled after those of Kockarts[19] and Brinkmann[20], and is globally averaged for diurnal and zenith angle effects. The photodissociation rates at an altitude of 30 km are estimated to be 3×10^{-7} s^{-1} for $CFCl_3$ and 3×10^{-8} s^{-1} for CF_2Cl_2, decreasing for each by about a factor of 10^{-2} at 20 km. The appropriate solar ultraviolet intensities at an altitude of 30 km may be uncertain by a factor of 2 or 3 (ref. 21) and we have therefore calculated lifetimes for photodissociation rates differing from the above by factors of 3 or more. The competition between photodissociation and upward diffusion reduces the relative concentration of chlorofluoromethane at higher altitudes and the concentrations should be very low above 50 km. The peak rate of destruction, and formation of Cl atoms, occurs at 25–35 km, in the region of high ozone concentration. The rates of formation of Cl atoms at different altitudes, and the chlorofluoromethane atmospheric lifetimes are sensitive to the assumed eddy diffusion coefficients, as well as to the photodissociation rates.

The major chain processes in the stratosphere involving species with odd numbers of electrons belong to the H (H, OH, HO_2), N (NO, NO_2), and Cl (Cl, ClO) series. (ClO_2 is rapidly decomposed and its concentration is negligible relative to Cl plus ClO.) These odd-electron chains can only be terminated by interaction with one another, although other reactions can convert one series to another. At most altitudes, the first reaction for converting the Cl–ClO odd-electron chain to an even-electron species containing chlorine is the abstraction of H from CH_4, which transfers the odd-electron character to the CH_3 radical:

$$Cl + CH_4 \rightarrow HCl + CH_3 \qquad (3)$$

At stratospheric temperatures the rate constant for Cl atoms[22], for (3) is about 10^{-3} times as fast as (1) and the O_3/CH_4 concentration ratio can make the rate of (3) less than that of (1) by another factor of 10. The Cl atom chain can be renewed by the reaction of OH with HCl (ref. 23):

$$OH + HCl \rightarrow H_2O + Cl \qquad (4)$$

Ultraviolet dissociation by absorption in the range 1,750–2,200 Å can also occur at the higher altitudes. The reaction rate of (4) in the stratosphere depends on the concentration of OH, which is known only roughly. In our estimates, termination of the Cl–ClO chain results from downward diffusion of the longer lived species in the chain (ClO, HCl) and eventual removal by tropospheric processes. The rate of termination thus also depends on diffusion processes and estimates will vary with the choice of eddy diffusion coefficients.

Possible terminations involving the Cl series with itself (for example, $Cl + ClO \rightarrow Cl_2O$) or with one of the others (for example, $Cl + NO \rightarrow NOCl$) normally lead to molecules with appreciable absorption coefficients at longer wavelengths, which are very rapidly dissociated again by the much more intense solar fluxes available there. Thus, even if a molecule which temporarily terminates two chains is formed, at least one of which involves the Cl series, the terminating molecule is rapidly photolysed and both chains are regenerated again.

Under most stratospheric conditions, the slow reactions in both the Cl–ClO and NO–NO_2 chains occur between O atoms and ClO and NO_2 molecules. The two chains are interconnected:

$$ClO + NO \rightarrow Cl + NO_2 \qquad (5)$$

The rate of this reaction in the stratosphere is frequently comparable to that of reaction (2). The overall effect is complex and depends on the relative concentrations of ClO_x, NO_x, O_3, O and OH. Reaction (1) is so rapid that the ClO/Cl ratio is usually > 10, even when Cl is produced by both reaction (2) and reaction (5), so that the overall rate of reaction (2) is not directly affected by the occurrence of reaction (5). As soon as Cl is produced, however, HCl can form by reactions (1) or (3), resulting in the temporary termination of the Cl atom chain. Whether or not the chain is then restarted depends primarily on the concentration of OH. There are substantial ranges of stratospheric altitudes in which neither reaction (3) nor reaction (5) seriously impedes the chain process of reactions (1) and (2).

The initial photolytic reaction produces one Cl atom from each of the parent molecules, plus a CX_3 radical (X may be F or Cl). The detailed chemistry of CX_3 radicals in O_2 or air is not completely known, but in the laboratory a phosgene-type molecule, CX_2O, is rapidly produced and another X atom—probably Cl (or ClO)—is released from $CFCl_2$ or CF_2Cl[21,25]. CX_2O may also photolyse in the atmosphere to give a third and fourth free halogen atom. Thus, each molecule of $CFCl_3$ initially photolysed probably leads to between two and three Cl atom chains, and CF_2Cl_2 probably produces two Cl atom chains when it is photolysed. Initial calculations suggest that F atom chains will be much shorter than Cl atom chains because the reaction of abstraction from CH_4 is much faster for F atoms[26], whereas the reaction between OH and HF is 17 kcalorie mol^{-1} endothermic and will not occur in the stratosphere. We have not yet attempted to analyse the subsequent reaction paths of HF.

Production rates

The 1972 world production rates for $CFCl_3$ and CF_2Cl_2 are about 0.3 and 0.5 Mton yr^{-1} respectively[1,2,5], and are steadily increasing (by 8.7% per year for total fluorocarbons in the United States from 1961–71) (ref. 1). We have not included any estimates for other chlorinated aliphatic hydrocarbons also found in the atmosphere, such as CCl_4 (refs 3 and 4), $CHCl_3$, C_2Cl_4 and C_2HCl_3 for which there is no evidence for long residence times in the atmosphere[27]. If the stratospheric photolytic sink is the only major sink for $CFCl_3$ and CF_2Cl_2, then the 1972 production rates correspond at steady state to globally averaged destruction rates of about 0.8×10^7 and 1.5×10^7 molecules cm^{-2} s^{-1} and formation rates of Cl atoms of about 2×10^7 and 3×10^7 atoms cm^{-2} s^{-1}, respectively. The total rate of production of 5×10^7 Cl atoms cm^{-2} s^{-1} from the two processes is of the order of the estimated natural flux of NO molecules (2.5–15 $\times 10^7$ NO molecules cm^{-2} s^{-1}) involved in the natural ozone cycle[9–12], and of the 5×10^7 NO molecules cm^{-2} s^{-1} whose introduction around 25 km from stratospheric aviation is estimated would cause a 6% reduction in the total O_3 column[10].

Photolysis of these chlorofluoromethanes does not occur in the troposphere because the molecules are transparent to wavelengths longer than 2,900 Å. In fact the measured absorption coefficients for $CFCl_3$ and CF_2Cl_2 are falling rapidly at wavelengths longer than 2,000 Å (ref. 14). The reaction between OH and CH_4 is believed to be important in the troposphere[17,28], but the corresponding Cl atom abstraction reaction (for example, $OH + CFCl_3 \rightarrow HOCl + CFCl_2$) is highly endothermic and is negligible under all atmospheric conditions.

Neither $CFCl_3$ nor CF_2Cl_2 is very soluble in water, and they are not removed by rainout in the troposphere. Details of biological interactions of these molecules in the environment are very scarce because they do not occur naturally (except possibly in minute quantities from volcanic eruptions)[29], but rapid biological removal seems unlikely. The relative insolubility in water together with their chemical stability (especially toward hydrolysis)[30] indicates that these molecules will not be rapidly removed by dissolution in the ocean, and the few measurements made so far indicate equilibrium between the ocean surface and air, and therefore a major oceanic sink cannot be inferred[3].

It seems quite clear that the atmosphere has only a finite capacity for absorbing Cl atoms produced in the stratosphere, and that important consequences may result. This capacity is probably not sufficient in steady state even for the present rate of introduction of chlorofluoromethanes. More accurate estimates of this absorptive capacity need to be made in the immediate future in order to ascertain the levels of possible onset of environmental problems.

As with most NO_x calculations, our calculations have been based entirely on reactions in the gas phase, and essentially nothing is known of possible heterogeneous reactions of Cl atoms with particulate matter in the stratosphere. One important corollary of these calculations is that the full impact of the photodissociation of CF_2Cl_2 and $CFCl_3$ is not immediately felt after their introduction at ground level because of the delay required for upward diffusion up to and above 25 km. If any Cl atom effect on atmospheric O_3 concentration were to be observed from this source, the effect could be expected to intensify for some time thereafter. A lengthy period (of the order of calculated atmospheric lifetimes) may thus be required for natural moderation, even if the amount of Cl introduced into the stratosphere is reduced in the future.

This research has been supported by the US Atomic Energy Commission. We acknowledge a helpful discussion with Professor H. S. Johnston.

X-ray spectrum of NP0532

THERE is a change in the X-ray spectral index of the Crab pulsar NP0532 near 10 keV (refs 1 and 2). We here examine this in a more quantitative fashion than before, using most of the available published data, together with some unpublished data (Table 1). The pulsed fraction is the ratio of the pulsed radiation to total radiation; data published as the ratio of the pulsed to unpulsed components have been duly corrected. The unpulsed reference level has been determined according to Ducros *et al.*[3] and where other workers have used a significantly different convention, these data have been corrected. We believe that all data (31 points), can be validly compared. Other results, not considered here[2,4,5], are generally in agreement with the data we have used. The use of the pulsed fraction as the basic spectral quantity allows the low energy spectrum to be treated independently of interstellar absorption because it is the same for both the pulsed and unpulsed components.

A multiparameter, nonlinear, weighted routine was used to fit least squares (see refs 6 and 7). This program yields values of the unknown parameters of any generalised mathematical model which is applied to input data, together with relevant statistics, including the approximate 95% confidence interval for each parameter and the reduced χ^2 χ^2_{rt}, the value of χ^2 per degree of freedom) for the successful fit.

Any change in spectral slope will probably be gradual, perhaps spanning a decade or more. The precision of the available data is, however, such that a sharp break can be assumed for the source model, at least initially. This is also analytically simple. The assumption of identical spectral indices above the break energy is justified in a similar way (see also ref. 8). The pulsed fraction F as a function of energy E (keV) is thus given by

$$F(E) = \begin{cases} A, & E \geq E_B \\ B \exp(-\beta\lambda^2) E\gamma-\alpha, & E < E_B \end{cases}$$

where A is the fraction (assumed constant) above the break

Table 1 Summary of the data used*

Source	Energy range (keV)	No. of data points

*Values are derived for the size and location of the break, assuming identical spectral indices for the pulsar and the nebula above the break energy and taking into account the effect of interstellar dust scattering on the pulsed radiation below approximately 2 keV. *a*, Unpublished data (C. Jehanno, C. Cheron, J. Leloup, R. Rothenflug, and R. Thomas).

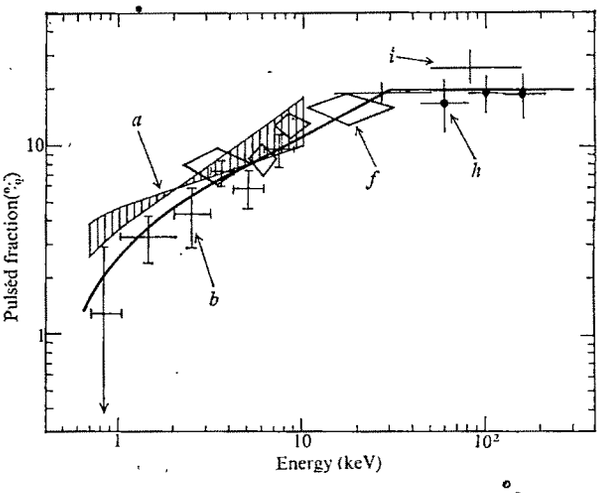

Fig. 1. The X-ray pulsed fraction of NP0532, showing the least squares fit. A selection of the data listed in Table 1 is displayed. Notation as in Table 1. Solid curve, line of best fit.

energy E_B, α and γ are the spectral indices of the pulsar and total emission energy respectively, $\beta(Å^{-2})$ is the interstellar grain scattering coefficient, λ is the photon wavelength (Å), and $B = A \exp(\beta\lambda_B^2)E_B\alpha^{-\gamma}$ where $\lambda_B = hc/E_B$. The effect of scattering is felt only below about 2 keV, and so β is left a fixed parameter. An X-ray measurement of this quantity, and thus of the amount of dust in the line of sight should, however, become possible with further improvement in the precision of 0.5 and 2 keV data. Consequently, two fixed values of β were tried: $\beta = 0$ (no scattering) and $\beta = 2 \times 10^{-3}$ Å^{-2} (as expected in the direction of the Crab)[9]. The quantities α, A and E_B were left as free parameters, with $\gamma = 1.0$. The computational results are summarised in Table 2 and the best fit is drawn through the data of Fig. 1.

The choice of β makes little difference to the quality of the fit, but using $\beta = 2 \times 10^{-3}$ Å^{-2} makes the spectral index and

Table 2 Computational results for parameters used

$\beta(Å^{-2})$	χ_r^2	α	E_B(keV)	A(%)
0	0.75	0.35±0.15	24±13	19± 4
2×10^{-3}	0.72	0.44±0.13	30±17	20± 4

the break energy slightly greater. The large error in E_B, together with the acceptable χ_r^2 value, reflects the lack of precision of the data. A sharp break at 30 ± 17 keV satisfies the data well, although statistically improved data will probably modify this conclusion in the future.

The value $\alpha = 0.44 \pm 0.13$ is derived relative to a total emission index of $\gamma = 1.00$. Taking the error in γ to be ± 0.1 will yield a final result of $\alpha = 0.4 \pm 0.2$. This result is not inconsistent with the suggestion[10] that the pulsar X-ray index may be identical to the Nebula radio index of 0.26, indicating a common parent electron population in regions with different magnetic fields. A spectral index of between 0.4 and 0.5, extrapolated toward the optical region, agrees, however, much better with the known pulsar optical spectrum than does an index of 0.26 or 0.2 (ref. 1).

The present fit shows that there is no necessity to postulate a further sharp change of spectral index in NP0532 between 1.5 and 3 keV as suggested by Rappaport *et al.*[4].

The idea that the decrease in the pulsed fraction below the break is attributable entirely to interstellar scattering (ref. 11) was tested. The resulting fit was unacceptable ($\chi_r^2 = 2.7$) and the derived value of $\beta = (1.6 \pm 0.9) \times 10^{-2}$ Å^{-2} was an order of magnitude higher than optical measurements imply (ref. 9), regardless of the grain model assumed. This model can therefore be rejected (see also refs 3 and 9).

Variations of the total emission spectral index of the Nebula with energy[2], are relevant. Our assumption that the total emission spectral index is given by $\gamma = 1.0 \pm 0.1$ remains valid for energies up to 60 keV (refs. 1 and 2), a fact which lends confidence to the derived value of $\alpha = 0.4 \pm 0.2$ for the pulsar below about 30 keV. The increase in γ to 1.46 ± 0.11 above 60 keV brings into question the assumption that $\alpha = \gamma$ for $E > E_B$, which would imply a second pulsar break at 60 keV, for which there is no evidence. In our opinion, however, the use of the analytically simple model presented here is justified at this time by the relatively poor statistics of the higher energy pulsar data.

Charge composition of cosmic rays between 4 and 100 GV

SEVERAL groups have reported the energy dependence of the charge composition of cosmic-ray nuclei with $Z \geq 3$ (refs 1–5). The results suggest that the ratio of the numbers of nuclei in groups L and M (defined in Table 1) decreases as the rigidity increases. At 100 GV the ratio is about 25% lower than the value below 10 GV. There is, however, no general agreement about the variation with rigidity of the ratio of VH nuclei to M nuclei; a variable ratio would be evidence for the existence of more than one basic acceleration mechanism, because both charge groups are thought to consist mainly of particles coming directly from the sources. The largest variation in the ratio of VH to M nuclei is reported by Ormes and Balasubrahmanyan[1]. We report here the measurement of the ratios of L nuclei to M

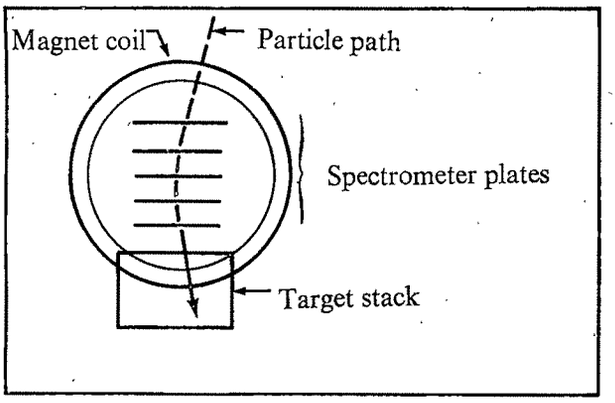

Fig. 1 Schematic representation of the detector system indicating the location of the five spectrometer plates and the target emulsion stack.

nuclei and of VH nuclei to M nuclei using a magnetic spectrometer. Our results are based on two balloon flights, the first from Palestine, Texas, on August 23, 1969, and the second on November 13, 1970, from Parana, Argentina. The combined exposure factor for these flights was 273 cm^2 sr s at an average altitude of 3 g cm^{-2}.

The apparatus[6] consists of an emulsion block and five double-coated glass plates arranged in the field of a superconducting magnet (Fig. 1). Events were found by area scanning the target block and rigidities were measured by tracing particles through the emulsion-coated glass plates. The scanning efficiency was >95%. The process of rigidity measurement has a resolution of

Table 1 Number of nuclei as a function of charge group and rigidity

	Rigidity interval (GV)

12% at 5 GV and 35% at 100 GV (ref. 6); it is very straightforward (using a 14-constraint least squares fit to each track) and does not rely on assumptions concerning observed spectrum. Alignment and resolution information are obtained by turning off the magnet in flight to calibrate the system with tracks which are straight except for Coulomb scattering. A computer-controlled microscope with a measuring accuracy of ± 2.5 μm, was used to measure the trajectories. A total of 791 tracks of nuclei with $Z \geq 3$ were located during the area scan. This paper is based on the 625 events which have so far been measured completely. In

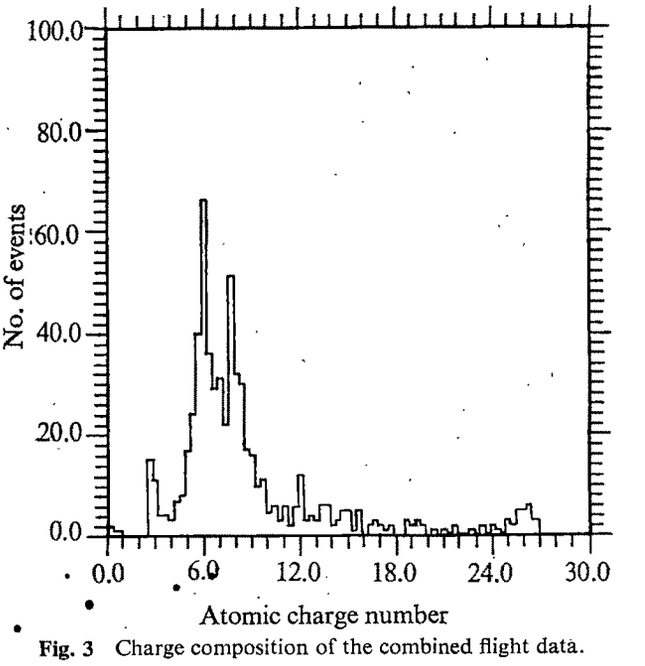

Fig. 3 Charge composition of the combined flight data.

Fig. 2 we present the rigidity spectra of nuclei with $Z \geqslant 3$ gathered during the two flights. There is close agreement between the energy spectra of Texas and Argentina flights at rigidities above 12 GV, where solar modulation should be negligible. The absolute flux value agrees with that of Anand *et al.*[7]. A maximum likelihood analysis gives a spectral index of -2.6 ± 0.1, which is consistent with other observations in this region.

Charge measurement was carried out using a television microscope to measure track area. The charge distribution obtained with the microscope photometer is shown in Fig. 3. The resolution is 0.4 charge units at carbon and ~ 1.0 charge unit at iron. Clearly, there is some contamination of L nuclei from the neighbouring carbon peak. This contamination should be independent of rigidity.

Figures 4 and 5 show the charge composition as a function of rigidity. The data are uncorrected for the 3 g cm^{-2} of air, 3 g cm^{-2} of emulsion and 1 g cm^{-2} of glass above the scan line.

Measurement of spectral indices for the individual charge groups is difficult at rigidities below 12 GV because of very

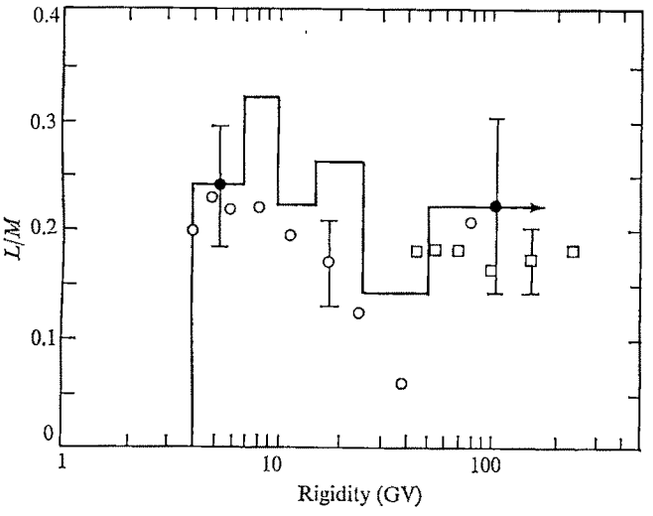

Fig. 4 Ratio of L nuclei to M nuclei as a function of rigidity. ○, Smith *et al.*[4]; □, Juliusson *et al.*[2].

strong solar modulation during the Texas flight and a geomagnetic cutoff at 12 GV during the second flight. Instead of measuring separate spectral indices we have measured the dependence on rigidity of the ratios of the charge groups. This rests on the implicit assumption that effects arising from solar modulation and geomagnetic cutoff do not depend on charge in the range 4–12 GV. The analysis of the dependence on rigidity of the charge ratios was carried out by using the M nuclei at a given rigidity to predict the numbers of VH or L nuclei. For a given charge group (VH, for example) a charge ratio relative to the M group $R = a\rho^{-\Delta K}$ is assumed. The constant a is chosen so that the number of expected VH (or L) nuclei equals the number of observed VH (or L) nuclei. The parameter ΔK is the difference in spectral indices ($\Delta K > 0$ means VH is flatter than M). In each rigidity interval

$$\langle VH \rangle_{\text{expected}} = R(\bar{\rho}, \Delta K)\,(M)_{\text{observed}} \qquad (1)$$

Using the values of $\langle VH \rangle_{\text{exp}}$ and $(VH)_{\text{obs}}$ a pseudo-likelihood function is evaluated for a given value of ΔK by multiplying the Poisson probabilities of all the rigidity intervals.

$$L(\Delta K) = \prod_{\text{rigidity intervals}} P(\langle VH \rangle_{\text{exp}}, (VH)_{\text{obs}}) \qquad (2)$$

where P is the Poisson probability of observing $(VH)_{\text{obs}}$ when VH_{exp} is the expected number of counts.

The effects of mixing of data from adjacent rigidity intervals

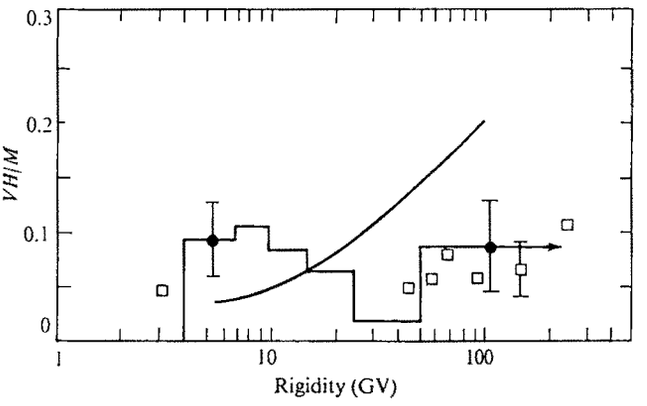

Fig. 5 Ratio of VH nuclei to M nuclei as a function of rigidity. □, Juliusson *et al.*[2]; curve, best fit for VH/M after Ormes and Balasubrahmanyan[1].

are small for the magnetic spectrometer. The uncertainty in measured rigidity is easily determined by least-squares error propagation. The largest correction would be to the highest rigidity bin in the ratio of VH nuclei to M nuclei. The ratio should be lowered by ~ 0.01 which is negligible. Although such corrections may be significant for other less accurate energy-measuring devices they can be neglected in this analysis.

The likelihood analysis yields a spectral index difference $\Delta K = -0.2 \pm 0.2$ for the VH/M ratios. Our result is in strong conflict with that of Ormes and Balasubrahmanyan[1], $+0.57 \pm 0.14$, which has a likelihood of 0.1% relative to our most probable result. This result is not inconsistent with the observations of Juliusson *et al.*[2], Webber *et al.*[3] and Atallah *et al.*[4] as can be seen in Fig. 5. Our experiment itself, however, reveals no evidence of a difference between the VH spectrum and the M spectrum. The L/M analysis gives a spectral index difference $\Delta K = +0.12 \pm 0.4$, consistent with the observations of all other observers but also consistent with zero. It is worth noting again that our L sample is contaminated with 20–25% of carbon nuclei. The (LH + MH)/M ratio gave a spectral index difference of $-0.14^{+0.1}_{-0.16}$.

Since the area scan is 95% efficient, the identification of particles is independent of energy and the rigidity measurement relies only on the solution of the Lorentz-force equation, this experiment can be expected to be exceptionally free of energy–charge biases. We find no evidence that the VH spectrum is steeper than the M spectrum. The difference in spectral indices is -0.2 ± 0.2 (minus meaning VH is steeper than M). Observations of the L and (LH + MH) fluxes relative to the M flux is consistent with the observations of the Berkeley and Chicago groups.

Isotropy of the arrival directions of ultra high energy cosmic rays

THERE has been little success in the search for anisotropies in the arrival directions of ultra high energy cosmic rays. Data on 50 events of very high energy, having an arrival direction which is 'not obviously isotropic', have however, been collected by the Sydney extensive air shower group[1]. The data were recorded over a period of 5 yr and, as the world total of such events is likely to increase only rather slowly, this seems to be the appropriate time to combine these data with comparable data from the Northern Hemisphere arrays operated at Cornell (United States), Haverah Park (United Kingdom) and Volcano Ranch (United States). The arrival directions of 87 showers with primary energies above a few times 10^{19} eV are discussed here. It is shown that there are no large deviations from an isotropic distribution and it is concluded that the ultra high energy cosmic rays are most likely to come predominantly from extra-Galactic sources.

Table 1 Comparison of observed and predicted number of equi-event areas

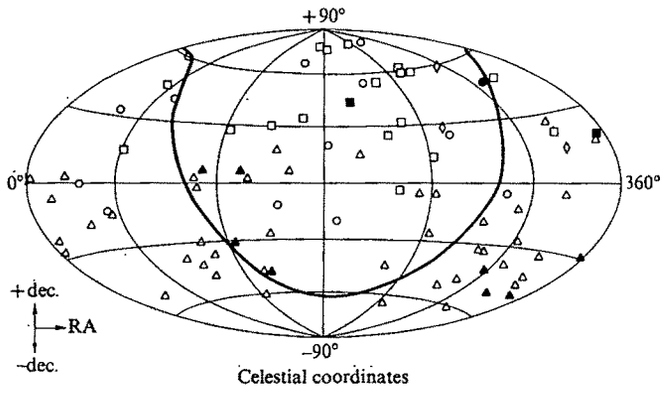

Fig. 1 Aitoff equal area projection of 87 events[1,3-6] in celestial coordinates. Solid line, Galactic plane; triangles, Sydney observations (50); circles, Volcano Ranch observations (14); squares, Haverah Park observations (20); diamonds, Cornell observations (3). Events which may have primary energies above 10^{20} eV have the appropriate symbol filled. Energy assignment has been made using a model of shower development described by Hillas (see ref. 4 for details).

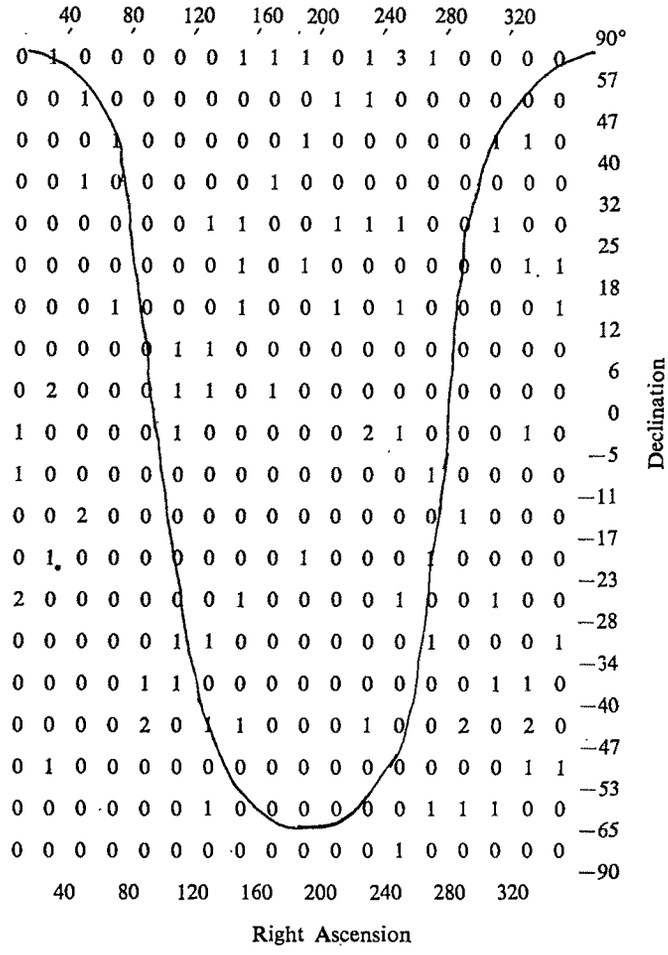

Fig. 2 Equi-event plot in celestial coordinates of 84 events[1,4-6]. Areas of 20° RA × $(\delta_i - \delta_j)$° dec. are expected to contain equal numbers. The values of δ_i, δ_j are listed at the right hand side of the figure and are deduced from the declination distributions[1,5,6] by assuming that the exposure time of each experiment is proportional to the number of events recorded. The solid line represents the Galactic plane.

The events discussed by the Sydney group are all of higher primary energy than a threshold level which is claimed to be 1.5×10^{19} eV. The assignment of energy is subject to the energy conversion which is used to relate the measured number of muons in their showers to primary energy. Less ambiguity in the threshold of selection of data from different arrays is therefore introduced if only those events are included which were recorded at an intensity less than a certain value. Using the energy spectrum given by the Sydney group[2] their threshold intensity is found to be 4.62×10^{-15} m^{-2} s^{-1} sr^{-1}. Events from the Cornell, Haverah Park and Volcano Ranch data banks were therefore selected only if they were recorded at intensities less than this value. Of the additional 37 events recorded by the Northern Hemisphere experiments, three were recorded at Cornell (refs 3, 4 and J. Delvaille, personal communication), 20 were recorded at Haverah Park[5,6] and 14 at Volcano Ranch. The directional uncertainty varies slightly between experiments but is believed to be better than 3×10^{-3} sr for all 87 events.

All 87 events are shown on an Aitoff equal-area projection in celestial coordinates (Fig. 1). The Galactic plane is also indicated. It is clear that there is no evidence of significant clustering of events. In particular the region close to the Galactic plane shows no indication of the excess which could be

expected if the sources of high energy cosmic rays were objects (for example, pulsars) which are strongly clustered on the Galactic plane. Statistical support can be given to the conclusion that the data are consistent with isotropy if a rectangular right ascension (RA)–declination (dec.) plot is divided into areas within which the number of observed events would be expected to be equal. For the Volcano Ranch, Haverah Park and Sydney arrays sufficient data have been published[1,6,7] at low energies (10^{17}–10^{18} eV), where the evidence of isotropy is very strong, to enable such an 'equi-event' diagram to be constructed, and Fig. 2 shows 360 'equi-event' areas. The mean number of events expected per area is 0.234 and the number of areas with 0, 1, 2, 3. . . events is compared with the predicted number in Table 1 assuming that the arrival directions are randomly distributed. The data are clearly consistent with isotropy of arrival directions and contain no evidence for the existence of point sources of ultra high energy cosmic rays.

It seems likely that primary cosmic rays in the energy region in question ($E_p \geq 2 \times 10^{19}$ eV) have atomic masses $1 \leq A \leq 56$, but no experimental data are available to enable this range to be narrowed. Karakula *et al.*[8] have estimated the extended anisotropies which would be likely to arise in various Galactic magnetic field models if the cosmic ray sources were concentrated in the disk or the spiral arms of the Galaxy, and if the primary particles were protons. Comparing the data of Fig. 1 with the distributions predicted by these authors for protons of 10^{19} eV and several reasonable Galactic field models, we conclude that if the primaries are protons then ultra high energy cosmic rays are predominantly of extra-Galactic origin.

If the primary particles at these energies are iron nuclei then the situation is not quite so clear cut. For a model in which the Galactic field is longitudinal but has opposite orientations above and below the Galactic plane, a strong peak is predicted[9] in the direction of the inward spiral arm (RA = 308°, dec. = 35°) for iron nuclei of momentum $> 2.10^{19}$ eV/c, which is clearly in contradiction with the observations. For a simple longitudinal field, which seems to be favoured at the present time[10], some extra-Galactic contribution (probably greater than 30%) seems to be necessary. We therefore conclude that even if the primary particles are iron nuclei a significant fraction of them (> 30%) come from extra-Galactic sources.

The data discussed in this paper include about 11 events with a primary energy of more than 10^{20} eV (Fig. 1) but it is important to note that the absence of a cutoff in the energy spectrum[1,5,6] is not evidence in favour of a Galactic origin for them. Stecker[11] has pointed out that the absence of a cutoff implies only that the lifetimes of these cosmic rays are significantly less than the age of the Universe, and consequently that sources in the local 'super-cluster' of galaxies must be considered possible.

NO and O_3 measurements in the lower stratosphere from a U-2 aircraft.

AIRBORNE nitric oxide and ozone detectors have been carried on aircraft flights over the west coast of the United States to obtain *in situ* measurements of nitric oxide and ozone at altitudes up to 21 km. Results from two of these flights—December 6, 1973 from 1100 to 1430 local time (1900 – 2230 UT) and December 18. 1973 from 1030 to 1430 local time (1830–2230 UT)—are presented here. The experimental platform was one of two U-2 aircraft used in the NASA Earth Resources Aircraft Project at Ames Research Center, Moffett Field, California.

The nitric oxide instrument is a chemiluminescent detector based on the luminescent reaction of nitric oxide with excess ozone in a flow reactor. The photon count rate signals from the detector are proportional to the atmospheric nitric oxide mixing ratio and to the STP flow rate of the atmospheric sample. Two different calibrator flow rates from an on-board NO/N_2 calibrator bottle provide periodic instrument sensitivity checks. The zero level was periodically measured by mixing the excess ozone with the atmospheric sample upstream of the reactor. Signals were derived from two linear count rate circuits, each having a time constant of about 1 s. An automatic cycle timer sequenced the instrument through the measure, calibrate and zero level modes for 3 min each. The sensitivity of the nitric oxide detector for the measurements reported here is 0.025 parts in 10^9 by volume.

Ozone concentration measurements are based on the absorption of the Hg line at 2,537 Å in the Hartley continuum. The unattenuated mercury lamp intensity at 2,537 Å was determined by routing the atmospheric sample flow over a catalytic reactor which removes all the ozone present. The instrument operates on a cycle of 10 s, 5 s each for the absorbed and unattenuated beam measurements. Beer's law was used to extract the ozone partial pressure using an optical absorption coefficient of 306 cm^{-1} atm^{-1}; the absorption tube is 71 cm long. Pressure and temperature corrections were applied to the instrument readout to derive the partial pressure of atmospheric ozone. The instrument is a commercial unit that was especially adapted for use in the U-2 experimental system. The rated sensitivity is 3 nbar partial pressure of ozone.

A ram inlet port of diameter 1 inch brings the air sample flow into the aircraft. Flexible stainless steel lines connect the instrumentation mainfold to the inlet and outlet ports. Typical in-flight air flow rates are 30 STP min^{-1} to the nitric oxide detector and 0.3 STP min^{-1} to the ozone detector. Motorised valves in the manifold isolate the instruments from the atmosphere and from each other up to an altitude of 12 km, at which point the valves are opened by the pilot and measurements commence. Thereafter the system operation is fully automatic. The environment in the experimental bay of the aircraft during data gathering was maintained at approximately 45° F and 4 pound $inch^{-2}$ absolute. The true air speed of the aircraft was 400 knots.

Data from the two instruments were recorded on magnetic tape once a second and the outputs of various pressure, temperature and flow sensors were recorded every 10 s. Graphic

displays of the raw nitric oxide and ozone data were prepared from the magnetic tape. Analysis of the data was carried out from the graphic outputs.

Figure 1 shows results obtained on the flights of December 6 and December 18, 1973 at longitude 122°W and latitudes as indicated. Conversion to nitric oxide number densities was done using the measured sample air flow, calibrator flow and calibrator nitric oxide mixing ratio. The nitric oxide number densities given in the legend to Fig. 1 are average values observed at 21 km over the entire flight segment at that altitude for each date. The average nitric oxide count rates are typically 600, 750, and 1,200 counts s^{-1} over the 3-min zero, measure and calibrate

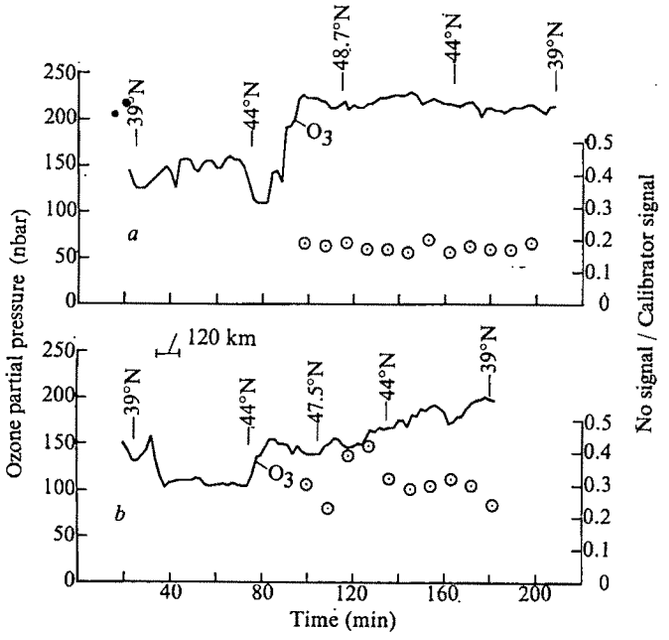

Fig. 1 Measurements *in situ* of nitric oxide and ozone from a U-2 aircraft at 18 and 21 km altitude at longitude 122° W. *a*, December 18, 1973, $[NO]_{ave} = 1.3 \pm 0.6 \times 10^8$ cm^{-3}; *b*, December 6, 1973, $[NO]_{ave} = 2.2 \pm 1.1 \times 10^8$ cm^{-3}. Lower part of each curve (left) corresponds to 18 km altitude, upper part (right) to 21 km.

cycles, respectively. The statistical errors, due to the photon count rates, in the nitric oxide data points of Fig. 1 amount to only about ± 6%. The larger part of the error limits given for the nitric oxide number densities are from estimated uncertainties of ± 5% in the sample and ± 20% in the calibrator flow rates and ± 20% in the calibrator mixing ratio.

The measured loss of nitric oxide in the inlet flow lines is less than 5%; no correction has been made for this. We also measured the loss of ozone in the inlet lines in the laboratory as a function of time from the start of flow of an ozone sample through the lines. The loss is 33% of the input ozone at 30 min decreasing linearly with time to 16% at 210 min. After the appropriate correction for the measured ozone line loss, the estimated uncertainty in the ozone data is ± 20%, of which ± 15% is due to systematic errors.

Data taken at 18 km for nitric oxide are not shown. A system conditioning, indicated by changing calibrator levels, occurred during the first hour of flight. After 1 h the two calibrator levels and their ratio stabilised at values close to those observed in the laboratory before and after the flight. Modifications are in progress to correct this difficulty.

Our measurements of nitric oxide concentrations are in agreement with another chemiluminescent measurement made in the same altitude range[1]. But our measured concentrations are lower, by a factor between three and ten, than recently reported optical measurements[2,3].

We thank M. A. Knutson and R. Danielson of the NASA Earth Research Aircraft Project for help. This work is part of a NASA program, partially supported by the Climatic Impact Assessment Program of the US Department of Transportation.

Temperature, fossil CO_2 accumulation and carbonate ion concentration of the oceanic mixed layer

Several authors[1-4] have recently suggested that there will be a dramatic accumulation of fossil CO_2 in the oceanic mixed layer by the end of this century. If these calculations are correct the predicted increases in the atmospheric partial pressure of carbon dioxide (p_{cd}) and in the total concentration of carbon dioxide species in the mixed layer ($C\tau$) do not imply catastrophic decreases in the carbonate ion concentration[1,3] at 25° C (ref. 5). Two important points remain unresolved, however, and they require further clarification.

The first point concerns the relative merits of the various mixing models. The earlier calculations[5] raise doubts about the validity of the more pessimistic mixing models[1-4] because they indicate that a system reasonably close to equilibrium can only accommodate the predicted $C\tau$ and p_{cd} values if the carbonate alkalinity ($CA = (HCO_3^-) + 2(CO_3^{2-})$) is allowed to increase. This implies either that the reaction

$$CO_2 . H_2O + CO_3^{2-} \rightleftharpoons 2HCO_3^- \quad (1)$$

is not the only process involved in the assimilation of fossil CO_2 in the mixed layer, or that the mixed layer itself is grossly out of equilibrium with the atmosphere. Neither conclusion is consistent with the assumptions of the mixing models[1-3].

A more realistic approach is to explicitly confine the assimilation process to reaction (1) so that CA remains constant and to assume a reasonable measure of equilibrium between the atmosphere and the mixed layer. The concentrations of the carbonate and bicarbonate ions in the mixed layer can then be calculated from the equations derived by Park[6]:

$$c_1 = (CO_2.H_2O) = \alpha p_{cd} \quad (2)$$

$$c_2 = (HCO_3^-) = (X - K_3' c_1)/4 \quad (3)$$

$$c_3 = (CO_3^{2-}) = (4CA + K_3' c_1 - X)/8 \quad (4)$$

$$\text{where } X = ((8CA + K_3' c_1) K_3' c_1)^{1/2} \quad (5)$$

and K_3' is the equilibrium constant for reaction (1). The values of p_{cd} predicted by various workers are in good agreement with one another[3] as they must take due account of the increases observed to the present day. Calculations based on these equations (Skirrow and Whitfield, in preparation) confirm that those models[1-4] which suggest that 25% of the injected fossil CO_2 will reside in the mixed layer, represent systems grossly out of equilibirum with the atmosphere. The model of Broecker

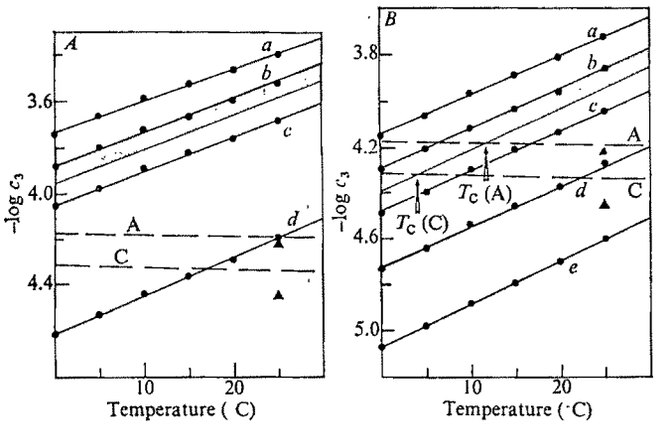

Fig. 1*A*, Variation of carbonate ion concentrations with temperature in 1974 when $p_{cd} = 330 \times 10^{-6}$ atm. Solid lines, seawater values calculated from equations (2) and (4) with the carbonate alkalinities (meq l^{-1}): *a*, 3.0; *b*, 2.5; *c*, 2.0; *d*, 1.0. Shaded area, typical oceanic range. Dashed lines, the carbonate ion concentrations in equilibrium with aragonite (A) and calcite (C) calculated from equations (8) and (7) respectively. ▲, Carbonate ion concentration in equilibrium with aragonite[7] (upper point) and with calcite[7] (lower point). *B*, Variation of carbonate ion concentrations with temperature in 2050 when $p_{cd} = 996 \times 10^{-6}$ atm (ref. 3) with carbonate alkalinities (*CA* meq l^{-1};*a*, 3.0; *b*, 2.5; *c*, 2.0; *d*, 1.5, *e*, 1.0. T_c is the critical temperature at which the carbonate ion concentration of the sea water equals that in equilibrium with aragonite, T_c (A); or calcite, T_c (C); at the saturation point. The values indicated are for $CA = 2.25$ meq l^{-1}, the lowest value normally encountered in the oceans. Other features are as defined for Fig. 1A.

et al.[7], on the other hand, gives an accurate picture of the surface waters in equilibrium with the atmosphere, and predicts that only about 5% of the accumulating fossil CO_2 remains in the mixed layer. Since this layer, by definition, equilibrates fairly rapidly with the atmosphere the model defined by equations (2) to (5) should give the more realistic picture of the effect of increases in atmospheric CO_2 on the chemistry of the mixed layer. This model will be used to discuss the second point: the influence of temperature and carbonate alkalinity on the concentration of carbonate ions in ocean surface waters.

So far, calculations concerned with the dissolution of calcium carbonate have either made no specific mention of the ambient temperature[1-3] or they have been confined to 25° C, a temperature typical of tropical surface waters[6,7]. This bias has arisen primarily because higher latitude waters only represent a relatively small proportion of the Earth's ocean surface. In addition the prospect of calcium carbonate dissolution naturally focuses immediate attention on the fate of the tropical coral reefs. The solubilities of both carbon dioxide and of calcium carbonate in seawater increase, however, as the temperature falls, so that temperate waters will be more sensitive to increases in the value of p_{cd}.

Since the salinity effect is small over the range typically encountered in the open oceans (30–35‰) the values of α given by Murray and Riley[8] at a chlorinity of 19‰ (approximately 35‰ salinity) can be used to calculate c_1 from equation (2) for the appropriate temperature and p_{cd}. This value can then be used in equation (4), together with the appropriate value of K_3' calculated from the data of Lyman[9], to give the carbonate ion concentration at any particular temperature and carbonate alkalinity. In previous calculations[6] (Skirrow and Whitfield, in preparation) the carbonate alkalinity has ranged from 2.2–2.9 meq l^{-1} although the span 2.2–2.5 meq l^{-1} is more typical of the open ocean[10].

The carbonate ion concentration has been calculated from equations (2) and (4) as a function of temperature and carbonate alkalinity for the present day (Fig. 1*A*), and for the year 2050 (Fig. 1*B*) when, according to Zimen and Altenhein, p_{cd} will attain its maximum value.

The concentration of carbonate ions in equilibrium with calcite or aragonite at the saturation point can be calculated from the relationship

$$(CO_3^{2-}) = K_{sp}'/(Ca^{2+}) \quad (6)$$

where K_{sp}' is the apparent solubility product of the relevant carbonate mineral in sea water. According to Ingle *et al.*[11]

$$K_{sp}'\text{ (Calcite)} = (1.390 - 3.096 \times 10^{-3}\, T^\circ\text{C}) \times S \times 10^{-8} \quad (7)$$

As the solubility product of aragonite is pure water is approximately 0.14 logarithmic units higher than that of calcite[12] the corresponding equation for aragonite would be

$$K_{sp}'\text{ (Aragonite)} = (1.919 - 3.096 \times 10^{-3}\, T^\circ\text{C}) \times S \times 10^{-8} \quad (8)$$

Carbonate ion concentrations at saturation, derived from these equations assuming $(Ca^{2+}) = 10$ mmol l^{-1}, are shown in Fig. 1*A* and *B*. Seawaters with carbonate ion concentrations lying above these lines will remain supersaturated with respect to the appropriate mineral, whereas those lying below the line will approach saturation. Although the calculations confirm earlier statements[5] that tropical waters will remain supersaturated throughout, they do indicate that by the year 2050 temperate waters with a mean annual temperature of 10° C (in general[13] those north of latitude 50° N and south of latitude 50°S) will have reached the saturation point for aragonite (Fig. 1*B*). The concentration of carbonate ions will not fall below this level, because the dissolution of carbonate minerals will absorb any additional carbon dioxide[7]:

$$CaCO_3(S) + CO_2\,H_2O \rightleftharpoons Ca^{2+} + 2HCO_3^- \quad (9)$$

This reaction increases both the carbonate alkalinity and the calcium ion concentration and so the system is effectively buffered. These parameters would also increase as the result of enhanced weathering of terrestrial rocks which should become noticeable as the value of p_{cd} rises in the atmosphere.

Using the data of Zimen and Altenhein[3] the calculations used in constructing Fig. 1*B* can be repeated and the critical saturation temperature (T_c, Fig. 1*B*) can be calculated at the end of each decade for seawaters with a particular carbonate alkalinity. All waters with a mean annual temperature less than T_c are likely to approach the saturation level for the mineral specified. The resulting curves (Fig. 2) indicate that, for $CA = 2.25$ meq l^{-1}, waters with mean annual temperatures greater than 5° C are likely to remain supersaturated with respect to calcite and those with temperatures greater than 12° C will remain super-

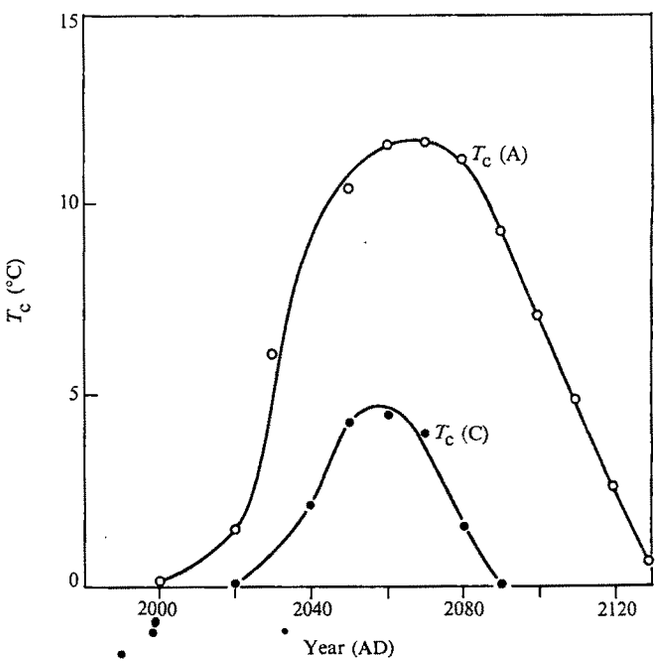

Fig. 2 The variation of the critical saturation temperature for aragonite, T_c (A); and calcite, T_c (C); over the next one and a half centuries calculated from predicted variations in p_{cd} (ref. 3) for seawater with a carbonate alkalinity of 2.25 meq l^{-1}.

saturated with respect to aragonite. The effect is transient, with the time at saturation point increasing as the temperature falls. The detailed picture is of course critically dependent on the solubilities of the various carbonate minerals. Higher[14] and lower[7] values than those given by equations (7) and (8) have been reported for the solubility of calcite and aragonite. A full analysis will become possible only when we have a clearer idea of the values of these parameters at low temperatures.

Hot spot and trench volcano separations

WE suggest that the distribution of separations between trench volcanoes located along subduction zones reflects the depth of partial melting, and that the separation distribution for hot spot volcanoes near spreading centres provides a measure of the depth of mantle convection cells.

It has been argued that frictional heating along slip zones between subducting and overriding plates provides the heat for partial melting[1,2]. At hot spots the suggested sources of heat are more controversial, ranging from shear heating in the asthenosphere[3] to more vague sources associated with deep thermal plumes originating at the core–mantle interface[4]. The depth of partial melting under volcanoes along slip zones is 100 ± 20 km, estimated[5] from considerations of the distance of volcano chains behind trenches and the seismically determined dip angles of the subducting plate.

There is a break in the distribution of separations between trench volcanoes at separations of $\sim$ 100 km, and we suggest that this indicates the depth of partial melting beneath these volcanoes. For each volcano along the various trenches we have calculated the separation, S, from its nearest neighbours[6–10]. The cumulative distribution of the number of volcanoes with nearest neighbours within a distance S is plotted against separation (Fig. 1) for volcanoes along major trenches and for the sum of these volcanoes. These distributions all rise rather uniformly up to separations of about 100 km and then flatten, indicating that there are relatively few trench volcanoes with nearest neighbours more than 100 km away.

Assuming that the region of partial melting is a belt along the slip zone at a depth of $\sim$ 100 km and that all along this belt the magma migrates upwards along random paths to the surface to form volcanoes, it is reasonable to suggest that the separation between the volcanoes would not generally exceed the depth of the magma source.

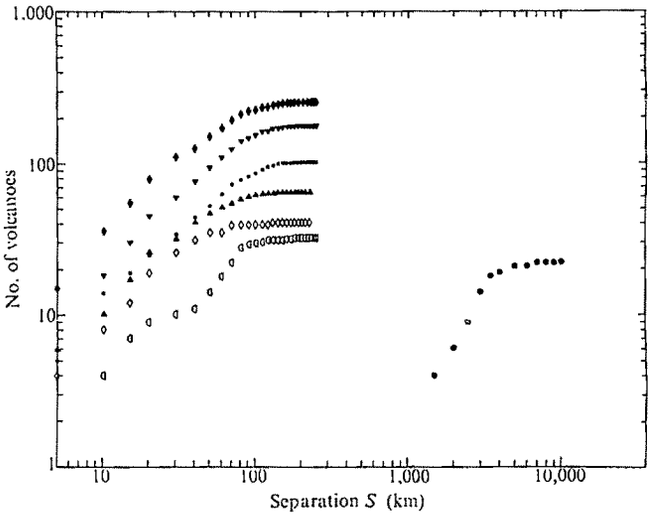

Fig. 1 The cumulative distribution of separation distances for trench and hot spot volcanoes, that is, the number of volcanoes separated from their nearest neighbours by less than S. Solid diamonds and solid inverted triangles are the sums of all trench distributions (from the International Association of Volcanology and ref. 10, respectively); solid circles, Indonesia[8]; solid upright triangles, Kamchatka-Kuriles[6,9]; open diamonds, central America[10]; open semicircles, Aleutians[10]; solid circles, hot spots[4].

Considering hot spot volcanoes located essentially along the oceanic ridge system[4,11], we have found that the distribution of separations between each hot spot volcano and its nearest neighbour shows a similar break or flattening (Fig. 1), but at a separation of $\sim$ 3,000 km, indicating that most hot spots have nearest neighbours within 3,000 km. This distance is the same as the depth to the core–mantle boundary, where deep thermal plumes may originate[4].

We propose that the lateral dimensions of mantle convection cells are also represented by the hot spot separations, rather than by ridge–trench distances[12,13], and that the break in the distribution of hot spot separations at 3,000 km is evidence for both whole mantle convection and a deep thermal plume origin of hot spots. We do not suggest that the magma extruded from hot spot volcanoes comes from the core–mantle boundary. The magma source is at the top of the convective plume just under the oceanic plate, and is consistent with a break at < 100 km in the distribution of separation distances[16] between the volcanoes which make up the Hawaiian chain of islands and guyots.

Massive sulphides and plate tectonics

SEVERAL authors have considered the genesis of various ores in terms of plate tectonic theory[1–6]. Most have discussed various possibilities for the origin of the ore solutions of massive sulphides and, with the exception of Guild[6], have stated or implied a fairly close genetic relationship between ore deposition and the processes of seafloor spreading and subduction. The nature of this relationship is, however, by no means clear and I suggest here that it may be very tenuous.

The deposits included in the term 'massive sulphide' are stratiform and wholly or largely composed of sulphides of iron with varying proportions of the sulphides of copper, lead and zinc, and minor gold and silver. Stratiform, massive oxide deposits (largely magnetite and/or haematite) are related ore types. The term includes 'volcanogenic massive sulphides'[7], but as used here it also covers very similar ores in sedimentary or sedimentary/volcanic successions (for example, Sullivan, Rammelsberg, Cobar, and Mount Isa).

Many geologists have discussed the possibility that massive sulphide deposits may be derived from heated seawater, or from meteoric water that has become an ore solution because of a hot water–rock interaction below the surface[8–11]. The principal requirements of this model are: a thermal anomaly sustained for sufficient time to precipitate an ore deposit; a system allowing long term downward penetration of water (probably to depths of several kilometres) and then upwards to the surface through major fractures; the presence of a suitable depositional site, which is commonly on the sea floor[7,12].

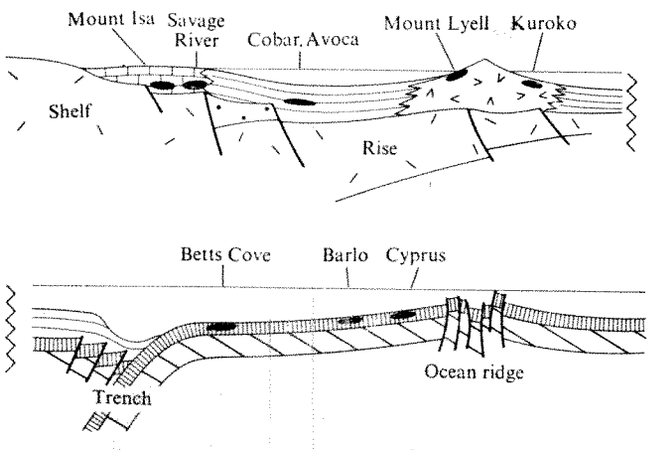

Fig. 1 Diagrammatic cross section of a continental margin to illustrate the range of tectonic environments of massive sulphides.

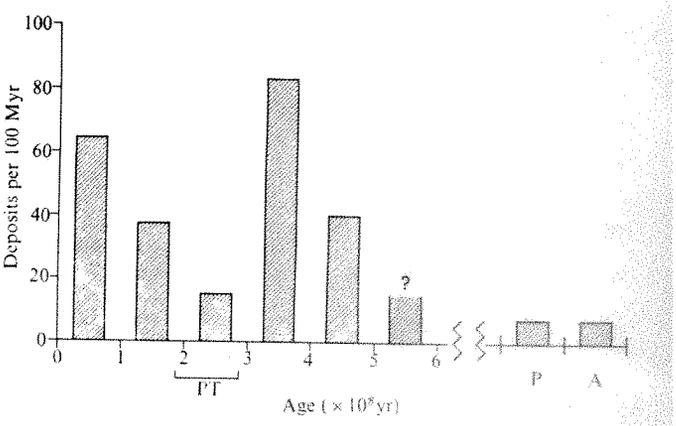

Fig. 2 Variation in the number of massive sulphide deposits per 100 Myr throughout the geological column. The Proterozoic (P) and Archaean (A) are each assumed to be 1,500 Myr long. PT, Permo-Triassic.

This geothermal model seems to account for the salient features of massive sulphides.

The principal host rocks to massive sulphides are volcanics of varying composition (mainly calc-alkaline), but some deposits occur in thick sediments (mainly shales and greywackes) with little or no evidence of volcanism (for example, Meggen,

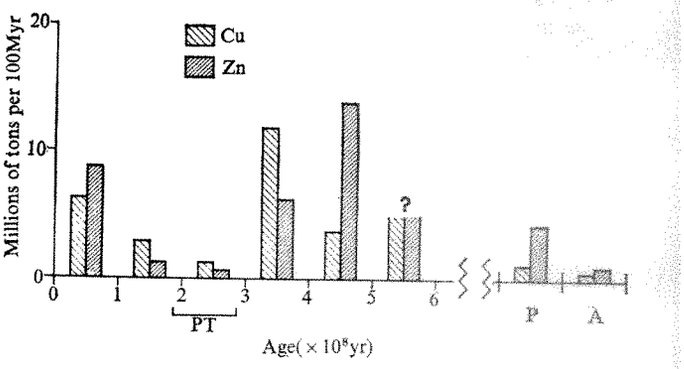

Fig. 3 Variation in the tonnages per 100 Myr of copper and zinc in massive sulphides through the geological column. The tonnages include production and reserves and are very approximate. A, Archaean; P, Proterozoic; PT, Permo-Triassic.

Rammelsberg, Cobar). There seems to be no evidence to support the statement[13] that massive sulphides are associated with mainly mafic volcanics. Deposits in volcanic successions do not show any correlation between the ore type (in terms of the Cu:Pb:Zn ratios) and the nature of the host rocks[14]. This seems to be true for all massive sulphides, except that where the host rocks are dominantly or entirely basaltic (as in Cyprus) the lead content is very low. If ore solutions derive their metal content through water–rock interactions several kilometres below the site of deposition, then correlations involving rock walls will be of little value. But a comparison between ore compositions and the nature of the rock successions for several kilometres below the deposits also showed no correlation, although the quality of the available data was poor. Copper and zinc are relatively abundant in most igneous and sedimentary rocks and the low degree of correlation between rock type and ore type is reflected in the geothermal model. Wide variations in the Cu:Zn ratio may be brought about by chemical factors during transport and at the site of deposition. Also predictable is the absence of lead ores in thick sequences of basic rocks, as these contain only a few parts per million (p.p.m.) of that metal. Another important feature of the host rocks is the lack of coeval plutons.

Massive sulphides tend to occur at distinct stratigraphic

horizons[7,14] which may be unconformities (Mount Lyell), sediment lenses within volcanics (Rosebery, Captains Flat), tops of volcanic sequences (Rio Tinto, Cyprus), or at changes in the composition of volcanics (Noranda area) or the nature of the volcanism (dacite domes of northern Honshu). Thus, the timing of ore deposition does not, apparently, relate to any clearly recognisable, unique event but to periods of hydrothermal activity brought about by various agencies such as faulting, pauses in volcanism, and so on.

Phanerozoic massive sulphides occur in a wide variety of tectonic environments[15], particularly in environments associated with orogenic belts (Fig. 1). Most occur in calc-alkaline island arcs and Andean-type volcanic belts (Mount Morgan, Rosebery, Mount Lyell, Rio Tinto, Hopa-Murgul, Shakanai), but some occur in the flysch and shelf sequences of the continental margin (Cobar, Avoca?), or in oceanic crust in ridge and ocean floor environments (Betts Cove, Skouriotissa, Besshi?). In the Palaeozoic of south-eastern Australia most massive sulphides occur in Andean-type volcanics, and formed fairly late in the development of the volcanic belts during the 'paratectonic' phases of the main tectonic cycles[16], when the volcanics were undergoing faulting, folding and granitic intrusion. Massive sulphides commonly occur in groups aligned along major features that provide deep seated plumbing systems.

Sulphide–sulphur in massive sulphides is enriched in ^{34}S relative to the meteoritic standard and generally shows only small variations within deposits. The values for some deposits may reflect mixing and re-equilibration between sulphur in magmatic water rising from depth and sulphate in seawater[17,18]. The same results can be achieved by mixing sulphur derived from the leaching of rocks with sulphate-bearing seawater in geothermal conditions.

Unlike several ore-types associated, and apparently genetically linked, with plutonic rocks (for example, tin–wolfram veins, nickel sulphide deposits and porphyry coppers), massive sulphides are well represented throughout the geological column (Fig. 2). Figure 2 is not very reliable because there are little adequate data from many areas, particularly from the Cambrian. The main features include the high number of deposits in the Carboniferous and Devonian, and the low number in the Permo-Triassic and the Archaean. The Carboniferous high reflects the large number of deposits in the Iberian pyrite belt, and the low value for the Precambrian (and the Cambrian?) may well be a function of the low preservation rate of these rocks[19]. The plot of tonnages (production plus reserves) of zinc and copper every 100 Myr (Fig. 3), though based on limited data, seems to confirm the Archaean and Permo-Triassic lows, and indicates the existence of several very large Proterozoic deposits (Sullivan, McArthur River, Mount Isa).

The principal features of massive sulphides do not conflict with, and are to some extent predicted by, the geothermal model outlined. In particular the model accounts for the lack of related plutons, the poor correlation between host rock and ore type, and the wide range of tectonic environments in which the deposits occur. The grouping along faults and the S-isotope data and overall chemical composition, are also compatible with the model.

If massive sulphides are essentially of superficial origin, with the entire ore forming process extending no more than a few km below the surface, it is difficult to see why there should be any close relationship with plate tectonic processes and related magmatism. The tendency for ore to be concentrated in marine volcanic zones in orogenic belts may simply be because such areas are the most favourable for developing convective hydrothermal systems and providing plumbing systems and depositional sites. The Permo-Triassic low in the distribution graphs may reflect the relatively low output of volcanic rocks at this time[20], and the large size of the few Proterozoic deposits may be a function of relatively stable conditions in large basins. Though the model seems to account for most of the data it does not necessarily explain the genesis of every deposit. The model needs to be tested on individual cases, possibly using isotope tracers[21].

Late glacial site in the central Grampian Highlands

The last British ice sheet probably reached its greatest extent 17,000–18,000 radiocarbon yr ago, when it covered much of the British Isles. We suggest here that this ice mass had disappeared 5,000 yr later. Significant new evidence comes from Loch Etteridge in the heart of the Grampian Highlands of Scotland (Fig. 1).

Loch Etteridge (grid ref. NN688929) lies in a deep kettle hole bordered by eskers and kame terraces at an altitude of 300 m, in upper Strathspey. The deepest accessible part of the kettle infill was sampled using a piston corer with a chamber 50 cm long and 5 cm in diameter. Seven metres of peat and gyttja overlie a typical late glacial sequence comprising organic deposits between minerogenic deposits (Fig. 2). Pollen analyses of the late glacial and basal postglacial deposits were carried out at 2.5-cm intervals. Samples for radiocarbon dating were obtained by combining material from four bores put down at the corners of a 30-cm square. This was possible because of the well defined stratigraphy, and was facilitated because the full sequence (Fig. 2) was obtained in a single chamber in each bore.

A date of 9,405 ± 260 yr BP (SRR-301) was obtained for the basal 4 cm of the postglacial organic deposits. The pollen spectrum is dominated by *Artemisia*, which exceeds 30% of the total land pollen, whereas values for woody taxa are less than 10%. Immediately above the dated sample, open habitat taxa decline markedly and pollen of woody plants increases. The radiocarbon date is much later than the date of approximately 10,300 yr BP which is conventionally assigned to the end of the Loch Lomond Stadial. In

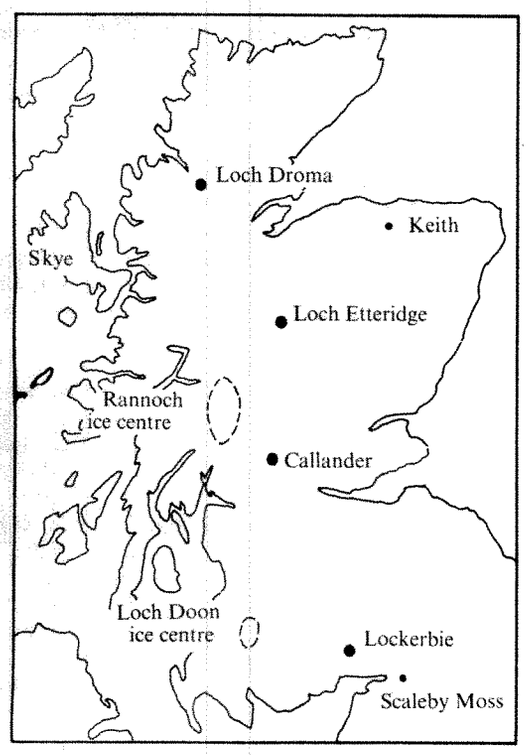

Fig. 1 Locations referred to in the text.

Skye, however, the cessation of minerogenic deposition varies considerably in different lochs, and the youngest date relating to this event is 9,420 ± 150 yr BP (ref. 1). Protracted minerogenic deposition at Loch Etteridge may be related to its altitude and to its location 8 km from the margin of a plateau ice cap which covered nearly 300 km², and which is considered to have developed during the Loch Lomond Readvance[2].

At the top of the Late Glacial interstadial deposits the pollen spectrum is characterised by woody plants, especially *Empetrum* and *Betula* c.f. *nana*, but *Artemisia*, Saxifragaceae and *Rumex* are also significant. In the overlying clay, pollen of woody plants declines and that of open habitat taxa increases. The top 1.5 cm of the interstadial deposits gave a date of 10,764 ± 120 yr BP (SRR-302). This accords with the value of 10,800 yr BP generally accepted for the beginning of the Loch Lomond Stadial, indicated, for example, by dates from Keith in Banffshire and from Scaleby Moss in northern England[3]. It has been inferred that at about 10,800 yr BP minerogenic deposition (implying solifluction on surrounding slopes) began at sites in Skye[1]. It therefore seems that at this time temperatures fell, probably rapidly, over a large area. It does not follow, however, that the glaciers involved in the Loch Lomond Readvance began to build up at this time.

Studies of Coleoptera at sites in England, Wales and the Isle of Man, suggest that a fall of temperature began before 12,000 yr BP and continued until the end of the Late Glacial interstadial[4], by which time mean July temperatures were probably 4°–5° C below present values. The interstadial climate may have been moderately continental, with winter temperatures depressed even more below present values[4]. For glaciers to develop on Ben Nevis a fall of more than 2° C in the present mean summer temperature is required[5]. Combining these figures it seems that the Loch Lomond Readvance began before, perhaps well before 10,800 yr BP. It can also be inferred, in view of the varied relief of Scotland and the marked gradients of former snow lines, that glaciers began to develop at different times in different places.

At the base of the more organic interstadial deposits, the pollen spectrum is dominated by *Empetrum* (over 45%), but *Betula* c.f. *nana* and *Juniperus* are also significant. A sample 1.5 cm thick yielded a radiocarbon date of 11,290 ± 165 yr BP (SRR-303).

The pollen spectrum at the base of the organic deposits is characterised by high values of *Rumex* (over 20% of total land pollen) with *Salix* (many of which resemble *Salix c.f. herbacea*) and Saxifragaceae also important. Values for woody plants increase progressively towards the upper part of the dated horizon.

The basal organic deposits gave a radiocarbon date of 13,151 ± 390 yr BP (SRR-304). The most likely source of any error is the hard water effect, which can give apparent ages that are almost 3,000 yr too great, although the error is rarely as large as this[6,7]. Limestone does not crop out in the area draining to Loch Etteridge, however, and glacial erratics of limestone have not been found. No shells were found in the lake deposits. The possibility cannot be excluded, however, that inert carbon from the complex metamorphic rocks of the surrounding area was incorporated in the dated bulk sample. On the other hand, the date of 10,764 ± 120 yr BP from similar (though organically richer) material higher in the sequence agrees with expectations, and there can be no hard water error here.

Because a thickness of 3–4 cm of the deposits was used for dating, the date obtained, if valid, is younger than the age of the very bottom of the organic layer. It is particularly significant that the site is a deep kettle hole, in which dead ice may have remained for hundreds (or even thousands) of years after deglaciation of the surrounding area[8]. Thus the basal date, if valid, is a minimum date of deglaciation.

The Loch Etteridge date is not unique in Scotland. Wood from lake deposits near Lockerbie in Dumfriesshire has

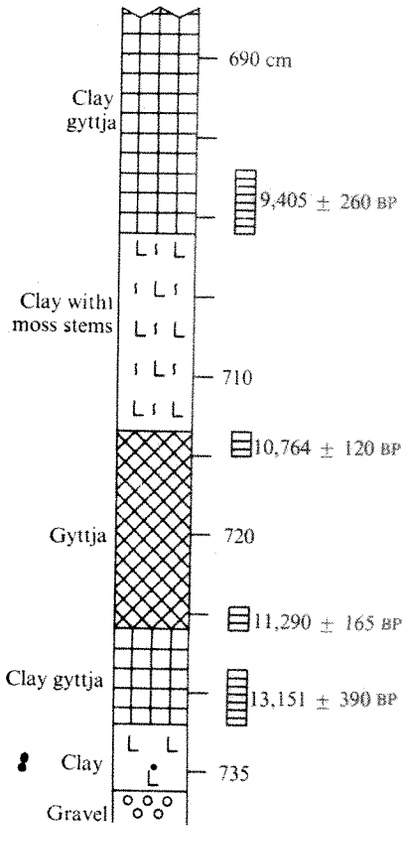

Fig. 2 Stratigraphy and radiocarbon dates at Loch Etteridge.

been dated at 12,940±250 yr BP (ref. 9). Lockerbie is only 60 km from the major centre of icesheet accumulation in the Southern Uplands (Loch Doon Basin). In the heart of the mountains of NW Scotland a date of 12,810±155 yr BP has been obtained for deposits from Loch Droma[10]. Near Callander the basal organic deposits in a kettle hole have provided a date of 12,750±120 yr BP. This site is only 45 km from the centre of the area of greatest ice sheet accumulation in the British Isles (around the Rannoch basin). The Loch Etteridge basal date adds significantly to this evidence, because the site is in the middle of the Grampian Highlands.

Together, the four dates (all of which, if valid, are minimum dates of deglaciation) show that by about 13,000 yr BP the last ice sheet had disappeared from most of Scotland. At about this time two significant, probably interrelated, events are reported to have occurred. Coleoptera and radiocarbon dates from a site in North Wales, indicate that at about 13,000 yr BP temperatures rose very rapidly, with summer temperatures becoming at least as warm as those of the present day[11]. Seafloor sediments indicate that deglacial warming of the North Atlantic Ocean adjacent to the British Isles occurred at about 13,500 yr BP, polar waters having retreated far to the west by 13,000 yr BP (ref. 12). In view of these profound changes we find it difficult to believe that any remnants of the British ice sheets which may have remained at about 13,000 yr BP could have survived for much longer. Total deglaciation by 12,500 yr BP seems a conservative suggestion.

The last British ice sheet, which probably reached its greatest extent at about 17,000–18,000 yr BP, had therefore wasted away by 12,500 yr BP at the latest. Subsequently, glaciers built up again in many mountain areas, and were especially extensive in the Scottish Highlands[13] where they began to accumulate before the climatic deterioration which occurred at about 10,800 yr BP. The glaciers probably reached their maximum extent about 10,300 yr BP, but it is not yet known how long they took to decay. The fact that minerogenic deposition, which implies solifluction and sparse vegetation, continued locally till approximately 9,400 yr BP may be significant in this context.

This research was financed by the Natural Environment Research Council. We thank Dr D. D. Harkness for the radiocarbon dating.

Late Pleistocene American obsidian tools

We have dated some of the oldest examples of obsidian use yet known in America. The obsidian originates from a new location, the Mostin site, which contains about a dozen burials and is located near the Borax Lake site in northern California. There it is thought that man lived as long ago as 10,000 yr and perhaps even at the end of the Pleistocene[1].

During test excavations in the summer of 1973 human bones and obsidian artefacts[2,3] were found at the new Mostin site (SDA-66), located 16 km north-west of the Borax Lake site. The Mostin site (39°N; 122°50′W) is situated along Kelsey Creek about 2.5 km south of Clear Lake and 5 km from the nearest obsidian source south at Mt Konocti[4-6] (Fig. 1). The Mostin site is now being exposed by the erosive action of Kelsey Creek which is cutting into lake sediments 6 m high deposited during an earlier higher level stage of Clear Lake[7].

The samples sent to us for dating and for tracing their origin included the left fibula, left tibia and the diaphysis of the right femur of burial 4 and seven associated obsidian artefacts. The bone samples were combined and dated by the radiocarbon content of their collagen fraction according to established procedures[8] and yielded a date (UCLA-1795A) of 10,260 ± 340 yr (ref. 9). The statistical error encompasses any deviation due to correction for isotopic fractionation of $^{13}C/^{12}C$ in case the resident human population had been heavily dependent on freshwater fish.

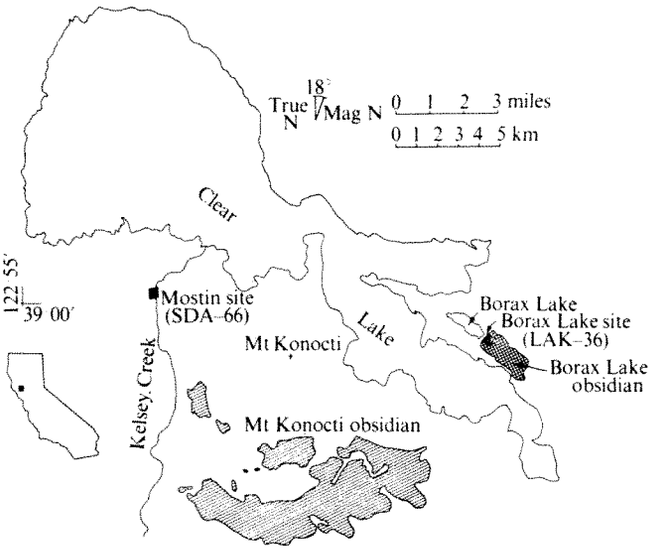

Fig. 1 Location of obsidian sources and archaeological sites, near Clear Lake, California.

The obsidian artefacts were classified into a functional typology based on their morphology and microscopic wear patterns (Table 1). Artefacts M3 (burin) and M6 (scraper) were used as tools, whereas M1 was a biface blank and M4, 5 and 7 primary decortication flakes removed from nodular cobbles of obsidian. Artefacts M1 and 6 showed fractures indicative of percussion flaking with a soft instrument from a prepared core. M2 has the appearance of a blade but its precise classification is uncertain.

All obsidian pieces were subjected to hydration rim thickness measurements and source characterisation by neutron activation and X-ray fluorescence analysis. From the differences in hydration values it became apparent that probably two types of obsidian had been utilised. Artefacts M1, 3 and 6 show a clustering of hydration rind values between 6.2 and 6.8 μm, whereas M4, 5 and 7 are all 4.6 μm. The appearance of artefacts 1, 3 and 6, and 4, 5 and 7 are the same respectively within each group, whereas both groups are distinctly different in visual appearance.

Table 1 Functional typology of obsidian artefacts

Artefact sample no.	UCLA obsidian hydration no.	Hydration measurement (μm)	Origin by X-ray fluorescence*	Functional typology	Notes
M1	3754	6.4	Borax Lake	Biface blank	Partially finished preform
M2	3755	5.7/12.6	Borax Lake	Blade	Unretouched irregular blade with a single medial ridge and convergent edges
M3	3756	6.2	Borax Lake	Thick flake burin	Appearance (and probable function) of an oblique truncation burin—a European Palaeolithic form
M4	3757	4.6	Mt Konocti	Primary decortication flake	Broken from M7, no retouch
M5	3758	4.6	Mt Konocti	Primary decortication flake	No retouch
M6	3759	6.8	Borax Lake	Flake scraper	Three edges exhibit even, regular wear pattern of small scalar flakes
M7	3760	4.6	Mt Konocti	Primary decortication flake	Broken from M4, no retouch

* Source discrimination based on results of a ternary diagram of the intensity of the elements zirconium, rubidium and strontium.

Neutron activation analysis was too indistinct in this case to separate two suspected sources of obsidian, Mt Konocti and Borax Lake, but additional X-ray fluorescence measurements revealed by comparison with known source materials that the slower hydrating obsidian originated from Mt Konocti and the faster from the Borax Lake area.

Comparison of hydration and source data with a hydration rate curve for Borax Lake over a time span of the past 4,000 yr suggests that the rate over the entire 10,000 yr available now is at least partially exponential in nature (unpublished work of F. J. Findlow, S. P. De Atley, and J. E. Ericson). Moreover, this work shows that some two dozen obsidian artefacts found at Borax Lake may be much older than had been anticipated.

The Borax Lake assemblage also contains obsidian originating from Mt Konocti about 5 km away. The reason for this exploitation may lie in the fact that obsidians from the two sources differ in hardness: Mt Konocti material has a hardness of 500 to 600 kg mm^{-1} whereas that from Borax Lake is 734 ± 12 kg mm^{-1}.

This work suggests that obsidian was used in Northern California at least as early as the interface of the Late Pleistocene/Holocene and the extent of early settlement may indeed have been much more extensive than hitherto thought.

We thank R. King, California State College, Sonoma for sample materials, J. T. Wasson for permission to use the neutron activation equipment at University of California, Los Angeles, J. L. Bischoff for X-ray fluorescence instruments at USC, and V. Bennett for hydration rim and C. A. Singer for functional analysis, at UCLA. This study was supported by the National Science Foundation.

BIOLOGICAL SCIENCES

Particle containing uncleaved major head protein (P23) which is maturable into the head of phage T4

PREVIOUS results[1] suggested that τ-particles produced by a phage T4 temperature-sensitive (*ts*) mutant in gene 24 can be matured into T4 phage heads after a shift to a permissive temperature (temperature shift-down). The experimental evidence which supports this hypothesis can be summarised as follows: (1) the number of τ-particles per bacterium observed after temperature shift-down of a 24^- infected culture decreases concomitantly with an increase in the number of normal T4 phage particles; (2) preshift (under nonpermissive conditions) 24^- radioactively pulse-labelled cultures produce radioactively labelled normal phage after temperature shift-down; (3) after temperature shift-down, preshift radioactively labelled major head protein P23 (molecular weight 59,000) is cleaved into P23* (molecular weight 47,500) both molecular weights determined by A. Tsugita from the amino acid composition, (personal communication)[2-5].

But we also know that τ-particles produced in 21^- infected bacteria cannot be further matured after temperature shift-down, although they are morphologically identical to those produced in 24^- infected cultures[1,6].

Here we shall demonstrate that the uncleaved P23 is organised in the form of a precursor particle, in which the later conversion of P23 to P23* is conservative. Our complete set of experiments will be published elsewhere[16]. With the previous observations, these new results provide very strong evidence that 24^-–τ-particles are maturable into phage heads.

Our previous results[1] did not rule out the possibility that the phage capsids observed after temperature shift-down are built from subunits drawn from a pool containing subunits built before as well as after shift. (In the following we shall distinguish them as 'preshift subunits' and 'postshift subunits'.) An important part of preshift subunits could stem from the breakdown of τ-particles (see discussion in ref. 1). If capsids of phages made after shift were composed of a mixture of preshift and postshift subunits, then a dispersive mode of transfer would have taken place. The transfer would be conservative when the preshift subunits already formed a particle which, after shift, was transformed as a whole into a capsid. We shall demonstrate (Figs 1 and 2) a true conservative transformation of a P23-capsid into a P23*-capsid, by density labelling the preshift subunits as 'heavy' and the postshift subunits as 'light'. By supplementary radioisotope pulse labelling the fate of both types of subunits can be followed independently.

We used T4.10(amB255).24(tsL90). The tail-less heads of mutants in gene 10 have the advantage of being easily emptied by DNase treatment[7]. This allowed us to analyse the density of emptied heads without having to take into account the full DNA complement of a phage head and the density variability due to mixing of preshift and postshift phage tails. After a partial purification by sucrose gradient velocity sedimentation, the emptied heads were looked at in the electron microscope, their protein composition was analysed by SDS-polyacrylamide gel electrophoresis[2,8] and their density was measured by CsCl gradient centrifugation.

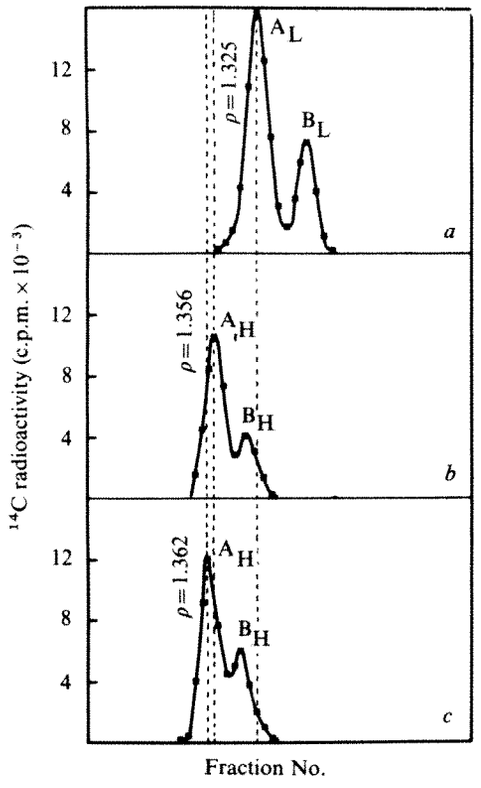

Fig. 1 Density distribution of phage heads treated with DNase obtained in heavy medium alone, after transfer from heavy into light medium and in light medium alone. DNase treated phage heads were purified by a sucrose gradient of which the 300S fractions containing emptied head were collected. These fractions were then analysed by density equilibrium centrifugation. *a*, Emptied heads obtained from 10⁻ infected cells grown in normal light medium; *b*, emptied heads obtained from 10⁻.24⁻ infected cells at 30 min after the culture was shifted from completely heavy medium at 40.5° C into normal light medium at 30° C (permissive temperature); *c*, emptied heads obtained from 10⁻ infected cells grown in completely heavy medium. The explanation for the existence of two peaks is discussed in Fig. 2. Peaks A and B refer to partially emptied and completely emptied heads respectively. The subscripts L and H refer to light and heavy medium.

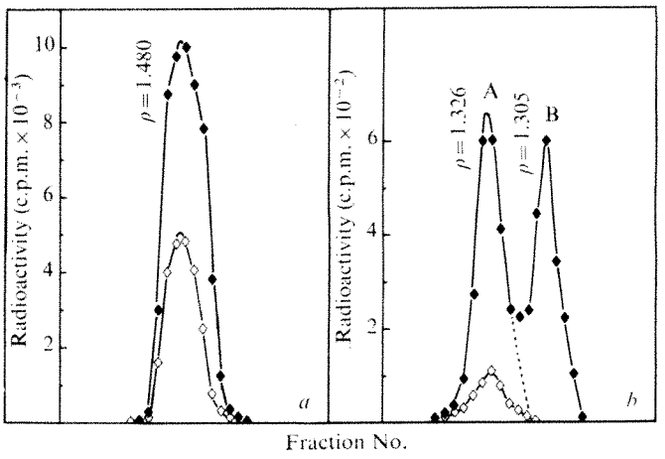

Fig. 2 DNA content of 10⁻ DNase-treated phage heads compared with the DNA content of wild-type phage. Cultures of *Escherichia coli* B^E and *Escherichia coli* CR63 were infected with T4.10 (am B255). At 16 min after infection 16 μCi ml^{-1} of ^{32}P and 200 μCi ml^{-1} of ^{3}H-amino acids were added. At 90 min the bacteria were lysed with chloroform in the presence of DNase. The lysates were centrifuged on a 15–40% sucrose gradient for 45 min at 30,000 r.p.m. in an IEC SB 405 rotor. The 1100S peak (phage *a*) and the 300S peak (emptied heads *b*) were then layered on CsCl with density ρ = 1.48 and ρ = 1.32 (phage and emptied heads respectively). Radioactivity distribution of ^{3}H-labelled proteins (◆ ◆ ◆) and ^{32}P-labelled DNA (◊ ◊ ◊). Labelling conditions for phage and emptied heads were identical.

The density profile for emptied heads obtained with 10⁻ infected cells in light medium is shown in Fig. 1*a*, and that of 10⁻ emptied heads in heavy medium in Fig. 1*c*. In both cases there are two peaks A and B which differ in density by 0.021 g ml^{-1}. The two peaks occur normally and are due to two types of emptied heads: those which are completely emptied (peak B_L; density = 1.304 g ml^{-1}) and those still containing about 20% of DNA (peak A_L; density = 1.325 g ml^{-1}). The incomplete removal of DNA from all of the DNase-treated 10⁻ heads has been observed by Hosoda and collaborators (personal communication). We have repeated an experiment to demonstrate the presence and absence respectively of DNA in the denser and less dense types of emptied heads. The results of this experiment are shown in Fig. 2. Clearly, peak A contains DNA while peak B does not. Although both types of emptied head were nearly always found after DNase treatment, their relative amounts varied with every experiment.

From Fig. 1 we deduce that the two emptied head peaks A and B (double peak) are shifted by 0.037 g ml^{-1} when grown in heavy medium (compare peaks A_L and A_H). The density profile of Fig. 1*b* was obtained from emptied heads which arose after temperature shift-down and simultaneous transfer to light medium with the double mutant 24(tsL90).10(amB255). This double peak is 0.031 g ml^{-1} denser than the light one. This result is incompatible with a dispersive mode of transfer and suggests instead that the transfer is conservative.

It is, however, possible that the infected bacteria do not immediately synthesise structural components after shift into light medium. This would mean that preshift built subunits cannot mix with postshift newly synthesised light subunits. To test this possibility we labelled preshift built material with ^{14}C-labelled amino acids and postshift built material with ^{3}H-labelled amino acids. These results shown in Fig. 3 demonstrate that light subunits are synthesised immediately after temperature shift and that most of the ^{14}C-preshift labelled emptied heads remain in a peak which is considerably denser than the ^{3}H-labelled emptied heads. Furthermore, the ^{14}C-labelled emptied heads remain from 15 to 60 min after temperature shift.

Our previous results together with these experiments give good evidence that 24⁻–τ-particles can be transformed into phage heads in a conservative mode. We have, however, no proof that this τ-particle is also a precursor in the normal pathway of phage head maturation as proposed by Simon[9]. Among the P23-containing particles, only the 24⁻–τ-particle can be further matured; 21⁻–τ-particles, which are morphologically indistinguishable, cannot be transformed[1,6,10]. The same is true for the so-called "crummy heads"[11] produced by *ts* mutants in gene 23[16]. Laemmli and Favre[12] have shown that in pulse-chase experiments in wild type a precursor particle called prohead I which contains predominantly uncleaved P23 and possibly P22 and IP III can be converted into a particle called prohead II, which contains essentially P23*, P22 and IP III. Other results[6,10] show that the 21⁻–τ-particles and the prohead I particles have similar properties (S value, protein composition). These results suggest that the 24⁻–τ-particles may be a true precursor in the normal pathway of phage head maturation.

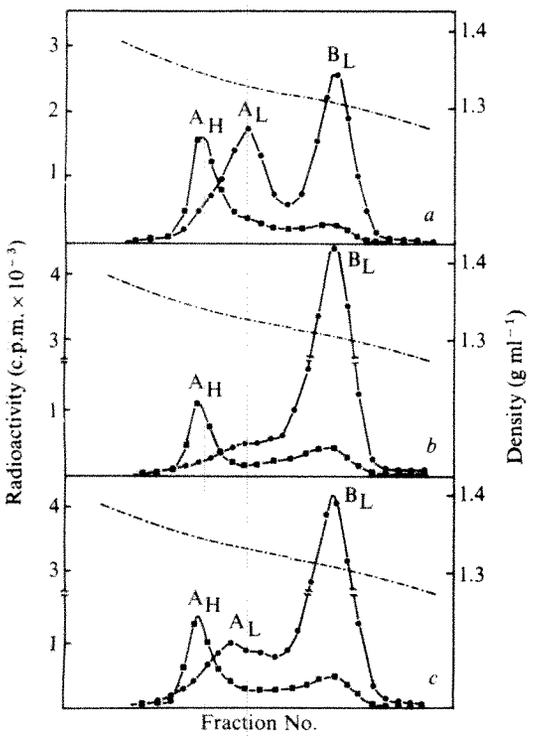

Fig. 3 Density distribution of pre- and postshift labelled emptied heads of 10⁻.24⁻ infected cells at different times after temperature shift-down. *a*, Density distributions of preshift ^{14}C-labelled empty heads (■ - ■ - ■) and postshift ^{3}H-labelled empty heads (● - ● - ●) of a sample taken 15 min after temperature shift-down; *b*, *c*, similar density distributions but of samples taken 30 and 60 min after temperature shift-down respectively. Peaks A_L and B_L refer to partially emptied and completely emptied light heads. Peak A_H refers to partially emptied heavy heads.

Assuming that these precursor particles containing P23 undergo cleavage *in situ* (that is, without breaking down and reassembling in a compartmentalised space), then the number of P23 subunits must remain identical throughout the transformation. This is highly interesting, since the overall size of the phage head is about 20% larger than that of a τ-particle[13]. In this context, it is interesting to note that other results[17] of our laboratory indicate that the lattice constant of the capsids of giant phages[14] is different from that of polyheads. From previous considerations on polymorphism[15] it is likely that τ-particles have the same lattice as polyheads and similarly that the giants are not different from normal phage in this respect.

We thank Drs J. Hosoda and M. Showe for suggestions and reading the manuscript.

Banding and chromatid separation in Chinese hamster chromosomes

In general, a chromosome exhibiting its banding pattern does not permit any internal helix to be seen, and vice versa. During studies with chromosomes of Chinese hamster cells, cultivated *in vitro*, it was possible to correlate G banding and spiral structure with the spatial relation between sister chromatids. G banding of human chromosomes was first described by Sumner *et al.*[1] and later was demonstrated in the Chinese hamster chromosomes by Radabli and Kriukova[2]. By a hypotonic treatment, the spiralisation of the chromosomes was demonstrated by Ohnuki[3] in man and later by Kato and Yoshida[4] in the Chinese hamster.

Chinese hamster fibroblasts of the DON line were grown for 2–3 d in Puck's medium supplemented with 10% calf serum and 1% glutamine, collected by trypsinisation after 5.5 h of colchicine treatment (10 μg ml^{-1}), and then centrifuged at 1,000 r.p.m. for 10 min. The supernatant was replaced by a mixture of KCl (0.055 M), KSCN (0.062 M), $NaNO_3$ (0.055 M) and CH_3COONa (0.055 M) in the proportion 4:1:2:2, which is the hypotontic saline used by Ohnuki[3] to demonstrate spiralisation in chromosomes. Cells were then washed, fixed for 50 min with methanol and glacial acetic acid (3:1), spread on slides according to the method of Moorhead *et al.*[5], stained with 2% Giemsa R66 for 30 min, washed with tap water, dried at room temperature and mounted in DPX. Metaphase chromosomes were examined and some of them were photographed with a Zeiss × 100 Neofluar objective.

Table 1 The distribution of 106 metaphase figures

		Appearance of chromatids				
		Banded	Intermediate	Visible helix	Homogeneous	Total
Separation of sister chromatids	Separate	0	1	38	0	39
	Partly separate	0	26	1	4	31
	Closely apposed	36	0	0	0	36
	Total	36	27	39	4	106

They showed either banding, a spiral structure, an intermediate appearance, or homogeneity without evident internal structure; the first three are exemplified in Fig. 1. It is of interest that the banding pattern appeared on the chromosomes without postfixation treatment, which is usually used for banding, and was described by Sumner *et al.*[1]. Within any one cell, all chromosomes were of similar appearance. It was also noted whether sister chromatids were closely opposed to each other, or were separated. If they were separated, the outside width of the whole chromosome was about 2.4 μm, but only 0.8 μm if the chromatids were together. Thus, the apparent separation was due to movement apart and was not wholly explicable by loss of material between the chromatids. It is interesting to compare Darlington's correlation of internal change in chromosomes with their external mechanics[6], but he was concerned with the question of an internal split, whereas the results reported here relate to regional affinity for dyes. In some cells the chromatids were separated along only a part of their length. In each of 10 slides, at least 10 metaphase figures were examined and classified, the counts so obtained are presented in Table 1, which shows that closely paired chromatids always exhibited banding, and conversely, but that the internal helices became evident and the banding lost only when the chromatids separated.

A possible interpretation of this is that the manifestation of banding depends on chromosomal material which is also necessary for maintaining the close apposition of sister chromatids and which conceals the helix, but the disappearance of the bands in this experiment is nevertheless also attributable to the withdrawal of interchromatid fibres. (Fig. 1*b*). Kato and Yoshida[4] tried to correlate G bands with coils by comparing the number of bands with the number of coils on the homologous chromosomes of the Chinese hamster. This correlation was only based on the constancy of the number of the coils in each individual chromosome. But they could only show the resemblance of the knobs, which are the relics of bands on the spirals, and the bands. No correlation has been shown between bands and the spirals on the chromosomes of the Chinese hamster. Ford *et al.*[7], by using a modified whole-mount method, observed the spiral structure of human chromosomes distinctly, and found that the number of turns diminishes as mitosis proceeds. They concluded that the number of turns was not constant but varies with the preparation and doubted if the number of gyres would be of any value for the identification of the individual chromosomes, as was proposed by Ohnuki[3]. The diminution of the gyres in number, during mitosis, would necessitate the unwinding of the chromatids around their axis, which could lead to partial or complete disappearance of the bands. (Fig. 1*c*).

Virus-like particles induced in guinea pig cells by 5-bromo-2′-deoxyuridine are morphologically similar to murine B-type virus

VIRUS-LIKE particles in tissues of leukaemic and normal guinea pigs have been demonstrated repeatedly[1–5]. Tumour cells contain intracisternal particles resembling mouse intracisternal A particles[3], and extracellular virus-like particles are found in tissues of leukaemic guinea pigs. To the best of our knowledge, a convincing micrograph of a virus-like particle budding from the surface of a guinea pig tumour cell (*in vivo*) has never been published. In a separate study (J.E.D. and K.P., in preparation), it has been concluded that

the guinea pig leukaemia virus[1–3] results from the release of intracisternal A particles from dying tumour cells.

Recently, several groups have induced virus-like particles in tissue cultures of a wide variety of normal and neoplastic guinea pig cells using 5-bromo-2′-deoxyuridine (BrdU) (refs 6–9). Guinea pig cells treated with BrdU contain intracytoplasmic A particles[7,8] and produce extracellular virus-like particles of uncertain morphology. These extracellular particles are formed by a budding process, but it is difficult to determine from published micrographs whether these particles and buds are characteristic of C-type particles.

The categorisation of viruses found in mouse neoplasms as A, B, C, and D, first proposed by Bernhard[10], and later expanded to include two types of A particles[11], has recently been reviewed[12,13]. Intracisternal A particles bud from the rough endoplasmic reticulum into cisternae and seem to be unrelated to any other type of virus-like particles. Intracytoplasmic A particles, more homogeneous in size than intracisternal A particles, occur in the cytoplasmic matrix of the cell, and, in some cases, become the core of B particles. The intracytoplasmic A particles are not precursors of C-type particles. B particles are associated with mouse mammary tumours and can be distinguished from C-type particles by the morphology of the buds, the presence of relatively long spikes on negatively stained particles, and eccentric nucleoids in some of the mature particles. A-type particles are always intracellular, while B and C particles are extracellular.

Virus particles found in mice and other animals should be identified carefully because structural differences may represent important biochemical and genetic differences. In the case of the guinea pig, the virus-like particles induced by BrdU have alternatively been classified as C-type[6,7,9], or as guinea pig leukaemia virus-like[8]. In the study reported here, various cell lines, including tumour cells cultured from leukaemic strain 2 guinea pigs, normal guinea pig embryo cells derived from strain NIH, and 3-methylcholanthrene and benzo[a] pyrene-treated normal guinea pig embryo cells, have been examined for virus-like particles after induction for 5 d with 40 μg ml^{-1} of BrdU. Regardless of the source of the cells, virus particles with a morphology similar to that of the murine B-type virus, as well as intracytoplasmic A particles were the only types found. Although extracellular particles were observed frequently, budding particles were relatively rare (approximately one bud per fifty cell profiles). Figure 1 shows selected examples of thin sections of virus-like particles found in BrdU-treated guinea pig cells. Figure 1*a* shows an intracytoplasmic A particle; both electron dense shells are of approximately equal density. This is also true of the budding particles shown in Fig. 1*b* and *c*. At no time have budding particles been observed that failed to contain a completely formed nucleoid. Figure 1*f* and *g* illustrate eccentric nucleoids in particles occuring in a pellet of purified induced virus, while Fig. 1*h* shows the nucleoid of an immature particle in the same preparation. Because of the density of this pellet, osmium did not penetrate well, and the viral membranes were not well preserved. This had no effect on the nucleoids, which were adequately prefixed with glutaraldehyde. If Fig. 1*a* and *h* are compared, it can be seen that the intracytoplasmic A particle is identical to the nucleoid of a purified extracellular immature particle.

Figure 2 presents micrographs of negatively stained guinea pig particles induced by BrdU, and for comparison with Fig. 1, illustrations of several stages in the development of murine B and C particles. The presence of intracytoplasmic A particles, the ultrastructural characteristics of budding particles, and the presence of eccentric nucleoids in mature extracellular particles are criteria used to define murine type B particles. A further criterion is the presence of spikes in negatively stained particles. Although C-type particles also have spikes[14], they are short and difficult to visualise. The spikes present on the induced guinea pig particles and shown in Fig. 2*a* and *b*, most nearly resemble those found on B-type particles.

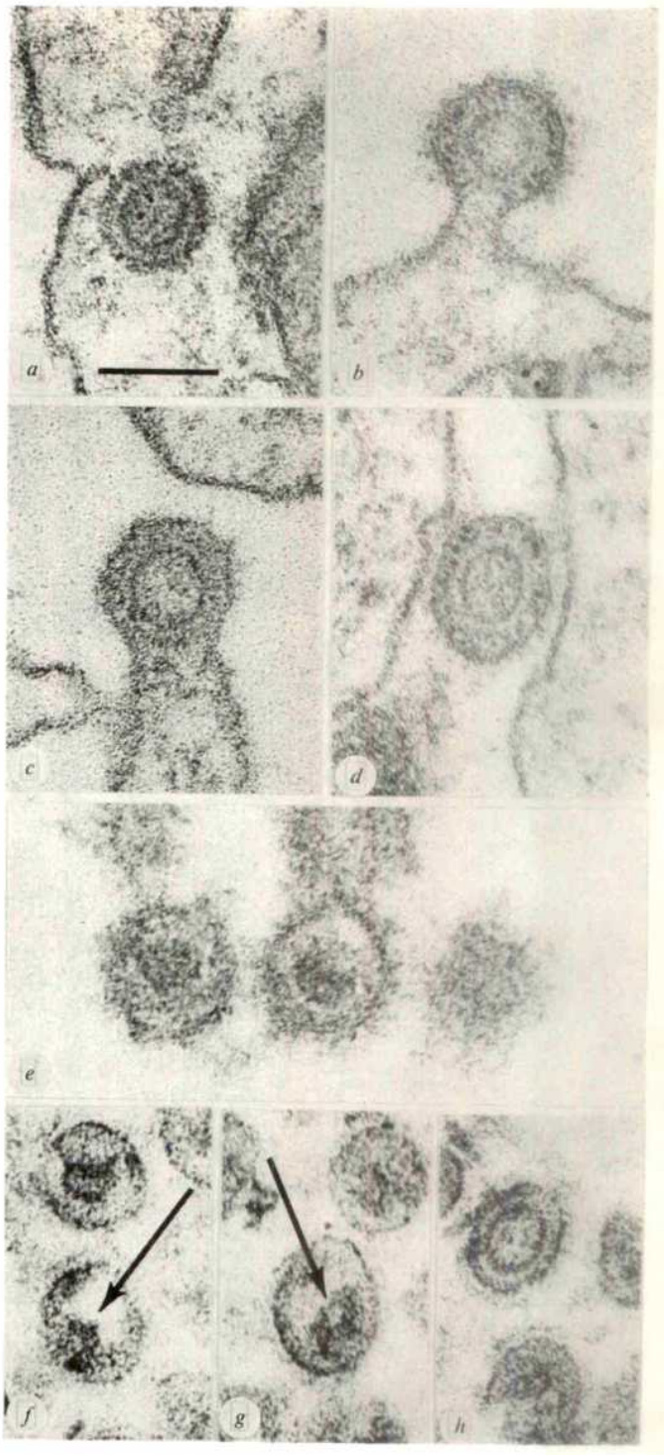

Fig. 1 Virus-like particles induced in guinea pig cells by BrdU. Samples were fixed *in situ* with 3% glutaraldehyde in Millonig's buffer, scraped and pelleted, and post-fixed with 1% osmium tetroxide in 0.1 M cacodylate buffer for 2 h. After dehydration in ethanol and propylene oxide, the pellets were embedded in Epon-Araldite. Thin sections were stained with uranyl acetate and lead citrate and examined at 80 kV in a Siemens 101 equipped with a 50 μm objective aperture. The bar represents 100 mm, and all figures are at the same magnification (approximately 160,000). *a*, Intracytoplasmic A particle; *b*, *c*, budding particles; *d*, an apparently extracellular immature particle; *e*, extracellular mature particles; *f*, *g*, particles occurring in pellets of purified induced virus. Note the eccentric nucleoids (arrows); *h*, nucleoid of immature particle in the same pellet shown in *f* and *g*.

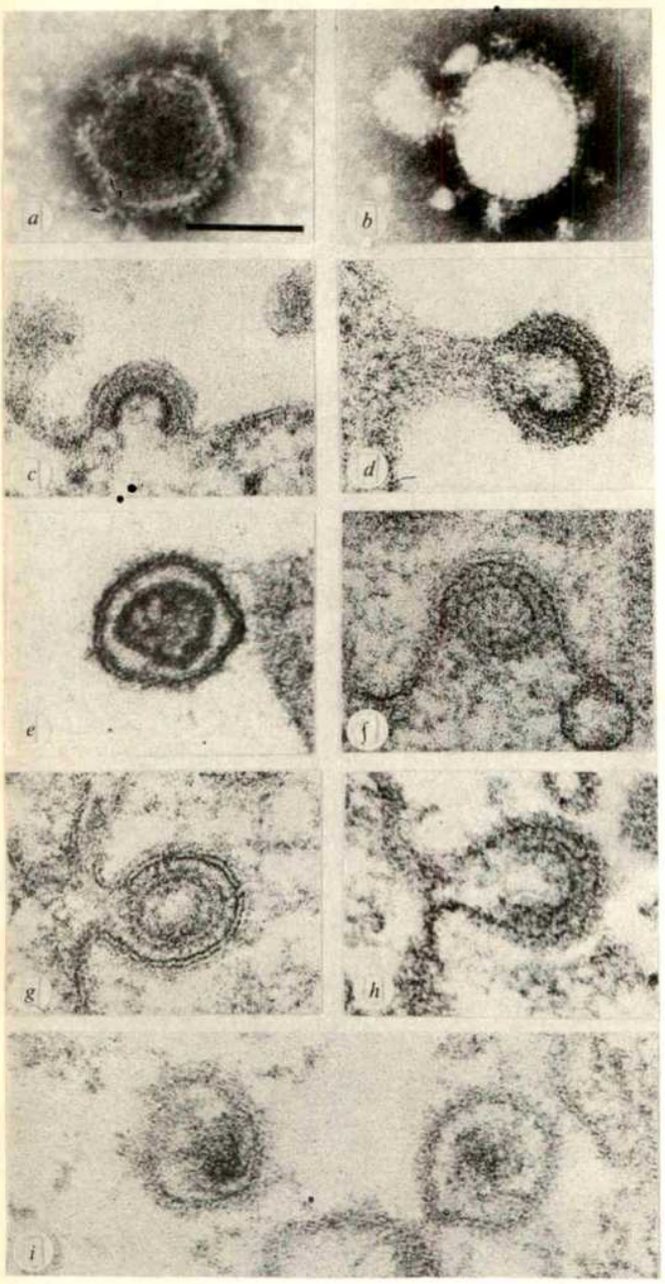

Fig. 2 *a*, *b*, BrdU-induced guinea pig particles, negatively stained with 0.5% neutral phosphotungstic acid following brief fixation with 3% glutaraldehyde; *c*, *d*, buds of murine C-type particles (*c*, Rauscher leukaemia virus in human embryo kidney cells; *d*, the C-type particle present in L cells); *e*, mature C-type particle (RLV in HEK cells); *f*, *g*, *h*, buds of mouse mammary tumour virus (B-type virus, in mammary tumour); *i*, mature murine B-type particles (in mammary tumour). The bar represents 100 nm; all figures are at the same magnification (approximately 160,000).

Figure 2*c* and *d* illustrate buds of murine C-type particles, and show how the inner layers form concomitantly with the bud. The electron density of the inner component is significantly greater than that of the intermediate layer. Figure 2*e* shows the centrally positioned nucleoid of a mature C-type particle. Buds of murine B-type particles may either contain preformed nucleoids (intracytoplasmic A particles; Fig. 2*f* and *g*) or the nucleoid may form in synchrony with the bud (Fig. 2*h*). In either case the electron densities of the inner component and the intermediate layer are approximately equal. This is essentially what is seen in the induced guinea pig particles, although buds form only by incorporating intracytoplasmic A particles. Thin sections of mature murine B-type particles may exhibit either eccentric or central nucleoids (Fig. 2*i*), although eccentric nucleoids usually predominate. In the induced guinea pig particles, eccentric nucleoids are less frequent, and are only very noticeable in older preparations, such as the purified pellet illustrated in Fig. 1*f* and *g*.

The particles induced in guinea pig cells resemble the murine B-type particle in several important ways. Although the induced guinea pig particles may not be morphologically identical to murine B-type particles, it is evident that they are not typical C-type particles, as has been reported[6,7,9].

There is a clear need for caution in categorising newly observed virus-like particles. Without high resolution micrographs of budding particles, it is extremely difficult to characterise accurately oncornavirus-like particles. Efforts are now under way to analyse biochemically particles and induced virus and the guinea pig leukaemia particles and to test their biological activities. If the preliminary diagnosis of this particle as a B-like virus is substantiated, the phenotype of a C-type virus genome has not yet been demonstrated in guinea pigs.

K. P. is a visiting scientist from the Hebrew University of Jerusalem.

Cancer, autoimmunity and IgA-deficiency related by a common antigen–antibody system

WORKERS[1-5] have reported IgG-precipitating antibodies against predominantly high molecular weight ruminant immunoglobulins to be present in the sera of certain patients with IgA deficiencies. The most frequently identified antigen is bovine IgM but we have also found a high frequency of precipitating antibodies to bovine associated mucoprotein (BAMP) (Table 1). Immunochemical studies have demonstrated that the antibodies to these two proteins are entirely distinct and that antibodies to BAMP in human sera can only precipitate with a fraction of the antigenic determinants detected by antisera raised in rabbits against BAMP.

Bovine associated mucoprotein is a constituent of the fat globule membrane which is formed by vesicular secretion from

the alveolar epithelial cells of the bovine mammary gland. Jackson *et al.*[6] determined a molecular weight of 123,000 for BAMP by analytical ultracentrifugation, although lyophilised and dissolved BAMP elutes in the void volume from Sephadex G-200. BAMP contains 25% carbohydrate of which one-fifth is sialic acid, probably as a terminal residue[6].

Because of the reported occurrence of autoantibodies in IgA-deficient patients[7,8] and because of the epithelial origin of BAMP, routine indirect immunofluorescence screening of human biopsy material was undertaken to determine whether human or rabbit antibodies to BAMP could react with human epithelial tissue. The results of this study are summarised in Table 2 and representative data shown in Fig. 1. Characteristics of the homologous system are the fluorescence of the entire cell membrane of the secretory epithelial cells, and in the mammary gland, an accumulation of BAMP on the secretory surface (lumenal) of these cells (Fig. 1*a*). All normal human biopsies were negative but striking cell membrane fluorescence was seen on all diagnosed human epithelial cell tumours, 12% of the renal transplant biopsies, many foetal epithelial cell membranes and in systemic lupus erythematosis (SLE) skin biopsies. The positive human cells (Fig. 1*b–d*) were always epithelial and showed the same characteristic 'rim' fluorescence seen in bovine tissues (Fig. 1*a*). When the sera from patients with precipitating antibodies to BAMP were tested on sections of human mammary carcinoma or normal bovine tissue in the indirect assay, positive fluorescence was obtained with both human and bovine tissues although it was markedly more pronounced with the human tissue.

The specificity of the fluorescence for a specific antigen related to BAMP on human and bovine tissues was confirmed by four different inhibition experiments.

The occurrence of positive pathological biopsies prompted our investigations of serum from these patients. Of those sera available, the correlation between the presence of serum antibodies to BAMP and BAMP-positive biopsies in patients with SLE was (2/2), mammary carcinoma (3/3), melanoma (1/3) and positive kidney biopsies (1/5). The occurrence of precipitating antibodies in the sera of patients suffering from similar disorders as those with BAMP-positive biopsies, sera from patients with related disorders and normal serum donors is summarised in Table 1.

Data were obtained by immunodiffusion assays with or without the addition of polyethylene glycol (PEG)[9]. All positive precipitin reactions could also be detected in the absence of PEG using cross-immunoelectrophoresis. No evidence was obtained for heterogeneity of antibodies to BAMP among patients with different disorders. The greatest apparent amount of precipitating antibodies occurred in patients with mammary carcinoma.

No clear-cut evidence for a BAMP-related tumour antigen in the sera of patients was obtained by: (1) precipitation in agar gel using rabbit antiserum to BAMP and (2) inhibition of capillary agglutination[10]. The sensitivity of the latter was 8 ng of BAMP.

The data presented here are the first to relate previous clinical and certain experimental evidences which correlate IgA-deficiency, incidence of neoplasms, transplantation and autoimmunity through a common immunochemical system—BAMP and anti-BAMP. The best interpretation of our data suggests that BAMP is a bovine protein that is antigenically related to a carcinoembryonic antigen in man. Hence, BAMP can be called a phylo-carcinoembryonic antigen. In

contrast to the previously described carcinoembryonic antigen (CEA) and α-foetoprotein (AFP), the diagnostic feature of our system is the occurrence of precipitating antibodies to BAMP, whereas the reverse is true for CEA and AFP. The absence of BAMP on 127 normal biopsies and seven lymphomas and its presence on all diagnosed epithelial cell neoplasms, argues against the possibility of BAMP being a histocompatibility antigen.

The glycoprotein nature of BAMP is not unlike previously described tumour antigens and the immunochemical and physicochemical properties of BAMP are similar to those reported for CEA[11-13].

Our findings show that anti-BAMP also occurs in conditions not generally regarded as neoplastic. SLE and rheumatoid arthritis (RA) are characterised by autoimmune phenomena and share certain clinical and pathological features[14]. IgA deficiency is not uncommon in patients with SLE[15] and one-third of the BAMP-positive SLE patients in this study had IgA levels lower than 70 mg%. The occurrence of precipitating antibodies to a variety of undefined homologous and heterologous antigens has also been reported in SLE and RA[16]. A correlation between IgA deficiency and autoimmunity has been reported[17] and the association between thymus function and autoimmune disease seems genuine[18]. The presence of BAMP and anti-BAMP in renal transplant patients is not inconsistent with the reported correlation between neoplastic tissue and transplantation[19] or with reports of heterophile antibodies in transplant patients[20].

The data presented here also offer a new interpretation of reports on the occurrence of antibodies to ruminant immunoglobulins in patients with IgA deficiency[1-5]. The presence of these antibodies has generally been ascribed to the greater absorption of macromolecules by the digestive tract of such patients. The reports that IgA-deficient patients also have autoantibodies to human IgA and human IgM[7,8] instead suggests that the occurrence of antiruminant antibodies could be a reflection of an autoimmune phenomenon or immune surveillance defect. In this study, (1) the failure of human sera to precipitate with only a portion of BAMP detected by anti-rabbit BAMP and (2) the greater degree of fluorescence of human carcinoma tissue compared with bovine mammary tissue obtained using human antibodies to BAMP, both suggest that the antibodies in human serum were formed in response to the human BAMP-related antigen and only cross react with BAMP. An antigen has been partially purified from a mammary carcinoma which cross reacts with BAMP and the serum of this patient contains antibodies to the human antigen.

Cell-mediated immunity is generally regarded as most important in the body's elimination of neoplastic tissue[21] and the specificity control at the T-cell level has been suggested to be of great importance in the prevention of autoimmune responses[18,22]. Reports have suggested that complete development of the IgA system depends on a functioning thymus[23-25]. From this, the occurrence of BAMP or anti-BAMP may be correlated with pathological conditions in which a thymic malfunction is probable.

We thank Drs Arthur Ammann, Newton Hyslop, jun., Ira Wong, William Bonney and George Pennick for the sera and biopsy material used in this study. We also thank B. Sue Newman for technical assistance and Renate Brodeur for assistance in preparation of the manuscript.

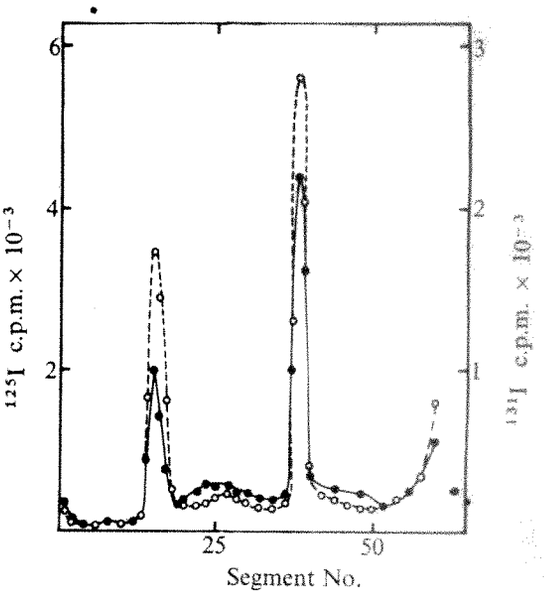

Fig. 1 SDS-polyacrylamide gel electrophoresis of immune complexes between anti-H-2D^a and a ^{131}I-labelled H-2 alloantigen preparation and between anti-H-2K^a and ^{125}I-labelled H-2 alloantigen. The H-2 containing materials were radioactively labelled with iodine by the chloramine T procedure[10]. The immune complexes were isolated by gel chromatography on Sephadex G-200. Gels with an acrylamide concentration of 15% prepared as described by Neville[11] were used. After completion of the electrophoretic separation the gel was divided into segments of 2 mm width and counted for radioactivity in a γ-well type scintillation counter. ●——●, ^{125}I; ○ - - ○, ^{131}I.

Subunit structure of H-2 alloantigens

HISTOCOMPATIBILITY antigens carry the immunological determinants involved in tissue transplant rejection[1]. Recent evience has shown that papain-solubilised HL-A antigens are composed of two polypeptide chains[2,3]. The smaller of the solubilised HL-A polypeptide chains has been shown[4,5] to be identical to β_2-microglobulin and it has also been shown that β_2-microglobulin is physically linked to the HL-A antigens on the cell surface[6–9]. These findings raised the question of whether the major transplantation antigens from other species are composed of subunits. This communication shows that mouse H-2 alloantigens are linked to a small polypeptide chain which is homologous with human β_2-microglobulin.

Papain-solubilised H-2 alloantigens were isolated from 600 A/J spleens essentially as described for HL-A antigens[4]. To achieve further purification, part of the alloantigen containing material was labelled with ^{125}I and ^{131}I (ref. 10) and incubated separately with H-2K^a and H-2D^a alloantisera. The resulting immune complexes were isolated by gel chromatography and subjected to SDS-polyacrylamide gel electrophoresis[11]. From each incubation, only two radioactive bands were apparent after electrophoresis (Fig. 1). Using protein standards of known molecular weight it could be calculated that the two radioactive zones exhibited molecular weights of about 12,000 and 40,000, respectively. Control experiments with normal mouse serum from A/J mice did not give any ^{125}I- or ^{131}I-labelled material appearing in the position of the immune complexes on gel chromatography. Thus, we conclude that highly purified papain-solubilised H-2 alloantigens are composed of two polypeptide chains, irrespective of whether they are coded for by the K or the D end of the histocompatibility locus.

An antiserum against human β_2-microglobulin was incubated with a fraction containing ^{125}I-labelled H-2 alloantigen. The resulting immune complex was isolated and subjected to SDS-polyacrylamide gel electrophoresis. The electrophoretic profile revealed only the presence of the small H-2 alloantigen polypeptide chain which had migrated exactly as human β_2-microglobulin. We have shown that the antiserum used dissociates β_2-microglobulin from the larger HL-A chain[4] and it seems to have the same effect with H-2 antigens. This result strongly suggests that the small H-2 alloantigenic polypeptide chain is highly homologous with human β_2-microglobulin.

The two H-2 polypeptide chains were separated from each other by gel chromatography in 3 M KCl. The smaller polypeptide chain, labelled with ^{125}I, and ^{131}I-labelled human β_2-microglobulin were subjected to acid-urea starch gel electrophoresis[12,13] (Fig. 2). It can be seen that human β_2-microglobulin exhibited an electrophoretic mobility indistinguishable from that of the mouse counterpart. On reduction and alkylation both proteins displayed a retarded mobility compared with the untreated material, signifying that the mouse protein may contain a disulphide loop similar to that of human β_2-microglobulin[14,15].

Further evidence for the great similarity between β_2-microglobulin and the small H-2 alloantigen polypeptide chain was obtained at primary structure level by peptide mapping experiments. Although chymotryptic as well as tryptic digests revealed peptides that were unique for the mouse protein, the majority of the peptides seemed to be shared between the two proteins. These data favour the hypothesis that the small H-2 alloantigen is the mouse homologue of human β_2-microglobulin.

The linkage of the mouse homologue of β_2-microglobulin to the larger H-2 alloantigen polypeptide chain may be a fortuitous result of the solubilisation procedure. Attempts were therefore made to establish a connection between the two polypeptides on the cell surface. It could thus be demonstrated that antibodies against human β_2-micro-

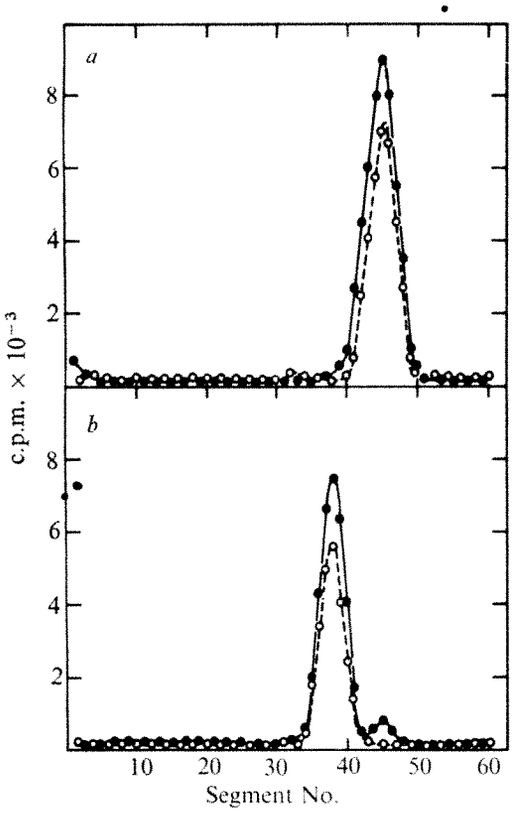

Fig. 2 Urea-starch electrophoresis at *p*H 3.0 according to a modification[13] of the procedure outlined by Edelman and Poulik[12]. *a*, Untreated samples of the small H-2 alloantigen polypeptide chain labelled with ^{125}I and human β_2-microglobulin labelled with ^{131}I. *b*, The same material reduced with 0.1 M mercaptoethanol in 8 M urea for 30 min and alkylated with 0.12 M iodoacetic acid in the dark for 30 min. The radioactive polypeptides were isolated from the labelled antigens by gel chromatography in 3 M KCl. The electrophoresis was run for 2 h at a voltage of 22 V cm^{-1}. After completion of the electrophoresis the gels were divided into segments of 2 mm width and assayed for radioactivity in a γ-well type scintillation counter. ●——●, ^{125}I; O - - O, ^{131}I.

globulin lysed more than 85% of mouse spleen cells in the presence of complement[7]. Fab'-fragments[14] against human β_2-microglobulin could completely abolish the cytotoxic effect of both H-2K^a and H-2D^a alloantisera (compare with ref. 7). Also, antibodies against human β_2-microglobulin cocapped FITC-labelled antibodies directed against H-2K^a or H-2D^a (ref. 6). It is thus conceivable that the mouse β_2-microglobulin counterpart is a true subunit of the H-2 alloantigens coded for both by the K and D ends of the major histocompatibility complex not only when liberated from the cell membrane but also on the intact cell surface.

We thank Dr H. Wigzell for supplying the alloantisera used in this study. The technical assistance of Miss Yvonne Fernstedt is acknowledged. Financial support was obtained from the Swedish Cancer Society and the Swedish Medical Research Council.

Induction of lymphokine production by EAC and of blastogenesis by soluble mitogens during human B-cell activation

Two groups of human lymphocytes are distinguished on the basis of immune effector functions, membrane markers and *in vitro* mitogen reactivity. Thymus-derived (T) lymphocytes mediate cellular immunity either directly or by secreting pharmacologically active lymphokines[1], and are implicated in facilitating antibody responses[2]. In contrast, bone marrow-derived (B) lymphocytes are thought to produce only antibodies. Studies in the guinea pig, however, indicate that, appropriately stimulated, B cells can produce macrophage migration inhibitory factor (MIF)[3]. We have now found that the erythrocyte–antibody (19S)–complement (EAC) rosetting method, used to obtain pure human peripheral blood B cells, activates these B cells to produce mononuclear cell chemotactic (CTX) and mitogenic (MF) lymphokines. Furthermore, we have investigated the mechanism of B cell activation by EAC and the effects of mitogenic lymphokines on human T and B lymphocytes.

T and B lymphocytes were obtained as described in the legend to Table 1. Between 45 and 75% of peripheral blood lymphocytes were recovered as E-rosette-forming cells and 5–35% as EAC-rosette-forming cells. These high rates of recovery suggest that the subsequent biological studies are representative of T and B cell functions.

Purity of T and B cells was assessed by immunofluorescent staining of membrane-associated immunoglobulins, a characteristic of B cells. Different anti-human immunoglobulin sera were used: two conjugated with fluorescein (C20F-341, Meloy Laboratories), and 3031612 (Baltimore Biological Laboratories, Cockeysville, Maryland) and the other with rhodamine (6481, Cappel Laboratories, Dowingtown, Pennsylvania). All sera were titred to find their optimum staining concentrations. Rosetted cells (1.0×10^6) were treated with isotonic ammonium chloride lysing buffer, washed and kept at 3° C. A volume of 0.1 ml conjugated serum was added and the pelleted cells were incubated for 30 min at 4° C, washed three times in chilled azide-BSA buffer and wet mounts were made. In four experiments, the mean purity of T cells was 95% ± 1 and of B cells, 97% ± 2 with < 0.5% monocyte contamination in either population.

Table 1 Blastogeneic responses of human T and B lymphocytes

	T cells		B-EAC		Dissociated B cells	
	N	mean	*N*	mean	*N*	mean
Control	(19)	87±13	(15)	157±33	(4)	135±12
PHA (1 μg per well)	(19)	16,404±2,934	(17)	4,926±981	(4)	5,513±3,404
Con A (10 μg per well)	(14)	9,687±2,471	(12)	1,780±685	(3)	4,002±2,282

T and B cells (93–99% purity) were prepared from FH-separated (30–200ml) heparinised peripheral blood by a modification of a sequential rosetting technique unpublished results of W. West, J. McCoy, T. Doering and R. Herberman. Washed mononuclear cells were sequentially rosetted at 30° C with sheep erythrocytes (E) and foetal calf sera (heat-inactivated E absorbed). T cells were separated from non-rosetting cells on two consecutive Ficou-Hypaque (FH) gradients. NRFC were then rosetted with E coated with (19S) anti-E antibody-mouse complement (EAC) at 37° C and EAC-rosette-forming cells separated on two consecutive FH gradients. B-EAC-rosettes were dissociated with rabbit anti-C3 globulin (1 mg IgC per 1×10^7 cells; Cappel Laboratories) at 37° C for 30 min. Dissociated B cells were separated from EAC on FH gradients, washed and diluted to 2×10^6 viable cells per ml in RPMI-1640 (NIH) supplemented with a final concentration of 0.5% human AB sera and aliquoted in 0.1 ml volumes into microtitre trays. B and T cells with their adherent rosettes cells were diluted and aliquoted in a similar manner. The test mitogens PHA or con A were added in 0.1 ml volumes to triplicate wells and trays cultured for 72–96 h in 5% CO_2–95% air at 37° C; 18 h before collection 3.0 μCi of ^{3}H–TdR (6 Ci mol^{-1}, Schwarz/Mann) was added to each well. Cultures were processed automatically and total radioactivity incorporated into DNA was assessed. *N* represents the number of independent experiments used to calculate the results. Data are expressed as the mean c.p.m. of triplicate cultures ± s.e.

T and B cells with adherent E or EAC rosettes were placed in culture (as described in the Table legends) and stimulated with medium, concanavalin A (con A) or phytohaemagglutinin (PHA). Levels of incorporation of tritiated thymidine (^{3}H-TdR) in control unstimulated cultures in both populations were quite low (Table 1); with a mean of 87 c.p.m. ± 13 for T cells and 157 ± 33 for B cells. Mitogen-stimulated T cells incorporated considerable ^{3}H-TdR and to a lesser degree B cells were also stimulated by soluble PHA and con A.

We investigated whether B cell responses to mitogens were due to PHA and con A adsorbed on the EAC, since particulate mitogens stimulate B cells[4]. B cells were dissociated from erythrocytes with anti-C3 antibody[5] and separated by Ficoll-Hypaque (FH) gradient centrifugation. Dissociated B cells were viable as assessed by trypan blue exclusion and still gave PHA and con A-induced proliferative responses equivalent to B-EAC cell cultures. Even transient EAC binding to C3 receptors may have lowered the threshold for B cell stimulation so that the subsequent interaction with soluble mitogens induced blastogenesis.

We then investigated whether purified T and B cells can be activated by soluble mitogens to make mediators as well as to proliferate. Supernatants from medium, PHA and con A-stimulated T and B cell cultures were assessed for CTX activity as before[6]. Table 2 shows that supernatants from T cell cultures which had been activated with PHA or con A to synthesise DNA also had appreciable CTX activity (30–60 cells per 20 fields), while unstimulated control supernatants, reconstituted after culture with mitogen, had essentially none (8–9 cells per 20 fields). The mean values of the reconstituted controls were equivalent to those obtained with medium. In contrast, all B cell supernatants contained equal levels of CTX activity irrespective of whether they were from unstimulated, reconstituted or mitogen-stimulated cultures. The generation of CTX activity in B cell cultures did not correlate with ^{3}H-TdR incorporation (Table 1). The CTX activity in both control and mitogen stimulated B-EAC cell supernatants was two to five times greater than in supernatants from mitogen-stimulated T cell cultures, suggesting that CTX activity in B-EAC cell culture supernatants was not derived from the few contaminating nonimmunoglobulin-bearing cells. Furthermore, mitogen-stimulated B-EAC cultures did not contain more CTX than supernatants from control cultures. This indicates that the contaminating cells were not producing lymphokines, as would be expected if they were T cells; this is another indication of the purity of our B cell preparations.

To assess whether the attachment through the C3 receptor non specifically induced the production of lymphokines, B-EAC cell rosettes were dissociated with rabbit anti-mouse C3 globulin[5] (as described in Table legends) and dissociated B cells were cultured with or without mitogen. Supernatants from unstimulated B cells dissociated from EAC were devoid of high CTX activity compared with supernatants from cultures of undissociated B-EAC cell rosettes (Table 2). These data suggests that the attachment of EAC to B cells stimulates lymphokine production. But EAC binding was either insufficient to cause concomitant B cell blastogenesis or blastogenesis requires a different signal. In control experiments, E and EA (19S antibody) which do not bind to B cells failed to stimulate either lymphokine production or blastogenesis; however, EA (7S antibody) which binds to B cell membrane Fc receptors also induced B cell lymphokine production (B. F. M., L. C. A., and J. Jardszewski, unpublished data). Therefore, the induction of B cell lymphokine production seems to be facilitated by agents which bind to specific B cell membrane receptors. The biological activity of B cells dissociated from their adherent EAC was further assessed in terms of their ability to produce lymphokines after soluble mitogen stimulation (Table 2). Con A and PHA stimulation of dissociated B cell cultures induced CTX supernatant activity comparable with that of B-EAC cultures and twice as great as those of mitogen-stimulated T cells. The dissociated B cell culture supernatant levels of CTX were too high to be attributed to the low percentage of contaminating immunoglobulin-negative cells; however, we cannot ignore the possible contribution of helper cell effects. Table 2 suggests that with appropriate stimulation both human T and B lymphocytes produce lymphokines. Further, lymphokine was produced in B-EAC cultures in the absence of concomitant blastogenesis; an observation consistent with the reported dichotomy between lymphocyte proliferation and macrophage inhibitory factor synthesis[7,8].

CTX activity in B cell supernatants was not derived from the two chemotactic complement peptides, C3a and C5a. First, B cells purified using EAC prepared with C5 deficient mouse sera still generated CTX activity equivalent to B cells separated with EAC prepared with normal mouse sera and second, the treatment of B cell supernatants with antisera to C3 and C5 did not appreciably decrease their chemotactic activity; specificity of antisera was assayed by immunodiffusion. The CTX activity found in B cell culture supernatants was therefore presumed to be produced by B cells and seems to have physiochemical characteristics similar to those produced by T cells (L. C. A., B. F. M., and B. Chassy, in preparation).

Supernatants from T and B cell cultures were also assessed for MF. We asked two questions: first, could purified T and B cells produce MF and second, could B, as well as T cell MF stimulate pure T or B cells (Table 3).

Table 2 Chemotactic lymphokine activity in T and B lymphocyte culture supernatants

	T cell supernatants			B-EAC cell supernatants			Dissociated B cell supernatants		
	N	reconstituted	stimulated	E/C	*N*	reconstituted	stimulated	E/C	*N*	reconstituted	stimulated	E/C
Medium	(5)	—	9±2	—	(6)	—	93±7	—	(6)	—	22±6	—
PHA (μg ml^{-1})	(9)	9±2	66±3	7.3	(4)	82±2	99±14	1.2	(2)	18±3	104±11	5.7
Con A (10 μg ml^{-1})	(7)	8±1	30±2	3.8	(2)	134±12	142±10	1.1	(2)	18±3	114%11	6.3

T and B lymphocytes at 4 × 10^6 per 2 ml culture (RPMI-1640; 0.5% human AB sera supplemented) with or without stimulant were incubated at 37° C in 5% CO_2–95% air for 24 h. B-EAC rosettes immediately after purification were treated with rabbit anti-mouse C3 globulin (1 mg IgG per 1 × 10^7 cells; 37° C for 30 min with constant shaking). Dissociated B cells were separated from EAC and undissociated B cells by two FH gradient centrifugations. Total viable dissociated B cells were counted by trypan blue dye exclusion, then cells were diluted and cultured as described. Supernatants were collected and tested for CTX activity. The test population of mononuclear cells (MNC) used in the chemotactic assays was separated from human peripheral blood on FH gradients, washed twice in Gey's balanced salt solution (*p*H 7.0) and diluted to 5 × 10^6 cells ml^{-1}. Target MNC and culture supernatants were placed in modified Boyden chambers separated by a 5 μm polycarbonate filter (Nuclepore, Wallabs Inc.). The chambers were incubated for 90 min at 37° C in air[6]; the filters were removed, stained, and the cell migration was quantitated. Results are expressed as the mean number of migrating cells per 20 oil fields ± s.e. of triplicate samples. *N* represents the number of experiments used to calculate the mean. The E/C values represent the ratios of the CTX activity in supernatants from stimulated cultures divided by the activity in their reconstituted controls.

Supernatants from con A-stimulated and reconstituted T cell cultures were passed through Sephadex G-100 to remove most added con A (ref. 9); supernatants reconstituted with con A after incubation served as controls for the mitogenic activity of any residual con A. Since there was no difference in results for autologous and allogeneic secondary cultures the data were combined. Supernatants from con A-stimulated T cell cultures could activate both T and B cells. Reconstituted T cell supernatants had slightly more mitogenic activity than control supernatants, probably due to residual con A. Supernatants from control EAC-B cells CTX activity (144 ± 5 cells per 20 fields) irrespective of the presence of T cells; control unrosetted and unstimulated mononuclear cell supernatants had no activity. Second, the addition of T cells to purified B-EAC rosette cultures in ratios of 1:10 and 1:1 neither suppressed nor increased the generation of B cell CTX activity.

We conclude first that human peripheral blood T and B lymphocytes proliferate in response to soluble mitogens previously thought to stimulate only T cells. One explanation for this is a helper effect by the few contaminating immunoglobulin negative cells. Alternatively the interaction of activated EAC-3 with B cells through their C3 receptors, may have provided an initial signal so that subsequent binding of soluble PHA or con A became sufficient to stimulate B cell blastogenesis[10]. These findings are consistent with reports that human B cells purified on immunoabsorbent columns also respond to soluble mitogens[11,12]. These immunoabsorbents, like EAC rosettes, may lower the threshold for B cell activation by binding to a membrane receptor.

Second, the binding of EAC and EA (7S) to human B lymphocytes induced CTX and MF synthesis but not concomitant blastogenesis. In contrast, PHA and con A-stimulated dissociated B cells to both proliferate and synthesise lymphokines. These data indicate that lymphokine synthesis and blastogenesis are either functions of different lymphocyte populations or require different degrees of membrane stimulation for their initiation. Finally, the demonstration that B lymphocytes produce a mitogenic lymphokine which effects T cells suggests a previously unrecognised mechanism of immune regulation.

This work was supported by the National Institute of Dental Research to Litton Bionetics Inc.

T and B lymphocyte culture supernatants were prepared as described for Table 2. In experiments using con A as a stimulant, control supernatants were reconstituted after incubation with an equivalent concentration of con A (10 μg ml^{-1}) and reconstituted and stimulated (experimental) supernatants (4–6 ml) both passed through 10 ml Sephadex G-100 columns[9] (binding capacities of 300 μg con A per ml of wet G-100). Rosetted T and B target cells were prepared as previously described from allogeneic and autologous donors. A microtray system was used to assess MF activity; 0.1 ml containing 2 × 10^5 viable cells and 0.1 ml or 0.05 ml of each test supernatant or RPMI-1640 added in to each well; assays were performed in triplicate wells for each variable. Trays incubated at 37° C in 5% CO_2–95% air for 72 h; 18 h before collection 3 μCi ^{3}H-TdR was added to each well. Cultures were processed automatically and the total radioactivity incorporated into DNA assessed. *N* represents the number of supernatant pairs assessed with the results expressed as the mean (c.p.m.) ± s.e. The E/C values represent the stimulation index.

to which no mitogen was added and which did not incorporate ^{3}H-TdR also stimulated both T and B cell blastogenesis in autologous and allogeneic secondary cultures. This MF activity was not ascribed to conditioned medium effects since control T cell supernatants had no stimulatory effects. Significantly more blastogenesis occurred in EAC-B-cell-supernatant-stimulated secondary cultures than in secondary cultures to which only medium was added; however, blastogenesis did not approach that produced by con A-stimulated T cell supernatants. Thus, human B cells activated by EAC-rosetting produced MF similar to the MF in supernatants of con A-stimulated T cell cultures which activated both T and B cells. Furthermore, the incubation of purified T cells with EAC induced neither blastogenesis nor MF production indicating that EAC binding to B cells was the cause of MF synthesis.

Further control experiments were performed to assess whether lymphokine production by human B cells resulted from removal of suppressor T cells. First, B-EAC rosettes were formed but not separated from the total peripheral blood mononuclear cell population, and cultured for 24 h. Supernatants from these cultures contained high levels of

Cyclic AMP and Adenyl Cyclase

–we've got the measure of both

The only commercially available cyclic AMP kit for

- Direct assay of plasma cyclic AMP without tedious extraction methods or recovery corrections
- Simple and accurate assay of adenyl cyclase activity free from non-specific interference
- Confidence in results by eliminating errors in crude tissue extracts
- Convenient double linear plotting of results and freeze dried reagents for maximum stability and storage time

Our cyclic AMP assay kit makes use of the high specificity and affinity for cyclic AMP of a highly purified and stabilized binding protein from bovine muscle. This is combined with an improved charcoal separation step. The result is freedom from interference in the assay of adenyl cyclase by materials likely to be present in crude tissue extracts. Also by measuring cyclic AMP formed from cold ATP most of the difficulties encountered in adenyl cyclase assays using labelled ATP are eliminated. Full information available on request.

A new UV Visible &
Spectrophotometer

ACTA M VII UV/Vis. to NIR Spectrophotometer offers the sophisticated researcher the latest analytical and operational flexibility in the UV/Visible Near IR region of 190-3000nm. The high performance features of this instrument provide the user with the ultimate in wavelength accuracy, resolution, and readability. **No other instrument available today features such outstanding capability.**

☐ DOUBLE MONOCHROMATOR-ALL GRATING

A dual grating double monochromator provides unparalleled resolution throughout the wavelength region together with exceptionally low stray light. The resolution is *better* than 0·05 nm in the Visible and UV and *better* than 0·3 nm in the Near IR. The stray light is *better* than 0·0001% in the region 240–500 nm and better than 0·01% at 2740 nm.

☐ HIGH ENERGY + LOW STRAY LIGHT

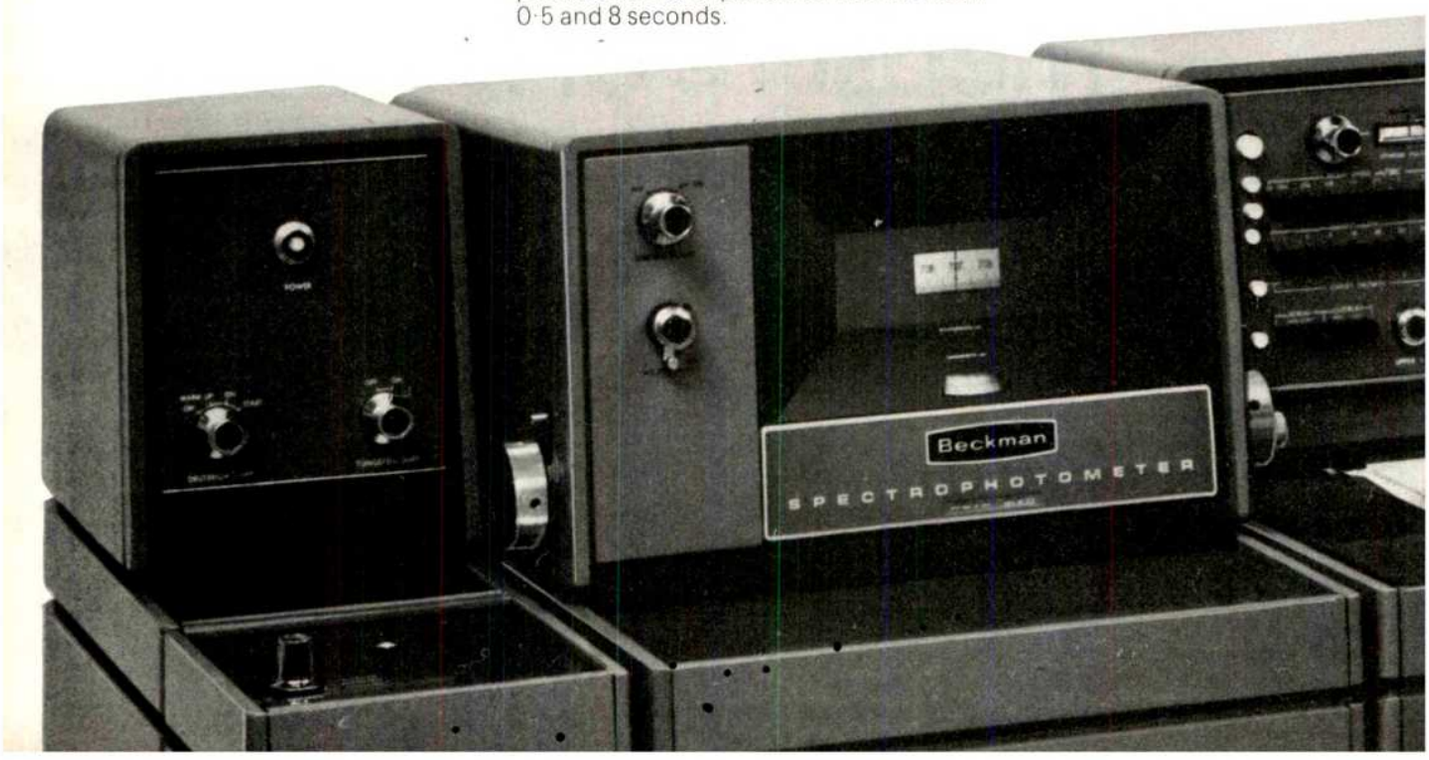
The High energy and low stray light give a large photometric range and high sensitivity with digital readout to the fourth decimal place in Absorbance in the range 0–1·2A and digital readout to three decimal places in the range 0–3A. Ten Absorbance ranges are provided for the integral potentiometric recorder from 0·01 A full scale to 3A full scale.

☐ FIRST DERIVATIVE SCANNING

First derivative scanning is provided with 5 ranges from 0·01–0·2 equivalent absorbance units.

☐ FLEXIBILITY

The flexibility of the system is enhanced by providing 8 wavelength scanning speeds and 7 chart speeds all selected by push button (stepper motors are used both in wavelength and chart drive). Photometric readout can be in Absorbance units, % T., or in Concentration units with 5 possible values of period control between 0·5 and 8 seconds.



☐ LARGE SAMPLE COMPARTMENT

The large sample compartment with 5 inch beam separation and centre focu is particularly accessible. The wide range of accessories available fit on fixed mount rails for reproducible sample positioning.

☐ REPEAT SCANNING

Repeat scanning, either serial or overlay, automatic source change and calibrated zero suppression are standard operating features. To ensur correct operation, a dynode voltage indicator is fitted together with an invalid control light which indicates improper wavelength scan, and chart speed selection.

These outstanding features of the ACTA M VII make it a top-of-the-line instrument for performing sophisticat and dedicated analytical work in a variety of industrial and bio-medical

Near IR Grating from Beckman

applications. This work includes analysis of chemicals, pharmaceuticals, water and air pollution, water and gas in hydrocarbons, hydrogen bonding, and many other industrial and quality control applications. In biomedical research the ACTA M VII is used for high absorbance analyses, protein and amino acid structures and other high-grade, analytical work.

For less demanding applications the dual grating single monochromator ACTA M IV has the operating features of the ACTA M VII being limited only by the capabilities of the single monochromator.

Both ACTA M VII and ACTA M IV are computer compatible and are supported by a wide range of accessories.

Collected Nature

These specially designed Binders make attractive space-saving files for your **Nature**. Bound in durable black imitation leather, lined with grey deer skin and beautifully labelled, each binder will hold up to eighteen copies of **Nature**. Two volumes of **Nature** can be preserved in a single binder, (three binders will hold the six volumes published annually) and there is a white space on the spine to enable you to mark each binder with your own reference to the issues it contains.

These binders are offered for sale singly for £1.85 or in packs of three for £5.00. Both prices include postage by surface mail and V.A.T. To order please complete the coupon below and return it with the appropriate remittance.

NATURE, Macmillan Journals Limited, Brunel Road, Basingstoke, Hampshire RG21 2XS.

Please send me:

1 NATURE BINDER (I enclose £1.85)

3 NATURE BINDERS (I enclose £5.00)

(Payment may be made in any currency at the current rate of exchange) Prices applicable only to orders received before the 30th June 1975. Orders can only be serviced if accompanied by remittance, cheques should be made payable to Macmillan Journals Limited.

Molecular Biology comes of age

This special **Nature** Supplement has been reprinted as a separate publication. First published in the issue of 26th April 1974, **'Molecular Biology Comes of Age'** looks back on the circumstances surrounding the original appearance in **Nature** of Watson and Crick's revolutionary paper on the double helix structure of DNA in 1953. It discusses the development in Molecular Biology up to the present day as well as prospects for the future. Among the distinguished contributors are Crick, Pauling and Chargaff.

'Molecular Biology Comes of Age' takes a fascinating and critical look at a very controversial area of study and will therefore be of special interest to teachers and students as invaluable background material.

Reprints of **'Molecular Biology Comes of Age'** are now available in multiples of five copies at £1.10 surface mail, or £2.00 airmail (10 copies £2.20 or £4.00 and pro rata). Please order copies by completing the order form below and returning it with the appropriate fee.

Altered metabolism of carcinoembryonic antigen in hamsters bearing GW-39 tumours

THE liver is well known for its role in the catabolism of a variety of plasma glycoproteins[1]. Liver-mediated clearance of a tumour glycoprotein antigen, the carcinoembryonic antigen (CEA) associated with human gastrointestinal adenocarcinomas[2], has been demonstrated in dogs and rabbits[3]. Since circulating CEA is being extensively investigated for its diagnostic value in the detection of cancer patients, we were prompted to determine the metabolism of CEA in a xenogeneic species which supports the growth of a CEA-producing colonic cancer.

Female Syrian hamsters, 110–180 g, were heterografted with a CEA-producing colonic adenocarcinoma of human origin continuously propagated in hamsters[4]. CEA, purified from liver metastases of human colonic adenocarcinomas (E. S. Newman, H. J. Hager and H. J. H., manuscript in preparation), was radiolabelled with ^{125}I by the chloramine-T method[5]. Animals were injected intracardially with 7–9 μCi of aggregate-free ^{125}I-CEA (40-80 μCi μg^{-1}) diluted in phosphate buffered saline containing 10% autologous serum. At timed intervals, each animal was exsanguinated by cardiac puncture, its organs were removed and radioactivity was determined in each and in 1 ml of plasma, using a Model 3375 Packard gamma scintillation counter. The radioactive material in the plasma, urine, and liver was characterised by Sepharose 6B column chromatography and by immunoreactivity with goat anti-CEA antibody in the radioimmunoassay developed by Hansen *et al.*[6].

Figure 1 shows that in normal hamsters, 80–90% of the injected radioactivity was cleared by the liver within 5 min. This level of radioactivity was maintained in the liver until 30 min, at which time it began to decrease. Initially, 10–20% of the injected radioactivity was not cleared from the circulation; at 12 h, less than 5% was recovered from either the liver or blood. The accumulation of radioactivity in the urine coincided with its disappearance from the liver and by 24 h, 95% of the injected dose of radioactivity was found in the urine. At all times, the distribution of radioactivity was less than 1.0% in the spleen, kidneys, lungs, heart, and faeces, whereas 10–30% localised in the intestinal tract. The radioactivity reached a peak of 20–35% within the small bowel at 3 h and then declined, while a maximum of 10–15% was recovered in the large bowel 3 h later.

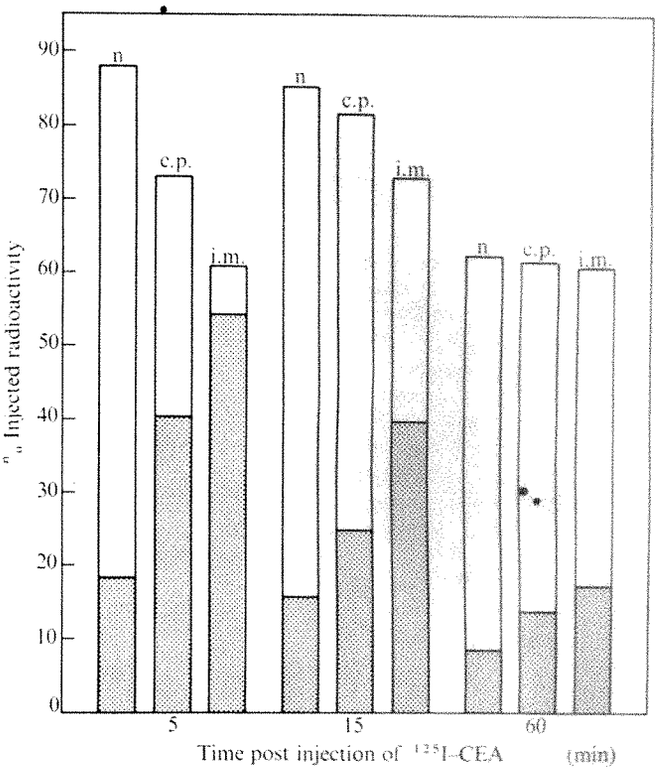

Fig. 1 Clearance of ^{125}I-CEA in normal and GW-39 tumour-bearing hamsters. Shaded area of each bar is the percentage of radioactivity remaining in the plasma of normal hamsters (n), and hamsters with cheek pouch (c.p.) or intramuscular (i.m.) tumours. Clear area of bar is the percent of radioactivity accumulated in the liver. The c.p. and i.m. tumours ranged in size from 2–4 and 20–35 g, respectively.

When radiolabelled CEA was injected into hamsters bearing cheek pouch and intramuscular GW-39 tumours, a decrease in the clearance of plasma radioactivity was observed in hamsters bearing tumours at either site, being more marked in animals with intramuscular tumours (Fig. 1). Initially, the increase in vascular radioactivity corresponded to a decrease in the quantity present in the liver. But as the plasma radioactivity decreased, its level began to rise in the liver, and by 60 min, the radioactivity in both the plasma and liver of tumour-bearing hamsters was similar to that of normal animals. The distribution of radioactivity among the other organs studied in tumour hamsters was identical to that found in normal hamsters.

The radioactivity which was present in a 30 min and 3 h liver sample of a normal hamster was characterised on Sepharose 6B columns calibrated with the preinjection radiolabelled CEA (Fig. 2). The first radioactive peak in a 30 min liver sample cochromatographed with the preinjection antigen, whereas at 3 h, this peak eluted at a slightly lower molecular weight. The second peak in both cases appeared after the total column volume was voided

and represented low molecular weight materials which lacked immunoreactivity with goat anti-CEA antibody. The percentage of this material in the liver was 10–15% from 30 to 360 min. Following perchloric acid (PCA) extractions, the radioactivity sequestered by the liver during the latter times was 80–90% immunoreactive.

The radioactivity not initially cleared by the liver and remaining in the plasma at 5 min was identical, according to Sepharose 6B chromatography, to the preinjection CEA. Subsequently, a low molecular weight, nonimmunoreactive radioactive peak, similar to that in the liver, gradually appeared and accompanied a decrease in the quantity of radioactive material which eluted as the preinjection CEA. By 3 h, the relative percentages of the former and latter were 70% and 25% of the plasma radioactivity, respectively. At 5 min, more than 70% of the plasma radioactivity was immunoreactive before PCA extraction but decreased to 10% by 3 h, owing to the raised levels of the low molecular weight radioactive material. Loss of the latter material during dialysis of 30 min to 3 h plasma samples extracted with PCA yielded material which was 70–75% immunoreactive. All of the radioactivity which accumulated in the urine at 30 min or 24 h eluted as the low molecular weight, nonimmunoreactive material.

Figure 3 shows that a major portion of the radioactivity in both 15 and 60 min plasma from hamsters bearing intramuscular tumours appeared in the void volume after Sepharose 6B chromatography. Although there was a 20% drop in the blood's radioactivity during this time, the relative percentage (45%) of the void volume material remained approximately the same.

Our results with normal hamsters are in general agreement with the report by Shuster *et al.*, in which the metabolism of CEA was investigated in dogs and rabbits[3]. Slight differences in the initial plasma clearance rates are most likely a result of variations in the sialic acid content of the CEA preparations used in the different studies, as previously reported for other serum glycoproteins[7]. We have demonstrated a delay in the blood plasma clearance of radiolabelled CEA in GW-39 tumour-bearing hamsters.

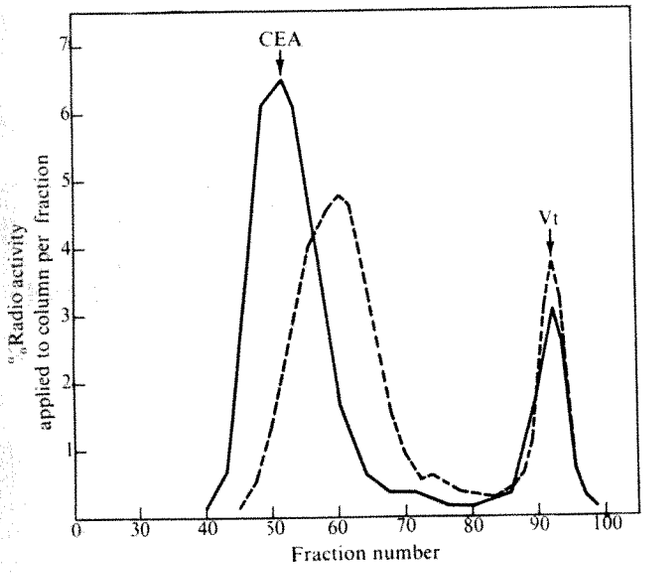

Fig. 2 Chromatography of 30 min (———) and 3 h (– – –) liver radioactivity on Sepharose 6B columns. Livers were homogenised in distilled water, 1:4 (w/v), and centrifuged at 12,000*g* for 30 min. After applying a sample from the supernatant to a 2.6 × 90 cm Sepharose 6B column, 5 ml fractions were collected and assayed for radioactivity. 85 to 98% of the radioactivity applied was recovered. Arrows, total column volume (Vt), and the elution volume of the preinjection radiolabelled CEA.

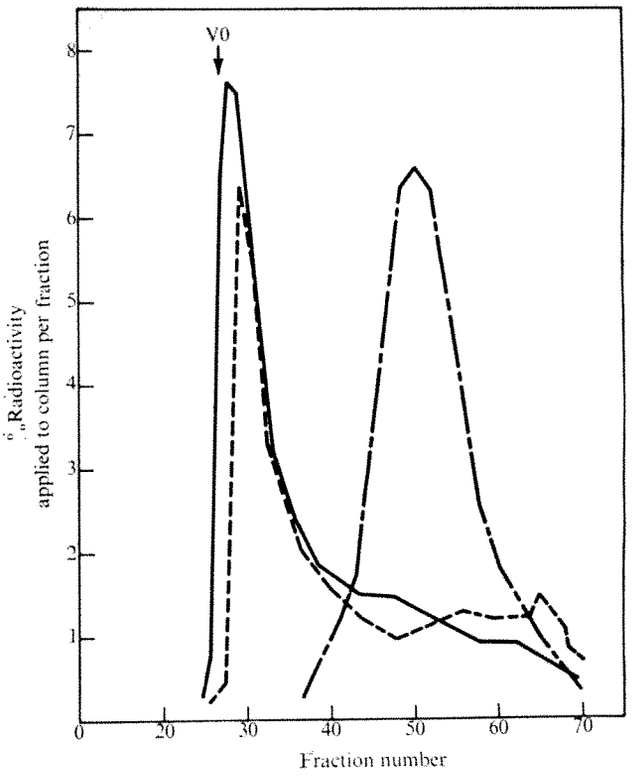

Fig. 3 Chromatography of normal and GW-39 tumour-bearing hamster plasma radioactivity on Sepharose 6B. 85 to 95% of the radioactivity applied was recovered. Arrow, void volume (Vo); (———), 15 min plasma sample from hamster with tumour; (– – –), 60 min plasma sample from hamster with tumour; (—— –), 15 min plasma sample from normal hamster.

Since the GW-39 tumour elicits the formation of a hamster anti-CEA IgM antibody[8], the plasma radioactivite macromolecule which appears in these animals is probably a CEA-antibody complex. Future studies will attempt to determine whether this antibody interferes with CEA clearance or is incidental to a more general state of tumour-induced suppression of liver function.

Regulation of the corticosteroid inducibility of tyrosine aminotransferase in interspecific hybrid cells

TYROSINE aminotransferase (TAT) is not inducible by corticosteroid hormones in heterokaryocytes and hybrid cells resulting from the fusion of rat hepatoma cells with mouse fibroblasts[1,2]. Fusion of rat hepatoma cells with human fibroblasts also results in the loss of TAT inducibility, but because of the unidirectional loss of human chromosomes in the resulting hybrid cells[3], inducibility of TAT is re-expressed in some clones[4]. The suppression or modulation of the expression of TAT inducibility in such hybrid clones seems to be related to presence of the human X chromosome[4]. Since rat–human hybrid clones in which TAT inducibility is suppressed have the same corticosteroid receptor activity as the rat parental cells[4], the absence of inducibility cannot be ascribed to a decrease in corticosteroid receptor activity.

To identify the biochemical event involved in the suppression of the TAT inducibility in interspecific hybrid clones, we have analysed a series of rat–mouse and rat–human suppressed hybrid clones for corticosteroid receptor activity and for their ability to transfer the dexamethasone-receptor complex to the nucleus. The rat hepatoma cells (Fu5AH) used are resistant to 15 μg ml^{-1} of 8-azaguanine and deficient in hypoxanthine-phosphoribosyltransferase (HPRT) activity[5]. They were hybridised with mouse Cl-1D cells which are derived from L cells[6] and are resistant to 30 μg ml^{-1} of BUdR, and with human KOP fibroblasts which are derived from a subject with a translocation of the long arm of the human X chromosome to D-14 [t(14q, Xq)] (ref. 7). Fu5AH cells were fused with either Cl-1D cells or KOP cells in the presence of β-propiolactone-inactivated Sendai virus in Eagle's minimal essential medium (MEM) at *p*H 8.0 (ref. 8). Immediately after fusion, hypoxanthine-aminopterin-thymidine[9] (HAT) selective medium was added to the cultures. After 14 d, colonies of mouse–rat hybrid cells were isolated. These cells were then cloned in microtest plates.

After fusion of human and rat cells the cultures were maintained and passaged in HAT medium to eliminate human fibroblasts. Colonies of hybrid cells were then obtained 4–6 weeks after fusion, permitted to grow and subsequently cloned.

The chromosomes of the parental rat, mouse and human cells and of cells of each hybrid clone were stained by a modification of Seabright's Giemsa banding method[3,10], and a minimum of 20 karyotypes of each hybrid clone was analysed to identify the origin of the chromosomes of the hybrid cells. Chromosome preparations were treated with a solution of trypsin (0.05%) and EDTA (0.02%) (Gibco) for 5 min, rinsed with medium containing 5% foetal calf serum and then rinsed with Hanks solution. The slides were then stained in 2% Giemsa (*p*H 6.8) for 5 min, rinsed with *p*H 6.8 buffer (made by dissolving one tablet of G.T. Gurr *p*H 6.8 buffer in 100 ml water) and dried in humidified hot air.

Of the three parental cells studied, TAT was inducible by dexamethasone only in the rat Fu5AH cells (> four-fold induction) (Table 1).

In all the rat–mouse hybrid clones the TAT baseline activity was not expressed and the enzyme was not inducible by dexamethasone (specific activity = 0). In the rat–human (Fu5AH × KOP) hybrid clone 7, in which the only human chromosome present was the t (14q, Xq), the baseline TAT activity was similar to that of the rat parental cells (Table 1) whereas the inducibility of TAT was significantly reduced in comparison with that of the rat parental cells.

The rat–mouse hybrid clones contained between 83 and 103 chromosomes which could be identified by Giemsa banding (Fig. 1, Table 1). In these clones, most of the chromosomes of the rat and mouse parental cells were retained (Fig. 1), but occasionally rat chromosomes were preferentially lost.

Table 1 Induction of TAT in rat–mouse and rat–human hybrid cells

Almost confluent monolayers of parental and hybrid cells were kept in serum-free medium with or without 10 μM dexamethasone for 18 h. The cells were collected after centrifugation at 800*g* for 10 min at 4° C, washed, and resuspended in extraction medium (0.15 M KCl, 1 mM EDTA, 0.1 mM potassium phosphate buffer at *p*H 7.6). This suspension was sonicated by two 10 s bursts with a chilled probe of Branson sonifier at a setting of 5 A. The sonicated suspension was immediately centrifuged in a RC-2 Sorvall centrifuge at 20,000*g* for 15 min at 4° C. The supernatant solutions were tested for TAT by the method of Canellakis and Cohen[11] and for proteins by the method of Lowry *et al.*[12].

* TAT specific activity = μmol *p*-hydroxyphenyl pyruvate formed per 10 min (37° C) per mg of protein.

Such chromosomal loss seemed to be limited and usually involved less than 40% of the rat chromosomes (Fig. 1).

To survive in HAT medium[4], the rat–human hybrid cells had to retain the long arm of the human X chromosome which was translocated to D-14[7] (Fig. 2), since the human HPRT gene is located on the long arm of the X chromosome[7].

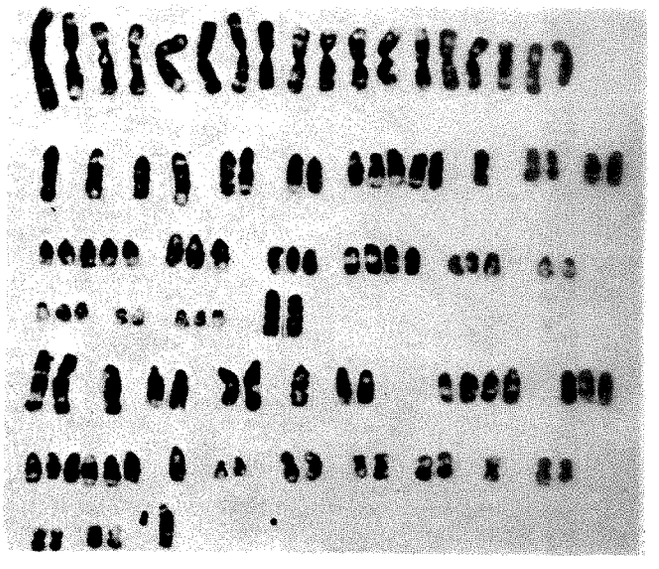

Fig. 1 Rat–mouse hybrid Cl 18. All the mouse Cl-1D chromosomes are present in this clone (upper four rows). Forty rat chromosomes are present in this hybrid (last three rows).

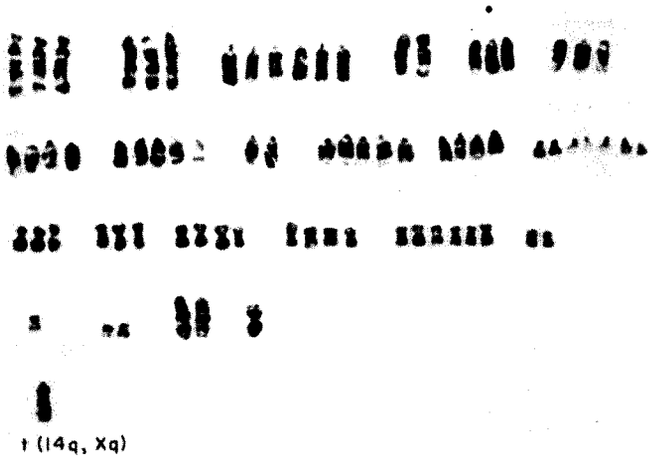

Fig. 2 Rat–human hybrid Cl 7. Seventy-five rat chromosomes are present in this hybrid. Only the human t (14q, Xq) chromosome is present in this clone.

As Table 2 shows, both rat and mouse parental cells displayed corticosteroid receptor activity. The amount of receptor activity was higher in the mouse parental cells (Table 2), in which TAT could not be induced by dexamethasone (Table 1). The KOP cells, as well as WI38 human fibroblasts[4], had low amounts of receptor activity (Table 2). Two noninducible mouse–rat hybrid clones (Table 1) displayed corticosteroid receptor activity which was higher than that of the parental mouse and rat cells (Table 2). The rat–human hybrid clone 7, in which TAT was only slightly inducible by corticosteroids, displayed higher dexamethasone-receptor activity (Table 2) than the rat hepatoma parental cells.

As Table 3 shows, transfer of radioactive dexamethasone to the nucleus proceeded to the same extent in both rat Fu5AH and mouse Cl-1D cells. In the three rat–mouse hybrid clones, in which TAT was not inducible (Table 1), the percentage of radioactive dexamethasone recovered in the nuclei at various times after exposure to the hormone was slightly higher than in the rat and mouse parental cells.

In the rat–human hybrid clone 7, the bound dexamethasone nuclear transfer proceeded to the same extent as in the Fu5AH parental cells (our unpublished results).

Since the rat–human hybrid cells that retained the human X (long arm)/D-14 chromosome had a much lower TAT inducibility than did the rat Fu5AH cells (Table 1), the gene(s) modulating TAT inducibility by corticosteroids seems to be located on the long arm of the human X chromosome. Previous studies excluded this role for the human D-14 chromosome[4].

Our results indicate that noninducibility of TAT in rat–mouse or rat–human hybrid cells cannot be attributed to an absence or decrease of dexamethasone-receptor activity. In fact the rat–human hybrid clone 7 in which TAT was only slightly inducible by dexamethasone had dexamethasone-receptor activity higher than that of the rat parental cells. In addition the mouse–rat hybrid cells have more dexamethasone-receptor activity than either of the parental cells. It is thus possible that in this case fusion of two cell types, both with dexamethasone-receptor activity, results in the formation of a hybrid cell with combined receptor activity of the two parental cells.

In all the clones tested in which TAT was not inducible but which had dexamethasone receptor activity, the transfer of radioactive dexamethasone to the nucleus proceeded to the same or greater extent than in the rat or mouse parental cells, indicating that the biochemical event which is missing in these noninducible hybrid clones is not the transfer to the nucleus of the dexamethasone-receptor complex. Therefore, the regulation of the inducibility of TAT in interspecific hybrid cells must take place either at the level of the binding of the dexamethasone receptor complex to the chromatin or at the transcriptional or post-transcriptional level. These problems are now being investigated.

Table 2 Corticosteroid receptor activity of parental and hybrid cell lines

Cell line	Receptor activity (% hormone binding)	TAT inducibility
Fu5AH	21	++++
Cl-1D	45	−
KOP	4	−
Rat–mouse Cl 5	71	−
Rat–mouse Cl 18	67	−
Rat–human Cl 7	32	+

Cytosols of the cell lines were incubated for 90 min at 0° C with 2 nM 1,2,4-^{3}H-dexamethasone (New England Nuclear Corp.). A load sample of 0.5 ml was added on a 10 ml syringe column of Sephadex G-25 and eluted with 1 mM phosphate buffer (*p*H 7.6). Pre-bound, bound and unbound pools were collected and radioactivity of the pools was determined in a scintillation mixture containing Triton-X, toluene and methanol fluor[13]. These experiments were done essentially as described earlier[13]. Percentage binding was calculated by the following formula:

$$\frac{\text{c.p.m. bound pool}}{\text{c.p.m. load sample}} \times 100 = \% \text{ binding}$$

Using radioactive dexamethasone at this level in glucocorticoid responsive cells in culture we observed that only one major dexamethasone-bound macromolecule appears on ion-exchange chromatography which accounts for about 95% of the binding[14]. This fraction is identical to the binder II dexamethasone binding protein of rat liver cytosol which has been shown to be the major hormone receptor protein[15]. In addition, when this level of radioactive dexamethasone is used in *in vitro* binding experiments with adrenalectomised liver cytosol, there is only one major peak on ion-exchange chromatography which is characterised as binder II, the hormone receptor (unpublished experiments). Thus, the values reported for binding of ^{3}H-dexamethasone in cytosol represent about 95% hormone receptor.

Table 3 Nuclear transfer of ^{3}H-dexamethasone in rat–mouse hybrids

Cell line	% Nuclear transfer 2 h	4 h	6 h	18 h
Fu5AH	17.8	25.9	34.1	20.5
Cl-1D	26.9	26.5	23.4	28.1
Rat–mouse Cl 5	33.6	28.1	30.6	41.4
Rat–mouse Cl 8	ND**	56.3	42.1	48.6
Rat–mouse Cl 10	ND**	43.1	54.5	49.3

Almost confluent monolayers of parental and hybrid cells were exposed to 3.3×10^{-8} M 1, 2, 4-^{3}H-(N)-dexamethasone (specific activity 21.2 Ci mmol^{-1}) in serum-free medium. At different intervals the cells were trypsinised, centrifuged and washed three times in ice cold phosphate-buffered saline (PBS). The cells were resuspended in hypotonic reticulocyte standard buffer (RSB), composed of 10 mM NaCl, 10 mM Tris-HCl, *p*H 7.4, and 1.5 mM $MgCl_2$, and homogenised. The cytoplasmic fraction was centrifuged in a RC-2 Sorvall centrifuge at 20,000*g* for 15 min at 4° C. The nuclei were stripped of the outer nuclear membrane by double detergent procedure according to the method described by Penman[16]. The percentage of nuclear transfer of the dexamethasone-receptor complex was determined by the following formula:

$$\% \text{ Nuclear transfer} = \frac{\dfrac{\text{c.p.m.}}{\text{mg of nuclear proteins}}}{\dfrac{\text{c.p.m.}}{\text{mg of nuclear proteins}} + \dfrac{\text{c.p.m.}}{\text{mg of cytosol proteins}}} \times 100$$

We conclude that the activity of the hormone receptor has indeed been measured by our techniques for the reasons set forth in Table 2. Furthermore, nuclear translocation experiments ascertain the presence and biological activity of the receptor as shown by the results described in this table.

New biological activity following intravascular activation of the complement cascade

ACTIVATION of the complement cascade (C_1–C_9) by the classic or alternate pathways is associated with the development of several biological activities[1]. These include the elaboration of chemotactic factors (C_{3a}, C_{5a}, and a trimolecular complex $C_{\overline{5,6,7}}$), opsonic activity associated with the formation of C_{3b} from the third component, anaphylatoxin activity associated with the formation of C_{3a} and C_{5a} from the third (C_3) and fifth (C_5) components, and lysis of certain cells after the formation of lesions at the cell surface associated with fixation of the eighth (C_8) and ninth (C_9) components. We have detected another activity which follows intravascular activation of the complement cascade with the elaboration of the low molecular weight factor that produces an immediate neutropenia followed by marked neutrophilia.

Activation of the complement cascade intravascularly by the alternate pathway was achieved in New Zealand White rabbits or Hyline Sandy Lop rabbits, weighing approximately 2.5 kg, by intravenous injection 0.6–1.0 ml of purified cobra venom factor or 50 mg of a suspension of inulin (Sigma). The CVF was purified from the crude venom of *Naja naja* (Sigma) on DEAE cellulose and Sephadex G-200 columns after the method of Ballow and Cochrane[2]. The complement activators were injected directly into the marginal ear vein of the rabbit and sequential heparinised venous blood samples were obtained. Leukocyte counts and Wright-stained differential counts were performed by standard techniques.

Figure 1 shows the effects of intravenous administration of the two activators of complement on neutrophils. A profound neutropenia occurred within 60–120 s and this was followed by neutrophilia within 0–3 h. Figure 2 shows the time course of depletion of the opsonin activity and antigenic levels of C_3 in rabbit serum after challenge with CVF. Opsonic activity was determined by counting the total number of zymosan particles ingested in 100 neutrophils (PMN). Values are expressed as percentages of a parallel control. The alterations in PMN counts in Fig. 2 coincided more closely with depletion of opsonic activity than with reduction in antigenic C_3 levels.

To determine whether the biological activity was associated with complement activation, rabbits were first depleted of complement by sequential injections of purified CVF as described by Brown[4]. When the antigenic C_3 level was less than 10% the animal was challenged with 1.0 ml of CVF. In the complement-depleted animal there was little effect on PMN counts after rechallenge with 1.0 ml of CVF.

Further substantiation that the biological effect was associated with complement was obtained by infusing 40 ml of fresh rabbit plasma into an animal that was complement-depleted but still had circulating CVF. It has been demonstrated that, after sequential intravascular administration of CVF, the CVF continues to circulate until antibodies against it are formed[5]. Ths infusion of the 40 ml of fresh heparinised plasma into a complement-depleted rabbit (opsonic index <10%) caused acute neutropenia followed soon by neutrophilia (Fig. 3).

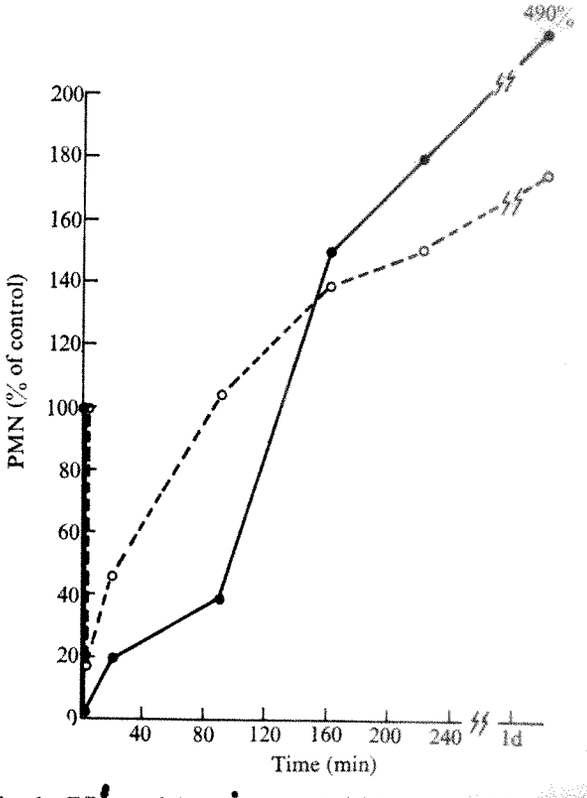

Fig. 1 Effects of intravenous administration of 1.0 ml of CVF (●) or 50 mg of inulin (○) on rabbit peripheral blood PMN counts. Values are expressed as percentages of control value, which was obtained 1–5 min before infection. The values are representative experiments, selected from more than five individual observations, all done in duplicate.

Both CVF and inulin activate complement by the alternate pathway which results in formation of a C_3-convertase which then activates C_3–C_9 (ref. 1). To identify further the components upon which biological activity might depend, CVF was injected into C_6-deficient rabbits. Acute neutropenia followed by neutrophilia occurred, suggesting that the biological activity was dependent on either C_3 and/or C_5 (data not shown).

Further studies were then designed to further characterise the active factor. Fresh plasma (15 ml) was treated with either CVF (1:10 v/v) or 6 mg ml^{-1} of inulin suspension. The mixtures were reacted for 15 min at 37° C and immediately filtered at 4° C through a UME 20,000 Amicon Diaflo filter. To enhance the filtration the plasma was first diluted 1:1 with sterile, isotonic saline. The filtrate was collected and then filtered through a 0.4 μm Millipore filter before infusing it into the rabbit ear vein. Appropriate saline controls were performed.

Figure 4 shows that the biological activity could be recovered in the filtrate. The small pore size would exclude CVF (molecular weight >180,000) and the C_{3b} immune adherence molecule (molecular weight ~150,000). The low molecular weight fraction recovered after treatment of plasma with CVF or inulin caused a biphasic curve following infusion. There is no explanation for this difference from *in vivo* adminstration of CVF or inulin. Low molecular weight filtrate produced very little neutropenia when the plasma treated *in vitro* with CVF was obtained from an animal first depleted of C_3 by sequential doses of CVF. There was, however, pronounced neutrophilia, suggesting that neutrophilia follows activation of less substrate or that it is determined by a different mechanism.

Preliminary studies suggest that the low molecular weight factor acts directly on PMN and that the cells are removed by sequestration rather than lysis (our unpublished observations).

Alterations in neutrophil kinetics during acute inflammatory states have interested investigators for some time. Some of the most intriguing early observations were made by Andrewes[6]. This investigator demonstrated in rabbits that acute neutropenia followed intravenous administration of the live Gram-negative bacteria, and antigen–antibody complexes. Neutrophilia occurred later. Reactions to Gram-positive bacteria were mild unless animals were previously

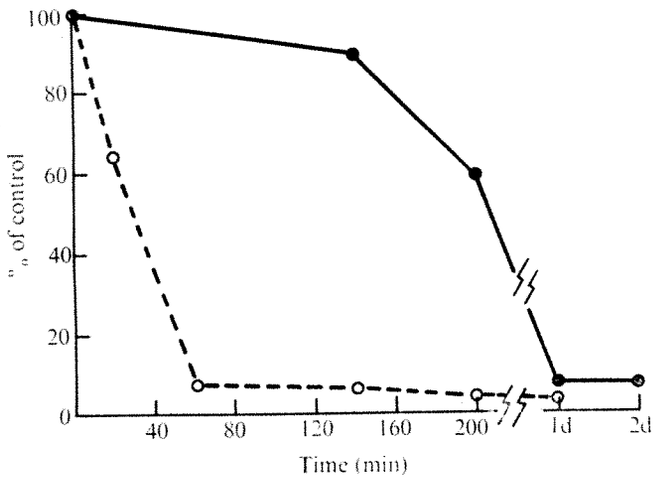

Fig. 2 Effect of two sequential doses of 1.0 ml CVF on antigenic C_3 levels of serum (●) and zymosan opsonic index (○). The first dose of CVF was given at zero time and the second at 160 min. Antigenic C_3 levels were measured by radial immudiffusion using goat anti-rabbit C_3 (ref. 3). The opsonic index for zymosan was obtained by counting the number of intracellular zymosan particles in 100 PMN (100 particles: 1 PMN) after incubating in a shaker bath at 37° C for 15 min.

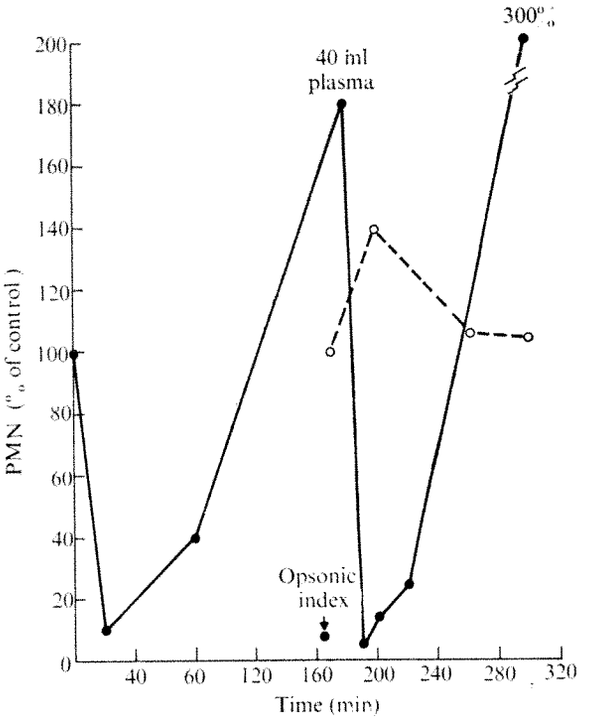

Fig. 3 Effect of infusion of 40 ml of fresh plasma in a rabbit which received 1.0 ml of CVF at zero time (●). The opsonic index for zymosan at the time of plasma infusion was 8% of control. A saline control in a normal rabbit is included (○).

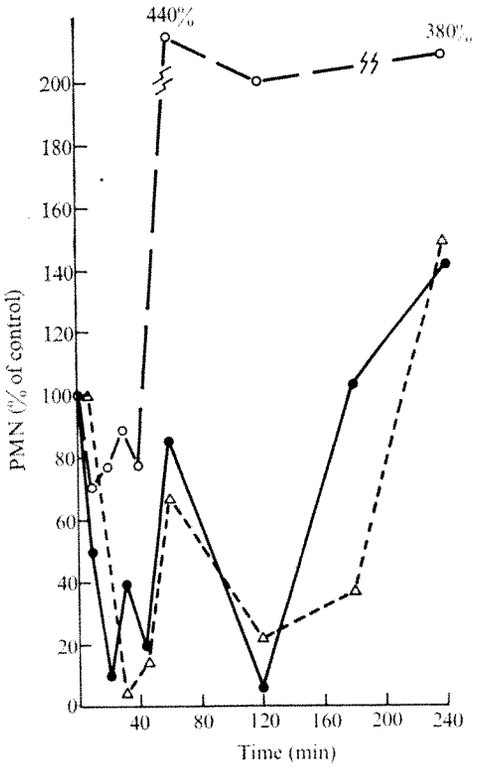

Fig. 4 Effects of infusion of 15 ml of low molecular weight filtrate (< 20,000) on rabbit PMN counts. Before filtration for approximately 2 h through an Amicon Diaflow UME 20,000 filter, 15 ml of fresh plasma was incubated with either CVF (1:10 v/v) or inulin 6 mg ml^{-1} plasma. The plasma was diluted 1:1 with saline before filtration in order to increase the rate of filtration. ●, Filtrate from CVF treated plasma; △, filtrate from inulin-treated plasma; ○, filtrate from CVF treated plasma obtained from a rabbit that had received for sequential doses of CVF (0.7 ml) which reduced the antigenic C_3 level to 20% of control before the time plasma was collected.

immunised. Most PMN were sequestered in the lung and there was no evidence that their destruction was the cause of the profound neutropenia. Interpreted in the light of contemporary knowledge, these early studies suggest that the acute neutropenia may have been complement dependent. With Gram-negative bacteria, the complement cascade would be activated by endotoxin[1]. The reaction to Gram-positive bacteria would be mild unless it was enhanced by the presence of specific antibody, after which the complement cascade would be activated by the antigen–antibody complex[1]. Moreover, both neutropenia and neutrophilia may occur in humans during acute bacterial infection, and the shock syndrome of infection is associated with activation of the complement cascade[7]. Neutropenia follows the injection of endotoxin into both humans and experimental animals and during this time the cells are primarily sequestered in the pulmonary capillaries[8]. Recent studies have indicated that the neutropenia induced after infusion of viable Gram-negative bacteria into the blood of subhuman primates is diminished if the animals are first depleted of the complement by CVF (ref. 9). In our investigation the possibility of contamination of the CVF, inulin or low molecular weight fraction by endotoxin was considered. This was excluded by constant temperature measurements for up to 3 h in rabbits receiving each of these. No significant alteration in rectal temperature was observed in any animal, thus making contamination with endotoxin highly unlikely.

A neutrophilia has been observed several hours after the infusion of CVF, but careful studies of time points earlier than 1 h were not done[5,10]. The magnitude of the neutrophilia was somewhat less than we observed and the reasons for this are not evident at present. A possible association of leukocytosis with complement activation has been recorded by Rother who observed that factors released during complement activation induce release of leukocytes from bone marrow[11].

This investigation indicates that the alternate pathway activation of the fluid phase by CVF or by inulin is associated with alterations in PMN kinetics. The changes depend on elaboration of a factor of low molecular weight (< 20,000) which may be derived from either the C_3 or C_5 molecule. This factor may be responsible for alterations in PMN during acute inflammation.

Evidence that most noradrenaline is stored without ATP in sympathetic large dense core nerve vesicles

THE concept that catecholamine (CA) in sympathetic nerve vesicles is stored together with ATP, in a fixed molar ratio of 4/1, is so widely accepted that it is even quoted in general textbooks on physiology and pharmacology for medical students[1-3]. This fixed ratio of CA to ATP has been convincingly demonstrated in purified preparations of adrenomedullary vesicles[4,5], whereas the evidence concerning the ratio of noradrenaline (NA) to ATP in sympathetic nerve vesicles has been based on preparations from bovine splenic nerves[6-9], rat heart[10] and rat vas deferens[11] contaminated to an unspecified extent with other organelles such as mitochondria. The aim of the present study was to determine the molar NA/ATP ratio in a highly purified preparation of bovine splenic nerve vesicles.

Large dense core vesicles were isolated from bovine splenic nerves using differential and density gradient centrifugation[12,13]. The supernatant obtained after centrifugation of the nerve homogenate at $10{,}500g_{max}$ for 10 min was layered on sucrose-D_2O gradients (linear from 0.25 M to 0.6 M with a step of 1.2 M in the bottom). The gradients were spun at 280,000 g_{max} for 90 min in a SW 40 rotor (Beckman). The band just above the bottom step (fraction III) in the gradients was taken out, diluted three-fold with isotonic sucrose and centrifuged at $10{,}500g_{max}$ for 10 min. The supernatant obtained was centrifuged at $20{,}000g_{max}$ for 10 min and the supernatant from this centrifugation was spun at $230{,}000g_{max}$ for 20 min.

Each pellet was resuspended in 1.5 ml 20 mM K-phosphate buffer (*p*H 7.3); 0.5 ml was used for determination of cytochrome oxidase as a mitochondrial marker enzyme[14]. The rest (1 ml) was extracted with 0.4 M perchloric acid and then diluted with distilled water to 2 ml. After removal of the protein precipitate, 1 ml was used for fluorimetric determination of NA (ref. 12) and the remaining 1 ml was titrated with Tris-buffer and KOH to *p*H 7.0–7.4. The perchlorate precipitate was carefully removed by centrifugation. The supernatant was used for ATP assay by the firefly method[15]. The recovery of ATP added as internal standard ranged from 59–73%.

The ATP values were corrected for the loss actually measured in each individual experiment. The protein precipitate was solubilised in NaOH and protein was determined by the Folin method.

NA storage particles and mitochondria from splenic nerve sedimented to about the same level in the density gradients[12]. But a separation of NA storage particles and mitochondria could be achieved by differential centrifugation of the diluted gradient fraction as shown in Fig. 1. Cytochrome oxidase activity was highest in the first two pellets obtained after low speed centrifugations, while most of the NA was found in the last pellet which was obtained after high speed centrifugation. In this way about 80% of the cytochrome oxidase activity could be removed while still more than 60% of the NA was retained in the particles.

The high speed sediment with the lowest cytochrome oxidase activity was used for determination of the NA/ATP ratio. In the first few experiments there was a great variability in NA/protein ratio due to variable *post mortem* delay at the slaughter house before the nerves could be chilled with ice. When special precautions were taken to shorten the delay to 15–20 min, the average NA/protein ratio was 5.30 ± 0.74 μg mg^{-1} (s.e.m., $n = 11$) and the molar NA/ATP ratio 7.32 ± 0.30.

The original density gradient fraction (fraction III) consisted mainly of large dense core vesicles (750 Å), contaminated almost exclusively with mitochondria according to biochemical[12] and morphological analyses[16]. As seen in Fig. 1 most of the mitochondria likely to contain appreciable amounts of ATP, could be effectively separated from the NA storage particles, as has also been confirmed by morphological studies[16].

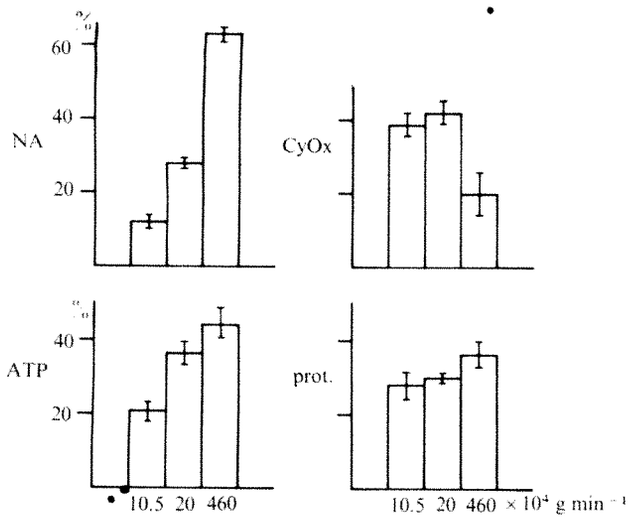

Fig. 1 Distributions of NA, ATP, cytochrome oxidase (CyOx) and protein (prot.) in the three sediments. These were prepared from a 'nerve vesicle fraction' (obtained from a density gradient after ultracentrifugation) by fractional centrifugations at 10,500 g_{max} for 10 min; 20,000g_{max} for 10 min and 230,000g_{max} for 20 min. The values are expressed in percentages ± s.e.m. Each bar represents the mean of at least four experiments.

The much more complete removal of cytochrome oxidase than of ATP indicates that the ATP sedimenting together with NA truly belongs to the NA storage particles. The possibility of contamination with mitochondrial fragments containing ATP but not cytochrome oxidase (outer membrane fractions) cannot be ruled out. But these particles would probably not sediment to the same level in the density gradients[14].

It was not possible to get rid of all the cytochrome oxidase in the final sediment. According to the morphological studies[16] the mitochondria constituted a few per cent of all the particles. Therefore the NA/ATP ratio was certainly slightly higher than 7.3 in the NA storage particles in the final sediment.

We have not excluded the possibility that there were nerve vesicles with relatively higher ATP content which were lost during the first centrifugations. The overall NA/ATP ratio was however found to be 5.1/1 in the original preparation containing at least 10% mitochondria according to morphological analysis[16], so it is quite possible that the NA/ATP ratio also was higher than 4/1 in the lost vesicles.

The 'true' *in vivo* ratio of NA to ATP may be even higher than the value 7.3 obtained in the present study. Since there is evidence that thermal activation leads to a selective loss of NA without concomitant loss of ATP[8], it seems probable that *post mortem* delay at body temperature reduces the NA/ATP ratio of the vesicles. Thus, when the delay was 30–40 min the NA/protein ratio was about 2 μg mg^{-1} and the molar NA/ATP ratio was about 3.5. When the delay was reduced to about 10 min, vesicle preparations with a NA/protein ratio of 10 μg mg^{-1} could be obtained. The NA/ATP ratio in these preparations was 7–12.

Extrapolation to zero time[13] suggests that the NA/ATP ratio *in vivo* may be as high as 20/1 which would indicate that only 20% of the NA in these sympathetic nerve vesicles could be stored in the postulated NA/ATP complex. High values for the NA/ATP ratio have been observed previously; a level of 7.5–12 has been calculated to occur in sympathetic large dense core vesicles[17]. Moreover, in a series of studies on phaeochromocytoma tumours a wide range of CA/ATP ratios were found, from 8 to as much as 35 (refs 18, 19). It may be of further interest that cholinergic nerve vesicles seem to store acetylcholine in a molar ratio to ATP of 10/1; and 5/1 in the two discernable pools[20].

The occurrence of other nucleotides in sympathetic nerve vesicles cannot be ruled out, but only trace amounts of such material, including ADP, could be detected in partially purified splenic nerve vesicles (DaPrada, personal communication).

This study concerns the NA storage particles in nerve trunk. It is possible that the vesicles in the nerve terminals have a relatively higher content of ATP, corresponding to the proximo-distal increase in NA/protein ratio[21]. But preliminary studies do not support this possibility, since no significant rise was found in the ATP/protein ratio in the vesicles isolated from the intrasplenic distal part of the nerve trunk, compared with vesicles from the proximal part, while the NA/protein ratio increased markedly.

The present results provide very strong evidence that a major proportion of the NA in the sympathetic nerve vesicles is stored differently from the bulk of the CA in the adrenomedullary vesicles. This is further supported by the findings of striking differences in kinetic properties[8,12]; between nerve and adrenomedullary vesicles.

The nerve vesicles are, for example, very resistant to osmotic shock, but they lose NA rapidly during thermal activation, while the adrenomedullary vesicles behave in the opposite way[8]. Furthermore, the nerve vesicles have a very low content of soluble proteins such as chromogranin A compared with the chromaffin vesicles[9]. The nerve vesicles may contain a small NA/ATP/soluble protein complex of the same kind as that which predominates in adrenomedullary vesicles; it seems possible that this complex in nerve vesicles is functionally insignificant and may represent an evolutionary dead end. If ionically bound, most of the NA in nerve vesicles has to be bound by negatively charged constituents other than ATP such as phospholipids.

We thank I. Dahlin and I. M. Eriksson for technical assistance; Farmek, Uppsala for supplying the nerves and the Swedish Medical Research Council and Magnus Bergwalls Stiftelse for financial support.

(+) and (−)-bicuculline methochloride as optical isomers of a GABA antagonist

THE discovery by Curtis *et al.*[1], that bicuculline would antagonise both the depressant effects of microiontophoretically applied γ-aminobutyric acid (GABA) and certain strychnine resistant central inhibitions has provided further support for the view that GABA might be a central transmitter. Their studies have also stimulated much thinking and research into the structural relationship of GABA and its receptor. On the basis of examination of Dreiding stereomodels of GABA and bicuculline, the Canberra group suggested that the nitrogen atoms and the three atoms associated with the carboxylate in GABA (O = C − O) could be isosteric with the nitrogen atom and the O = C − C grouping in bicuculline[1]. Indeed, recent physiochemical work[2] on the two substances indicates that the distance from the onium group to a carboxylate oxygen in GABA is fixed at between 5.2 and 5.8 Å and this agrees well with a distance of 5.6 Å between the equivalent groups in bicuculline. It would therefore seem reasonable to suppose that the GABA antagonist properties of bicuculline are due to the occupation of the GABA receptor by a part of the bicuculline molecule that is isosteric with the biologically active conformation of GABA[1].

Closer inspection of the portion of the bicuculline molecule that is isosteric with GABA reveals that it contains two asymmetric centres and thus four optical isomers are possible. Such variation in the optical properties would be unlikely to change interatomic distances along the skeleton of the molecule and so may not affect the potency as a GABA antagonist. If, on the other hand, the stereochemical requirements for combination with the GABA receptor are more subtle, then different optical isomers would be expected to have widely differing potencies. All pharmacological experiments so far performed with bicuculline[3] have used the commercially available (+) form (K & K Chemical, Pierce Chemical) and, so we thought it important to examine the properties of the (−) isomer. Although the (−) form occurs in nature[4] it is rare and we have therefore prepared it by synthesis from (−) β-hydrastine[5].

In comparing the biological activities of the two stereoisomers of bicuculline certain problems arise, chiefly associated with their very low solubility at biological *p*H, and this has already led to dispute over the efficacy of the (+) isomer[6,7]. This would obviously lead to uncertainty over the correct interpretation of a negative effect with the (−) form. More recently (+) bicuculline methochloride has been shown to be an effective GABA antagonist and as this substance is about 100 times more soluble in water than bicuculline base, its use, particularly in microiontophoresis experiments, is easier and gives more reproducible results[8]. As the asymmetric centres are not affected by methylation we have chosen to prepare the methochlorides from our samples of (+) and (−)-bicuculline and to compare the relative biological activities of these derivatives.

All experiments have been performed in piebald Lister rats anaesthetised with urethane, and respiring spontaneously. Microiontophoretic techniques were as previously described[9] and all recordings of unit activity were extracellular. Neurones were located in the cerebral cortex and cuneate nucleus, and (+)-bicuculline methochloride (10–50 nA, from 5 mM solution in 150 mM saline) consistently antagonised the depressant action of GABA on these neurones and produced concurrent excitation. (−)-Bicuculline methochloride (prepared in a similar solution, 10–100 nA) applied to the same neurones, from the same pipette, was ineffective as a GABA antagonist but produced neuronal excitation in a similar manner to the (+) isomer (Fig. 1).

Presynaptic inhibition was measured in the cuneate nucleus by analysis of the evoked potential recorded there in response to stimulation of a forepaw ipsilateral to the recording electrode. The amplitude of the positive-going potential (P wave) was taken as an index of presynaptic terminal depolarisation[10]. (+)-Bicuculline methochloride (0.5 mM solution in normal saline), applied topically to the medulla, consistently and reversibly antagonised presynaptic inhibition in the nucleus, whereas (−)-bicuculline methochloride (4 mM solution in normal saline) was without effect on the P wave (Fig. 2).

The relative convulsant potencies of the two isomers were tested by making microinjections into cerebral cortex and recording the resultant convulsive discharges in the EEG, the injection cannula serving as recording electrode. Very small quantities of the (+)-bicuculline methochloride produced sustained convulsive activity ('spiking') (2 μl of 0.5 mM solution in normal saline) whereas injection of 400 times this amount of the (−) form to the same animals (10 μl of 4 mM solution in normal saline) produced only transient convulsive activity.

More recently, experiments in the cat have shown that (+)-bicuculline methochloride will readily antagonise both GABA and synaptic inhibition in the cuneate nucleus, but that (−)-bicuculline methochloride does neither. Both isomers seemed to have little effect on depression of these neurones by glycine[11]. In comparison with other GABA antagonists that we have studied, (+)-bicuculline methochloride stands out for both it potency and its lack of effect on glycine (R. G. H. and M. A. Simmonds, in preparation).

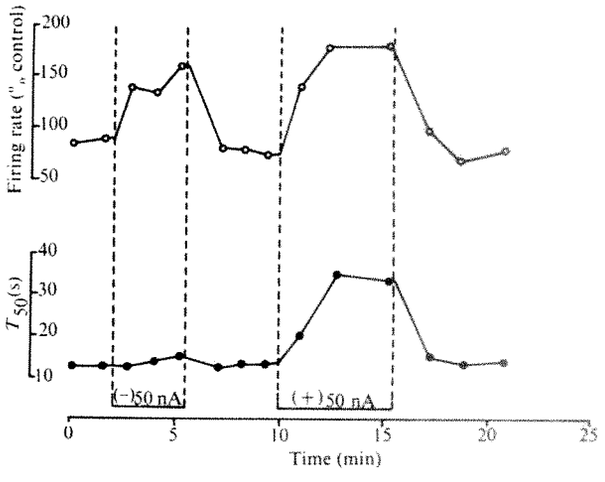

Fig. 1 Production of an increase in firing rate of a single cortical neurone by both (+) and (−)-bicuculline methochloride and GABA antagonism by the (+) isomer. The firing of this neurone was assisted with a continuous application of *d,l*-homocysteate 5 nA. Firing rate (○) immediately preceding each GABA application is plotted against elapsed time. The time taken to achieve 50% depression of firing (T_{50}) (●), by successive application of GABA 40 nA, measures the effectiveness of the GABA[9]. Each point represents one GABA application. Where shown by the first horizantal bar (−)-bicuculline methochloride 50 nA was applied and produced an increase in the firing rate, although it did not affect the response to GABA. The second horizontal bar represents an application of (+)-bicuculline methochloride 50 nA and this produced a similar increase in firing rate. Additionally the GABA T_{50} was much prolonged, indicating GABA antagonism had occurred. Both effects were readily reversible.

Thus, from these experiments, it would appear that only the (+) form of bicuculline methochloride is capable of antagonising both the depressant effects of GABA and presynaptic inhibition. Additionally, (+)-bicuculline methochloride is at least 400 times as potent a convulsant as (−)-bicuculline methochloride. It would, therefore, seem that the biological activity of these compounds is dependent on the absolute configuration around the asymmetric centres.

The GABA molecule is flexible and can exist in many different conformations. Attempts have been made[1,12,13], using molecular models, to explain the GABA antagonist action of bicuculline in terms of a stereochemical match with GABA. Blount and Gilardi have recently, independently determined the absolute configuration of bicuculline using X-ray analysis and Gilardi has pointed out that the previous model studies[1,12,13] on the preferred conformations for GABA and bicuculline were probably based on an incorrect configuration for bicuculline. Some workers[2,14–16] have suggested using molecular orbital and NMR calculations for protonated bicuculline and bicuculline methochloride in solution, as a way of determining the correct preferred conformations. Our results suggest that whatever the preferred conformations of bicuculline and bicuculline methochloride are found to be, the conformation of the (+) isomer will be more correctly isosteric with the preferred biologically active conformation of GABA than will the (−) enantiomer. This stereospecificity parallels that seen elsewhere in the nervous system, for example with muscarinic agonists of acetylcholine, narcotic analgesics and their antagonists and β-receptor blocking agents.

(+)-Bicuculline methochloride (Fig. 3) possesses the 1S, 9R configuration[17], whereas (−)-bicuculline methochloride (Fig. 3) has the 1R, 9S configuration[17], these configurations of course, being shared by the parent compounds (+) and (−)-bicuculline. These observations are compatible with the work of Johnston and his co-workers who revealed that corlumine (Fig. 3) is an effective GABA antagonist[8] for on examination of the stereochemistry we found that this substance also had the 1S, 9R configuration.

We are now examining the biological activity of bicuculline epimers and related compounds to determine whether the particular stereochemical arrangement involving a 1S, 9R configuration is the unique criterion for GABA antagonism in this series of alkaloids.

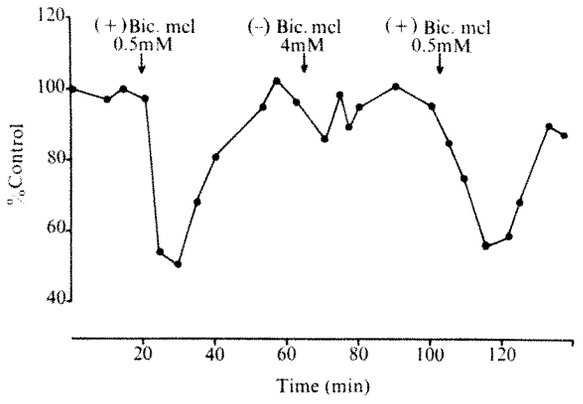

Fig. 2 Reduction of presynaptic inhibition in the rat cunate nucleus by (+)-bicuculline methochloride and the lack of effect of the (−) isomer. The inhibition was measured as the amplitude of the P wave (expressed as percentage of control) recorded in the cuneate in response to peripheral stimulation. At the first arrow (+)-bicuculline methochloride 0.5 mM solution in saline was applied to the surface of the medulla and rapidly reduced the P wave amplitude. After 40 min the P wave amplitude had returned to control values and application of 4 mM (−)-bicuculline methochloride solution at the second arrow had a negligible effect. A subsequent application of the (+) isomer (third arrow) again readily and reversibly depressed the P wave.

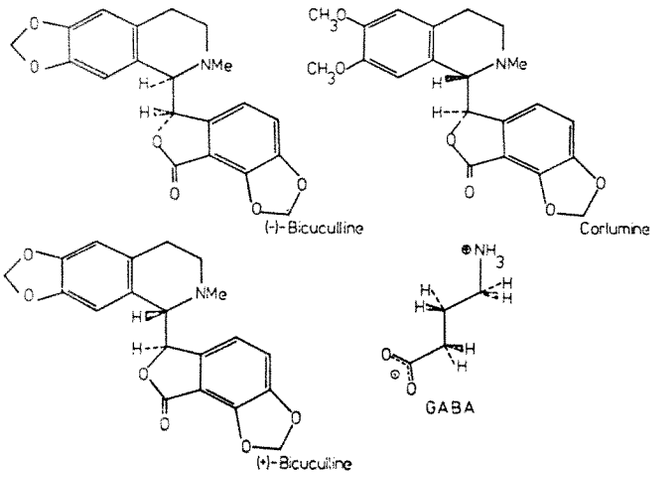

Fig. 3 Structural formulae showing the configurations of (+) and (−)-bicuculline and corlumine about their asymmetric centres. GABA is shown for comparison in one of its possible conformations. Although precise conformational information is not yet available, the preferred biologically active conformation of GABA is more likely to resemble the configurations of the isosteric groupings in (+)-bicuculline. Although the conformation of (+) and (−)-bicuculline methochloride will not be precisely that of (+) and (−) bicuculline due to steric effects of the extra methyl group[14,15], the configuration about the asymmetric centres will be identical.

During this work J.F.C. was the Sir Harry Jephcott Research Fellow and R.G.H. was supported by the bequest of W. L. Custance. We thank Celia Button for technical assistance and Professors D. W. Straughan and W. B. Whalley for laboratory facilities. This work was supported in part by a Medical Research Council programme grant to D.W.S.

Spin-lattice relaxation times of imidazole protons and their relevance to NMR studies of proteins

THE spin lattice relaxation time (T_1) is the exponential time constant for re-equilibration of nuclear spins with their surroundings (the lattice) following resonance excitation, and is consequently related to the correlation time of the nuclei in solution. Thus, the determination of T_1 values would be of interest in many biological systems. Measurement of the relative motility of different portions of a protein molecule, for example, could shed light on conformational and functional properties.

Recent technical innovations, notably the introduction of the Fourier transform (FT) technique in nuclear magnetic resonance (NMR) (ref. 1) have made determinations of T_1 almost routine. There are several reports of the measurement of T_1 values of imidazole C_2 protons of histidine residues in peptides and proteins[2-5], as well as applications of ^{13}C NMR (refs 6–11). Previous work has indicated the value of measuring the chemical shift of the imidazole proton resonances as a function of *p*H (ref. 12 and ref. 13 and refs therein). We now report the T_1 values of imidazole protons (Figs 1 and 2) as a function of *p*H.

The T_1 values of both the C_2 and $C_{4,5}$ protons of fresh solutions of imidazole (0.073 M) in 0.1 M sodium chloride in deuterium oxide, showed a minimum at about neutral *p*H (Fig. 3). Measurements made in the absence of (paramagnetic) oxygen by freeze-thawing five times under high vacuum then sealing the tubes, showed an even more pronounced minimum in the data (Fig. 3). Similar results were also observed for histidine, including degassed samples (Table 1). Increasing the salt concentration by a factor of ten in non-degassed samples of imidazole resulted in no significant change. The imidazole concentration was also decreased by a factor of ten and the absence of any change eliminated the possibility of intermolecular association as the origin of the *p*H dependence (Fig. 3).

Values measured in the presence of 10^{-4} M ethylenediamine tetra-acetate (EDTA) increased at neutral *p*H (Table 1 and Fig. 4). By contrast, the addition of 10^{-5}–10^{-6} M Cu^{2+} resulted in an expected lowering of the T_1 values of the ring protons at neutral *p*H, but had less effect in acidic or basic solution (Table 1 and Fig. 4). These results indicate that the phenomenon of the minimum in the *p*H dependence of the T_1 values of the imidazole protons arises from the binding of paramagnetic metal ion impurities in the samples at concentrations of 10^{-7} M or below. At low *p*H these ions would be displaced by deuterons and at high *p*H would bind more strongly to deuteroxide ions. The T_1 value of H_2O is reported to show no *p*H dependency[14,15]. (No significant *p*H dependence was observed for the T_1 value of HDO in the present work, even in the presence of 7×10^{-5} M Cu^{2+} ion, as expected[16].)

If the *p*H dependence of T_1 values were to be explained by a change in the correlation time (τ_c) of the imidazole ring at different *p*H values, this would require, for example, a fifteen-fold change in τ_c of the imidazole C_2 proton between *p*H 1.4 and 7.1 in the degassed samples. The viscosity of water is relatively insensitive to *p*H, and such a large change in τ_c is considered unlikely.

Table 1 Spin-lattice relaxation times (T_1) of imidazole protons

* Unless otherwise stated imidazole is 0.073 M in 0.1 M NaCl-D_2O. Most values for imidazole shown in this table are not given in Figs 3 and 4.
† At *p*H 7.1 the C2 and C4 proton lines are extremely broad in the presence of 7×10^{-5} M Cu^{2+}.

Estimates of the T_1 values for a nucleus can be made on the assumptions that only intramolecular dipole–dipole interactions are effective, and that rapid isotropic motion is occurring[1,2,5]. Since the C_4 and C_5 protons effectively relax each other, the T_1 values for these protons in acid *p*H are about half those of the C_2 proton. At neutrality, however, the ratio of the T_1 values is reversed (Table 1). This implies that the relaxation times are dominated by the paramagnetic ions present, and that these spend more time on average closer to the C_2 proton than the $C_{4,5}$ protons.

Calculations were made of the effect of protonation of the imidazole ring on the T_1 values[17] using the geometry determined by X-ray crystallography[18]. Results indicated only a small

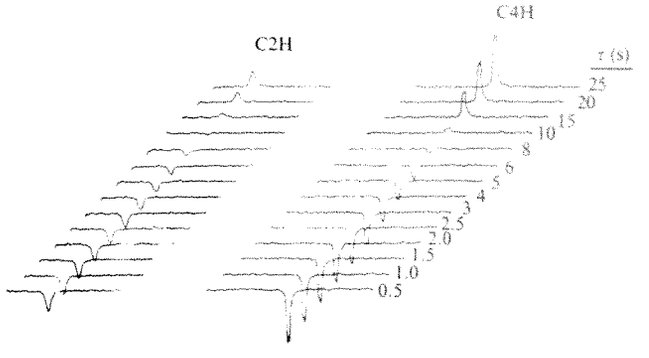

Fig. 1 Spectra of imidazole (0.073 M in 1.0 M NaCl, *p*H 2.0) at 220 MHz recorded on a Varian 220 FT spectrometer at 20 ± 1° C. A single (d, 180°, t, 90°) pulse sequence was used, where d is a delay time ($d > 5T_1$) and t is a variable time. At short values of t the spins are recorded as essentially inverted by the 180° pulse, while at long values of t they approach their maximum intensity value (I_∞). The T_1 values determined in this case were C_2H, 20.6 ± 0.30 s; $C_{4,5}H$, 17.6 ± 0.30 s. Values of *p*H are direct meter readings in D_2O (ref. 12).

change in the T_1 value of both the C_2 and $C_{4,5}$ protons would be expected on protonation of the ring assuming τ_c the same in both cases. This effect would probably be comparable with errors in the T_1 measurements. The increase observed in the T_1 values at low *p*H for the imidazole protons in histidine seems to have been mistakenly interpreted to indicate the titration of the ring[3], rather than the *p*H dependence of the binding of paramagnetic impurities.

Sodium chloride was used in these experiments to act as a reservoir of ionic strength to avoid change in this parameter when *p*H changes. Similar experiments with proteins would require a salt or buffer for reasons of solubility. Thus, the levels of impurity observed in these experiments are not above a reasonable value for practical applications of this technique. Analyses of highly purified imidazole grade III (Sigma) by atomic absorption gave 0.17×10^{-7} mg Cu^{2+} mg^{-1} imidazole or 0.12×10^{-8} M Cu^{2+}. The sodium chloride used in these experiments was Baker Analyzed reagent, with a specified heavy metal analysis including iron of 0.0002%. Analysis of the copper content in the standard 0.1 M NaCl–D_2O solution used gave a value of 2×10^{-5} mg Cu^{2+} ml^{-1}, corresponding to 8×10^{-8} M. Low temperature electron spin resonance (ESR) spectra of the solid NaCl and imidazole showed negligible amounts of paramagnetic material present. Further, the use of 1.0 M NaCl gave only a slight decrease in the T_1 values at neutral *p*H (Fig. 3) indicating that the extra NaCl did not provide a substantial increase in the level of paramagnetic impurity above the background range of approximately 10^{-7} M.

In view of the effects of degassing (Fig. 3) and EDTA (Fig. 4) separately on the T_1 values of the imidazole protons, experiments were performed by degassing in the presence of 10^{-4} M EDTA. As expected, T_1 values of the imidazole protons were increased, but there was still a minimum in the *p*H dependence (Fig. 4). This implies that the EDTA does not completely scavenge metal ions, allowing partial interaction with imidazole at neutral *p*H. Indeed there is evidence for the formation of a ternary copper-EDTA-imidazole complex[19], as for many other such combinations[20,21]. To test whether such a complex was being formed in our experiments, we reduced the ratio of concentrations of imidazole:EDTA by two orders of magnitude. If EDTA was

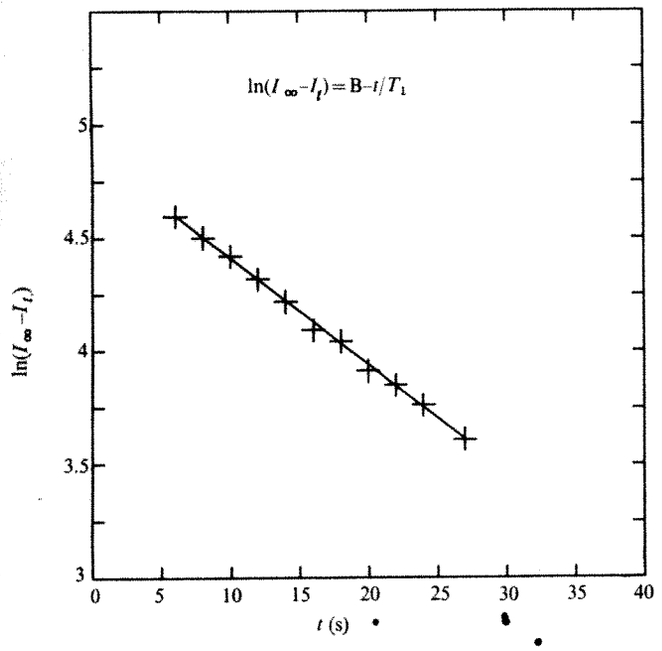

Fig. 2 Plot of the log of the intensity difference at time t ($I_\infty - I_t$) against t derived as in Fig. 1. The equation provides the best straight-line fit to the data, the slope of the line then gives the value of T_1. The value of the intercept B theoretically equals $\ln(2I_\infty)$. Imidazole *p*H = 3.43; $T_1 = 21.29 \pm 0.32$.

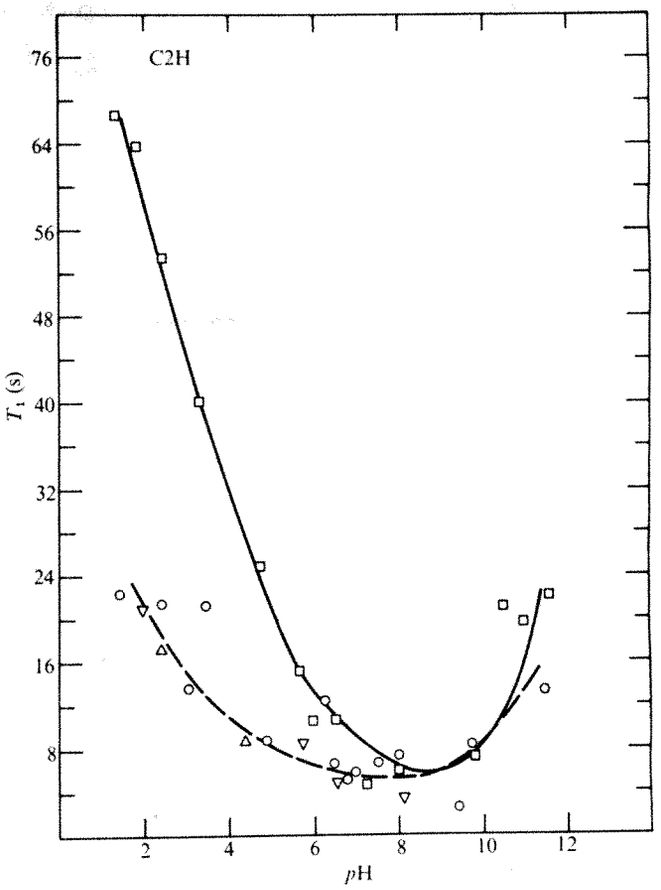

Fig. 3 Plot of the spin-lattice relaxation time (T_1) against *p*H for the C_2 proton of imidazole. Unless otherwise shown, all measurements were carried out in 0.1 M NaCl–D_2O in undegassed samples. The curves are hand-drawn indications of the *p*H dependence. The standard error in the T_1 determinations (Fig. 2) varied with the value obtained, for example, for the degassed samples for C_2H, *p*H 1.40, T_1 66.5 ± 0.7 s; 6.07, 10.6 ± 0.4 s; 10.50, 20.8 ± 0.6 s. □, Degassed; ○, Undegassed; △, diluted ten times; ▽, 1.0 M NaCl.

effectively scavenging metal ions the T_1 values of the imidazole protons would be expected to increase. But if a ternary complex was being formed, the T_1 values would be expected to decrease. In fact, a significant decrease in the T_1 values was observed for 7×10^{-3} M imidazole with 10^{-3} M EDTA (Table 1) in degassed samples, supporting the formation of a ternary complex.

The sensitivity of spin–spin relaxation times (T_2) of purine proton resonances to impurities of copper ion at concentrations of 10^{-6} to 10^{-5} M has recently been emphasised[22-24]. In the light of such considerations, T_2 evaluations from line width studies, particularly as a function of *p*H, must be treated with caution, except where the binding of paramagnetic ion well beyond the impurity level is being studied[25]. Calculations of T_2 from the line widths of the imidazole proton resonances in the presence of Cu^{2+} in this work show that $T_1 \approx 10\ T_2$. Thus, calculations based on the common assumption that $T_1 \approx T_2$ for such systems are probably in error. An increase in the line widths of imidazole proton resonances at intermediate *p*H values commonly observed may result at least in part from the *p*H dependence of the ion binding reported here, rather than the *p*H dependence of the protonation rate[26,27]. Thus, the interpretation of line widths of resonance in proteins in terms of structural effects[28] may be difficult.

T_1 values reported for the C_2 proton of imidazole residues in proteins have been interpreted to be due to the close approach of protons on other residues in the folded tertiary conformation of the native structure[2,3]. Due to the reciprocal relationship

$$(1/T_1)_{obs} = (1/T_1)_{intrinsic} + (1/T_1)_{para}$$

the effect of paramagnetic species would be expected to be greater on protons with intrinsically longer, rather than shorter,

Table 2 Spin-lattice relaxation times (T_1) of imidazole protons of histidine residues in several proteins

Protein	Histidine residues	Salt	*p*H	T_1 (s)
Hen egg white lysozyme	15	0.1 M NaCl	1.4	0.69 ± 0.02
		0.1 M NaCl	3.6	0.93 ± 0.03
		0.1 M NaCl	4.3	0.90 ± 0.03
		0.1 M NaCl	6.0	0.82 ± 0.06
Human lysozyme	78	0.1 M NaCl	3.0	2.65 ± 0.07
		0.1 M NaCl	4.5	2.41 ± 0.12
		0.1 M NaCl	6.0	1.33 ± 0.04
RNase A	105 (H-1)	0.1 M NaCl	1.7	0.88 ± 0.05
		0.1 M NaCl	3.4	1.02 ± 0.04
		0.1 M NaCl	6.0	1.07 ± 0.06
		0.2 M CD_3COONa	5.7	1.09 ± 0.02
		0.2 M CD_3COONa	5.5*	0.77 ± 0.03
	12 (H-2)	0.1 M NaCl	1.7	0.76 ± 0.02
		0.1 M NaCl	3.4	0.42 ± 0.02
		0.1 M NaCl	6.0	0.39 ± 0.04

		0.2 M CD_3COONa	5.7	1.14 ± 0.07
		0.2 M CD_3COONa	5.5*	0.51 ± 0.03

Values were calculated as shown in Fig 2. It is not easy to measure T_1 values of C_2 protons in proteins at *p*H > 6 due to the poor baseline from adjacent resonances. The four C_2 proton resonances in RNase A are resolved at only a few *p*H values. Assignments of the resonances (numbered H-1 to H-4 at *p*H 5.5) are taken from ref. 34.

* From ref. 2, determined at 100 MHz at 33° C.

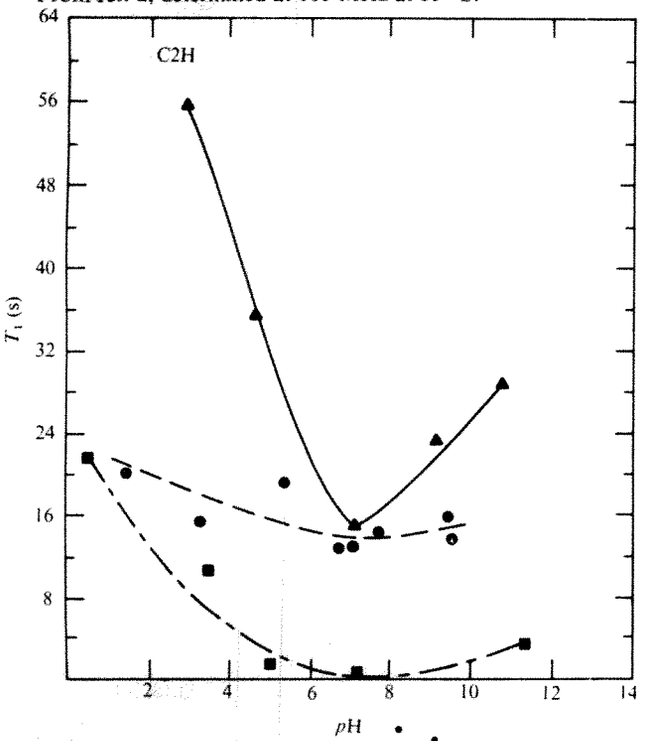

Fig. 4 Plot of the spin-lattice relaxation time (T_1) against p*H* for the C_2 proton of imidazole in the presence of EDTA and Cu^{2+} ion. ▲, EDTA 10^{-4}M degassed; ●, EDTA 10^{-4}M undegassed; ■, Cu^{2+} 7×10^{-6}M.

T_1 values. We have measured T_1 values of imidazole resonances in several proteins (Table 2), and have observed values as long as two seconds for the single histidine residue present in human lysozyme. Indeed, the *p*H dependence in this case showed an increase in acid *p*H similar to the phenomenon seen in imidazole itself. The values obtained for bovine pancreatic RNase A under essentially the same conditions were longer than those previously reported[3], as expected from the frequency dependence of T_1 values[1,5]. The T_1 values observed may reflect the environments of the histidine residues in the structure of RNase A (ref. 29). In view of the known binding of Cu^{2+} ion to these residues[30], however, and the phenomenon reported here for imidazole, such interpretations may not be justified.

The above considerations may not be as important for groups which do not bind metal ions. Nor would such a large effect be expected for the T_1 values of carbon nuclei observed by ^{13}C NMR. Other studies, however, have indicated the sensitivity of ^{13}C resonances to paramagnetic metal ions[31]. In view of the above, interpretations of regional unfolding on denaturation of proteins from relative values of T_1 (refs 3, 7, 8) must be viewed with some caution, and may also reflect local changes of ion binding on changing solution conditions and conformation. Addition of EDTA to protein solutions may not simply solve the problem of such measurements since EDTA binds to some proteins[32]. For many other proteins, there is a requirement for a metal ion[3,33], which although not itself paramagnetic may be accompanied by sufficient paramagnetic metal ion impurity to affect the T_1 values significantly.

We thank Edwin Becker, Philip T. Pitner and Regitze Vold for helpful discussions, Rolf Tschuden for implementing the Varian T_1 program, Charles Mueller for atomic absorption measurements, and Hideo Kon for help in running ESR spectra. R. W. thanks the National Research Council of Canada for financial support.

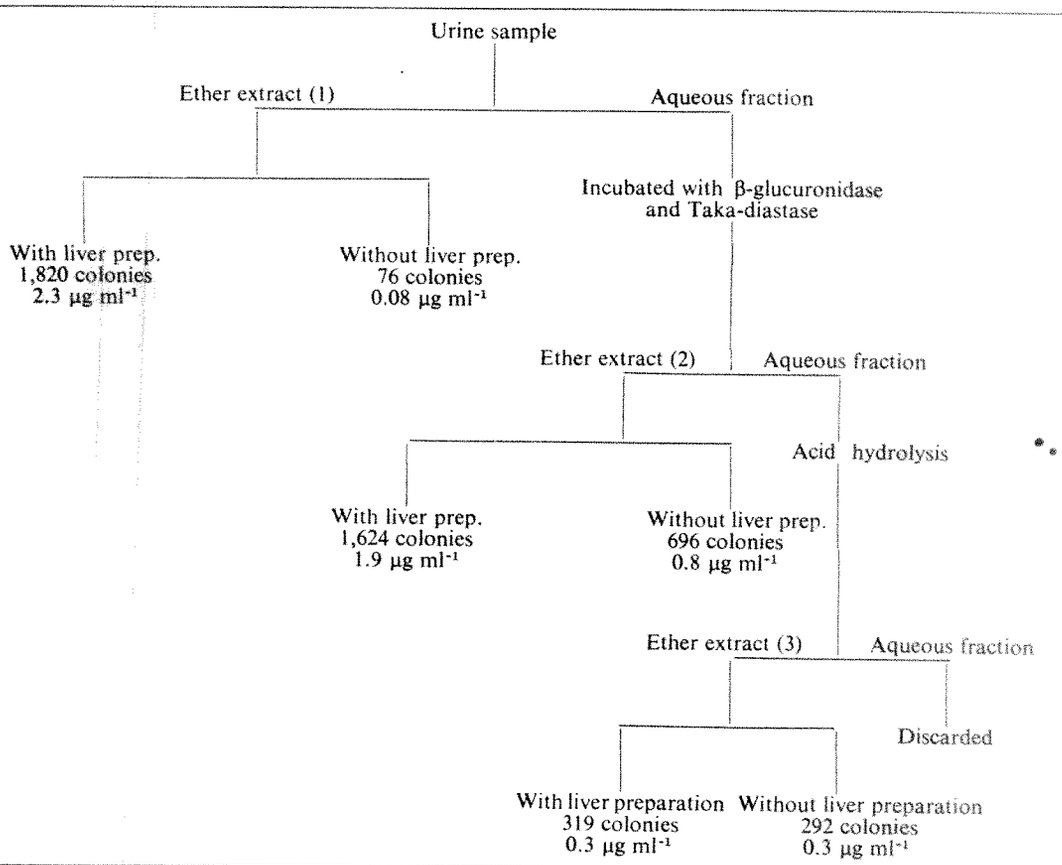
Detection of metabolic carcinogen intermediates in urine of carcinogen-fed rats by means of bacterial mutagenesis

SEVERAL developments suggest the possibility of a new means of assessing the exposure of human populations to chemical carcinogens. Carcinogens such as 2-acetylaminofluorene (AAF) and *p*–dimethylaminoazobenzene (DAB) have been shown[1-4] not to be carcinogenically active agents themselves, but to be converted into such agents by metabolic processes in the target organs (in these instances, liver). These studies also show that actively carcinogenic metabolites (as well as other metabolic products which are not carcinogenic) may be excreted in the urine, apparently as glucuronides[4,5]. Similar results have been obtained with human subjects ingesting aflatoxin B_1 from contaminated peanut butter[6].

Miller *et al.* showed that active AAF-intermediates are mutagenic in a test system involving *in vitro* interactions with transforming DNA followed by inoculation of the latter into a suitable strain of *B. subtilis*[1,7]. More recently Ames *et al.* have found that 18 of 20 chemical carcinogens that were studied are highly mutagenic toward *Salmonella typhimurium* test strains if they are incubated during exposure of the bacteria in a partially purified liver homogenate (a 9,000*g* supernatant)[8]. These observations considerably reduce the disparity between carcinogenicity and mutagenicity of organic compounds, which has until now discouraged the use of mutagenesis as a test for carcinogenicity. The technique developed by Ames *et al.* is simple, rapid, and sensitive (capable of detecting less than 1 μg of AAF) and hence well adapted to screening of environmental samples. We have investigated whether, in rats exposed to a carcinogen, metabolic intermediates of the latter can be detected in the urine by means of their mutagenic activity in the *Salmonella* test system.



Control male Holtzman rats were maintained on a balanced semisynthetic diet (see ref. 9 for details); experimental groups were maintained on the same diet supplemented with 0.67 mg g^{-1} of AAF or 0.6 mg g^{-1} of DAB. The animals were supplied with distilled drinking water *ad libitum*. At one week intervals after the onset of feeding, two rats from each group were placed in separate collecting

* Number of revertant colonies produced per plate by *Salmonella typhimurium* test strain TA 1538.
† These values are approximated from the calibration experiment, on the basis that 1 μg of AAF produces about 200 colonies. Corrections have been made for the number of colonies produced by urine samples from rats on the control diet.
‡ Urine concentrates were prepared by evaporating the urine to one-third the original volume.
§ In these instances the urine samples, after incubation with β-glucuronidase and Taka-diastase at *p*H 7, were extracted with ether. The ether extracts were evaporated to dryness and taken up in one-third the original volume (of urine) of DMSO and aliquots were tested against the bacteria.

Table 2 Analysis of mutagenic constituents of urine

21 ml of urine, adjusted to *p*H 7 and diluted to 75 ml with water was mixed with 60 ml of 0.1 M *p*H 7 phosphate buffer and extracted four times with 50 ml aliquots of ether (1). The aqueous phase, freed of ether, was incubated for 16 h at 37° C with 3,200 units each of bovine β-glucuronidase and Taka-diastase (Sigma). After cooling it was extracted four times with 50 ml aliquots of ether (2). The aqueous phase was adjusted to *p*H 1, refluxed 15 min, neutralised, and extracted four times with 50 ml aliquots of ether (3). The ether extracts (1), (2), and (3) were evaporated and residues dissolved in 2.6, 2.5 and 2.0 ml of DMSO respectively. 0.5 ml aliquots were used for each assay, which represented 4, 4.2 and 5.25 ml of urine for ether extracts 1, 2 and 3 respectively. The procedure is similar to that described in ref. 4. Actual colony counts per plate (test strain TA 1538) are given. Concentrations of mutagens are approximated as described in Table 1.

cages and urine samples were collected for 24 h. The samples were frozen until analysed, and sterilised by Millipore filtration before use.

Tests for mutagenicity were carried out according to the procedures developed by Ames *et al.*[8], using a strain of histidine-negative *S. typhimurium* (TA 1538) kindly supplied by Dr Ames. In this procedure, the sample to be tested is mixed with aliquots of a 9,000*g* supernatant prepared from a homogenate of normal rat liver, and with the bacterial inoculum incubated on an agar nutrient medium lacking histidine. Colonies that are formed in this medium represent reverse mutations of the original histidine-negative genome to histidine-positive. Counts of revertant colonies were made after 48 h of incubation at 37° C. All tests were made in duplicate; colony counts are reported as averages of the two values.

First we carried out a calibration experiment to determine the number of mutant colonies of *S. typhimurium* TA 1538 produced when a series of known amounts of AAF were incubated with the 9,000*g* supernatant. The results showed a linear response in the test range (0–50 μg of AAF, that is 0–0.2 mM concentrations of AAF in the final test solution) yielding about 200 colonies per μg of AAF with a blank value of 20 colonies in the absence of added AAF.

Table 1 shows that when rats are maintained on a normal diet for a 4 week period, weekly tests of urine samples show no significant variation in the number of revertant colonies produced either in the presence or absence of the liver preparation. AAF-fed rats excrete in their urine considerable concentrations of mutagenic substances. In the absence of liver preparation, the urine samples obtained in successive weeks, yielded respectively, 70, 93, 255 and 51 colonies per ml urine. These values are sufficiently above the control value (16 colonies per plate) to suggest the presence of intrinsically mutagenic substances in these urine samples. The evidence relative to the presence of activatable mutagens (that is those activated by exposure to the liver preparation) is unequivocal: in the presence of the liver preparation between 1,137 and 3,820 colonies per ml of urine are observed.

Also shown in Table 1 are the results of tests in which the urine samples were incubated with a mixture of β-glucuronidase and Taka-diastase. The incubation mixture was then extracted with ether, the extract evaporated to dryness, taken up in DMSO (dimethylsulphoxide) and tested in the usual way (see Table 2 for details of this procedure). As shown in Table 1, this procedure considerably increases the mutagenic activity of the samples, both in the presence and absence of the liver preparation. These data indicate that part of both the inherently active intermediates (that is, those which do not require activation by the liver preparation) and of carcinogen intermediates that become active only on treatment with the liver preparation occur in the urine as glucuronides.

DAB was one of the two carcinogens among the 20 tested by Ames *et al.*, which failed to yield mutagenic activity on incubation with the liver preparation. We also found (Table 1) that urine samples from DAB-fed rats tested directly by the Ames method show no mutagenic activity. But when tested according to the procedure (described above) for releasing intermediates from their conjugated forms, significant mutagenic activity is observed. Tested in this way

urine from DAB-fed rats produced 532 revertant colonies per ml of urine, in the presence of the 9,000*g* supernatant. Thus, DAB-fed rats excrete in their urine glucuronides of intermediates of the carcinogen that are mutagenically active in the presence of the liver preparation, following removal of the sugar residue.

By means of suitable extraction and incubation procedures, similar to those used by Weisburger *et al.*[4], it is possible to estimate the contribution of the several constituents to the overall mutagenicity of urine samples. The results of such an experiment, using urine from rats maintained on the AAF diet for 1 week, are shown in Table 2. In this experiment the following constituents were found in the urine sample, expressed in amounts equivalent to AAF: (1) activatable, unconjugated mutagen (probably AAF of faecal origin), 2.3 μg ml^{-1}; (2) intrinsically active, unconjugated intermediates, 0.08 μg ml^{-1} (an amount of marginal significance in this assay); (3) glucuronides of intrinsically active intermediates, 0.8 μg ml^{-1}; (4) glucuronides of activatable intermediates, 1.1 μg ml^{-1} (1.9–0.8); (5) acid-hydrolysable esters of intrinsically active intermediates, 0.3 μg ml^{-1}. Thus of a total about 4.5 μg ml^{-1} of carcinogen-derived material, 2.2 μg ml^{-1} is certainly of urinary origin and represents both inherently active and activatable intermediates of AAF. Since the mutagenic activity of the urine of DAB-fed rats becomes evident only after treatment with β-glucuronidase and Taka-diastase all of this activity must be due to glucuronides of urinary origin.

Thus metabolic intermediates of AAF and DAB can be detected in the urine of rats fed on diets that contain these carcinogens by means of tests based on mutagenicity towards a strain of *Salmonella typhimurium*, while the urine of rats on normal diets yield no significant response in these tests. This procedure should be applicable to the detection of exposure of human populations to carcinogens. Preliminary tests using human urine are in progress.

This work was supported by grants from the National Institutes of Health.

Note added in proof: After the completion of this work we learned that similar results have been obtained by Ames and Durston (*Proc. natn. Acad. Sci. U.S.A.*, **71**, 737; 1974).

Primary defect in copper transport underlies mottled mutants in the mouse

THE results presented here show that a primary defect in copper transport underlies the mottled syndrome in the mouse. The X-linked mottled mutants thus offer an excellent system for the study of mammalian copper metabolism. They also provide an animal model of the inherited human copper deficiency, Menkes kinky hair disease[1,2], which is also X-linked.

A number of different mutant alleles at the mottled locus are known and these are listed, together with their phenotypic effects, in Table 1. In all cases where the male hemizygote survives beyond birth, the resulting mouse shows a severe dilution in hair pigment (Fig. 1), although the individual hairs are pigmented at their tips, together with an altered hair structure[3] and curly whiskers. A persistent neurological disturbance is also apparent, consisting of a mild sustained tremor and general inactivity[4]. The more severe alleles *Mo* and *Mo^{dp}* die respectively *in utero* and at birth, and extensive skeletal defects have been reported in *Mo^{dp}* hemizygotes and heterozygotes[5].

Recent work[4] has demonstrated a severe deficiency in central noradrenaline (NA) levels in *Mo^{br}* and *Mo^{vbr}* males and this has been traced to a reduced *in vivo* conversion of dopamine to NA by the enzyme dopamine-beta-hydroxylase (DBH)[10]. A deficiency in NA was also found in mice hemizygous for the viable allele *Mo^{blo}* (Table 2). But direct *in vitro* estimates of DBH activity in *Mo^{br}* and *Mo^{blo}* brain tissue (Table 2) showed an elevated activity, in contrast to the *in vivo* situation. The DBH assay used[11] contains exogenous copper to inactivate endogenous inhibitors of the enzyme. Since DBH is a copper-containing enzyme with a cofactor requirement for cupric ion[12], the difference between the *in vivo* and *in vitro* results may reside in a copper deficiency in mutant brain tissue.

Estimates of liver and brain copper levels (Table 3) confirm the presence of a copper deficiency in *Mo^{br}*. The accumulation of copper in the intestinal wall indicates that uptake from the gut lumen is normal but that the general body deficiency arises from a defective transport within the intestinal epithelial or mucosal cells or across the membrane on the serosal aspect of these cells. To test this interpretation, the *in vitro* uptake of isotopic copper (^{64}Cu) into intestinal cells from *Mo^{br}* males and normal littermates was examined. Segments of intestinal wall were incubated in Krebs–phosphate buffer containing 1 mg ml^{-1} bovine serum albumin and 1 μg ml^{-1} $^{64}CuCl_2$ The results (expressed in ng $^{64}CuCl_2$ per 5 min per g $\pm$ s.e.m.) at 0°C (normal: 65.9 $\pm$ 11.9; *Mo^{br}*: 68.5 $\pm$ 11.5) and at 37°C (normal: 131.7 $\pm$ 27.4; *Mo^{br}*: 138.9 $\pm$ 27.7) confirm that the initial uptake into the intestinal epithelium is not defective.

Serum copper is largely contained in ceruloplasmin[15]. Ceruloplasmin levels were estimated by the method of

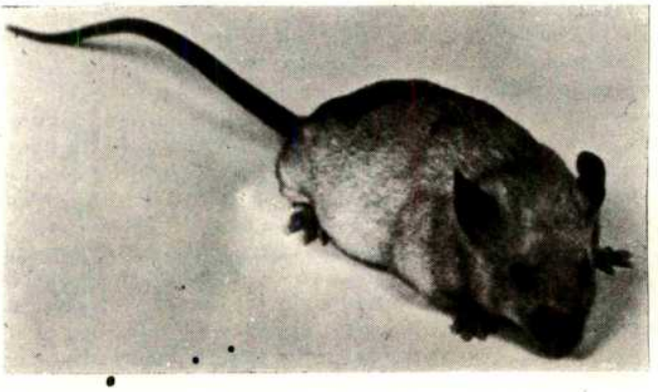

Fig. 1 A rare surviving *Mo^{br}* male.

Table 1 Phenotype characteristics of alleles at the X-linked mottled locus in the mouse

Allele	Male hemizygote	Female heterozygote	Ref
Blotchy (*Mo^{blo}*)	Pale fur, curly whiskers. Viable and fertile.	Variegated coat colour, curly whiskers. Viable and fertile.	6
Brindled (*Mo^{br}*)	Pale fur, curly whiskers. Dies at about 14 d *post partum*.	Variegated coat colour, curly whiskers. Viable and fertile.	7
Dappled (*Mo^{dp}*)	Pale fur, curly whiskers, skeletal defects. Dies at birth.	Variegated coat colour, curly whiskers, skeletal defects. Viable and fertile.	5
Mottled (*Mo*)	Lethal *in utero*.	Variegated coat colour, curly whiskers. Viable and fertile.	7, 9
Viable-brindled (*Mo^{vbr}*)	Pale fur, curly whiskers. Reduced viability and sterile.	Variegated coat colour, curly whiskers. Viable and fertile.	8

Ravin[13]. The results (normal: 6.52 ± 0.60; *Mo^{br}*: 4.33 ± 0.50 expressed in A_{530} units per h per ml serum $\pm$ s.e.m. show a significant reduction ($P = < 0.01$) in ceruloplasmin concentration in mutant mice. The precise function of ceruloplasmin is still obscure but it is unlikely that it represents a copper transport protein since the copper content of ceruloplasmin is not exchangeable *in vivo*[14]. Ceruloplasmin may function in the maintenance of a copper balance[15] and its reduced level in *Mo^{br}* supports this interpretation.

The experimental findings are consistent with a deficiency in copper transport and the relationship of a copper deficiency to the different pleiotropic effects of these mutants indicates that it is probably primary. The initial effect of a copper deficiency will be on the copper-requiring enzymes and the reduction in the *in vivo* activity of DBH has already been described. The elevated *in vitro* activity of this enzyme may be a reflection of an increased synthesis of the enzyme protein in response to the deficiency in NA biosynthesis. The neurological symptoms are consistent with a deficiency of NA[10], although a reduction in cytochrome oxidase, another copper-dependent enzyme, may contribute. The virtual absence of hair pigmentation can also be explained by a direct effect of the copper deficiency on the activity of tyrosinase, the first enzyme in the melanin biosynthetic pathway. The pigmented tip of each hair may arise from an initial but rapidly depleted copper store in the hair follicle.

Table 2 Brain noradrenaline and *in vitro* activity in *Mo^{br}* and *Mo^{blo}*♂♂ and normal (+) littermates

	Age (d)	NA	% difference from normal	DBH	% difference from normal
+	7	1.35 ± 0.19(6)†		33.14 ± 2.39(13)	
Mo^{br}	7	0.45 ± 0.10(6)†	−66.7*	48.81 ± 2.92(12)	+47.3*
+	28	1.96 ± 0.09(6)		33.02 ± 3.20(6)	
Mo^{blo}	28	1.34 ± 0.06(6)	−31.6*	77.63 ± 5.26(6)	+135.1*

DBH activity was assayed by the method of Molinoff *et al.*[11] with the following modifications. Brains were homogenised in 10 volumes of 0.005 M Tris-HCl buffer *p*H 6.0 containing 0.2% Triton-X100 and assays carried out using tyramine as substrate and a final concentration of 3.25×10^{-4} M $CuSO_4$. NA was assayed by the method of Anton and Sayre[22] as previously modified[10]. DBH activity is expressed as nmol octopamine g^{-1} h^{-1} $\pm$ s.e.m. and NA concentration is expressed in nmol g^{-1} $\pm$ s.e.m. Numbers in parentheses refer to number of mice used.

*Significance at the 1% probability level.

†Data previously published[4].

Table 3 Copper levels in brain, liver and intestinal wall from 7–10 d *Mo^{br}*♂♂ and normal (+) littermates

	+	*Mo^{br}*	% difference from normal
Brain	2.43 ± 0.27(7)	1.43 ± 0.24(7)	−41.1*
Liver	24.23 ± 1.98(6)	9.37 ± 1.14(6)	−61.3*
Intestinal wall	4.39 ± 0.87(12)	10.13 ± 1.84(12)	+131.3*

Tissue copper levels were estimated by the spectrophotometric method of Carter[23]. Tissue homogenates were hydrolysed with 2N HCl and precipitated with 22.6% trichloroacetic acid. After centrifugation, 0.5 ml of glacial acetic acid containing 40 µg dicyclopentamethylene thiuram disulphide was added to 1.0 ml of tissue supernatant and absorption determined after 10 min at 420 nm. Appropriate standards and blanks were carried through the procedure. Copper levels are expressed in µg g^{-1} $\pm$ s.e.m.

*Significance at the 1% probability level.

Numbers in parentheses refer to numbers of mice used.

Aortic aneurism arising from the fragmentation of the internal elastic lamina of the arterial wall has been reported in a number of mottled alleles[16] and it is significant that the formation of cross linkages between lysine residues in the synthesis of elastin and collagen is a copper-dependent process[17]. Recent results[19] indicate a reduced elastin cross linking in mottled mutants and the lysyl oxidase identified in chick bone collagen[18] seems a likely candidate for the action of the copper deficiency. The skeletal defects may similarly arise from a defective synthesis of bone collagen. The formation of disulphide bonds in keratin is also copper dependent, suggesting defective keratin synthesis as the basis of the curly whiskers and altered hair structure.

Copper deficiency has been shown[2] to underlie the human X-linked progressive brain disease, Menkes kinky hair disease[1]. The phenotypic effects of this mutant include abnormal white hair, altered hair structure[1], and arterial disease[2]. Copper levels are depressed in liver and serum, and the accumulation of copper in the intestinal epithelium[21] directly parallels that in the mottled syndrome in mice. Catecholamine biosynthesis has not been examined although the reported hypothermia[20] indicates that a deficiency in NA may be present.

Phenotypic variegation arising from random X inactivation[24] in a female heterozygote for an X-linked coat colour mutant depends on the cell autonomy of the mutant defect. The variegated appearance of the mottled heterozygote would therefore argue for the presence of the copper transport defect in the follicle and pigment cells of the skin, and possibly elsewhere. Copper-deficient cells would be expected to be at a selective disadvantage in competition with their normal counterparts, leading to a progressive dilution of mutant cells during development. The progressive darkening of *Mo^{br}* heterozygotes with age[3] supports this conclusion.

I thank Drs J. Axelrod and R. Ciaranello of the National Institute of Mental Health, Bethesda, Maryland, for a sample of purified phenylethanolamine-N-methyl-transferase for use in the DBH assay, and Miss K. McGillveray for technical assistance. The work was supported by a Project Grant from the Medical Research Council.

Uptake of radioactive DOPA by *M. leprae*

THE inability to culture *Mycobacterium leprae in vitro* has been a great obstacle to the progress of research in leprosy. This obstacle has been in part overcome by the introduction of the morphological index for the assessment of the viability of *M. leprae*, although the index is relatively crude. Biochemical studies[1,2] have revealed the specificity of the enzyme *o*-diphenoloxidase in relation to *M. leprae* as opposed to other bacteria included in the genus of mycobacteria. *o*-Diphenoloxidase oxidises 3,4-dihydroxyphenylalanine (DOPA) to quinone.

It seemed possible that DOPA might be a metabolite of the living bacilli and that radioactive atoms within the molecule would become incorporated into macromolecules within the living organism. We have shown this to be the case by high resolution autoradiography. Bacterial suspensions were prepared by the homogenisation of biopsies from untreated patients without disruption of bacilli and from patients in early stages of treatment, with a relatively high morphological index. Drops of suspension were added to a smear of warm agar on coverslips and incubated for various periods up to 48 h in the presence of 5 μCi ml^{-1} of ^{3}H-DOPA. The cultures were carefully washed and fixed in formol saline and then examined by autoradiography with Ilford K5 Emulsion as a thin film.

The high resolution obtained made it possible to observe the grains on individual bacilli (Fig. 1). A number of bacilli were clearly labelled after 48 h and some were intensely labelled; granular bacilli were unlabelled. The heavily labelled bacilli were often seen as a small centre of compact organisms within a large group. These clearly labelled bacilli might originate from centres of active growth within the population. In a parallel test with ^{3}H-thymidine a few of the bacilli in the aggregates showed grains. Labelled bacilli were also observed after uptake by mouse peritoneal macrophages in culture. Drutz and Cline[3] have observed labelling of some globi in human peripheral blood monocytes using thymidine. The high resolution autoradiography combined with the use of DOPA shown here enables the metabolic activity of individual bacilli to be assessed.

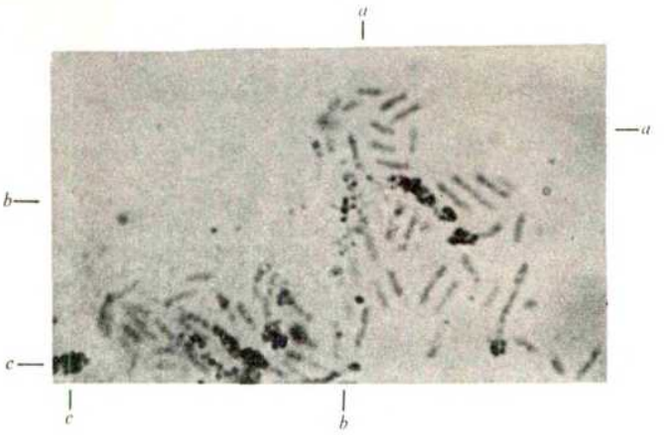

Fig. 1 Autoradiograph of *M. leprae* labelled with radioactive DOPA (5 μCi ml^{-1} for 48 h). Patient in initial stages of treatment. Light staining for acid-fast bacilli to show contrast with dense silver grains. *a*, Unlabelled bacilli; *b*, separate bacilli showing one to three grains; *c*, small groups of densely labelled bacilli.

By combining the use of labelled DOPA and labelled thymidine it therefore becomes possible to give, in addition to the morphological index, an assessment of metabolic activity (from DOPA labelling) and of rate of multiplication (from thymidine labelling) for individual bacilli of *M. leprae* in a given population. Such measurements can be made on biopsy specimens from new patients and also during treatment of patients as described above. It should also be possible to use the test for short term bacteriological investigations in the laboratory (somewhat similar to those used in the study of effects on metabolism and growth with organisms which grow well *in vitro*) for example to test the effects on metabolism and growth of potential chemotherapeutic agents, of immune serum and of lymphocytes. A more rapid method than autoradiography for assessing uptake of labelled metabolites is to use scintillation counting for bulk suspensions. Preliminary experiments measuring uptake of ^{3}H-thymidine by *M. leprae* by this method have also led to promising results.

These methods do not obviate the need for the use of mouse footpad experiments to assess the growth potential of *M. leprae in vivo*[4], particularly the use of immunologically deprived animals[5]. The most useful experimental approach in cell studies is generally to carry out parallel *in vivo* and *in vitro* investigations. The rapidity with which results can be obtained by the method described makes it attractive for a number of laboratory investigations.

We thank Mr Harold Das, Leprosy Home, Poladpur, for providing biopsy specimens from leprosy patients, and Drs Kamal Ranadive and C. V. Bapat for discussions. We thank Drs R. Tchao and D. Easty for advice in preparing the autoradiographs. This study was supported by the World Health Organisation and the Lady Tata Memorial Trust E. J. Reduced susceptibility to scrapie in mice after steroid administration

ANIMALS deficient in lymphoreticular function either by age, genotype or immunosuppression are more susceptible to infection by most known pathogens mainly on account of their depressed immunological responses. An intact lymphoreticular system (LRS), however, can itself contribute to disease by various mechanisms including; providing sites for multiplication[1], producing infectious complexes[2] and precipitating autoaggressive accompaniments and sequalae[3]. It is possible that a special class of this paradoxical relationship is exemplified by the slow encephalopathies of which the best understood is scrapie, others being kuru, Creutzfeldt-Jakob disease and mink encaphalopathy. In these diseases of the central nervous system, infection normally occurs by some peripheral route and there always seems to be an initial, probably obligatory, replicative phase in the LRS before gaining access to the target organ[4,5]. In spite of this involvement of the LRS, and indicating some very special relationship as its basis, there is a complete absence of conventional immunological responses. No scrapie-specific antibodies[6] or interferons[7] have been found, and this is not due to any generalised depression of immune reactions[8]. Immunosuppressive techniques, which severely impair the functions of the B and T-cell elements of the LRS, do not affect the pathogenesis of peripherally injected scrapie[9,10]. Also congruent with an absence of immune responses is the non-inflammatory nature of the brain lesions even in the later stages of the disease[11,12].

A number of findings, however, can be construed as indicating some positive relation between LRS function and the pathogenesis of scrapie agents. Apart from the early high titres of agent in these tissues[13], there is an increased incubation period in splenectomised[14] and spleenless mutant mice[15]; the unexpected finding of decreased susceptibility to extraneurally injected scrapie in newborn mice[16]; the demonstration that lymphocytes can become sensitised to scrapie-damaged tissue[17]; and the decreased levels of circulating polymorphonuclear neutrophils soon after scrapie infection[18,19].

In the light of these findings it is interesting to report that the pathogenesis of scrapie in young mice can be profoundly modified by early injections of the anti-inflammatory steroid prednisone acetate (PA). Injections of PA in physiologically high doses on the days immediately before and after an intraperitoneal (i.p.) injection of scrapie-infected brain homogenate results, unexpectedly, in prolonged incubation periods and a proportion of long term survivors using an agent dose which is 100% lethal in untreated controls (Figs 1 and 2). As the doses required for the effect rise rapidly with the age of the host, it is possible that the drug operates on the same tissues as those responsible for the reduced susceptibility of neonatal mice to scrapie[16].

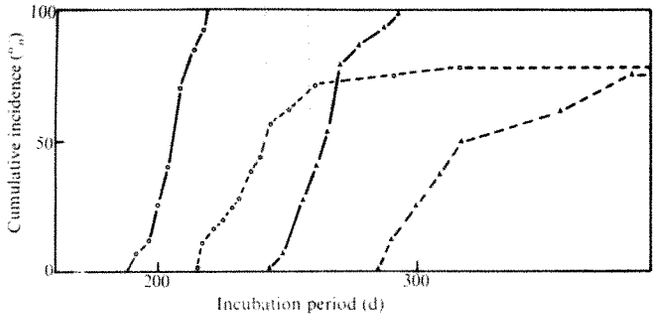

Fig. 1 Cumulative incubation periods for VL mice injected intraperitoneally (i.p.) as adults (21–42 d old) with 10% brain homogenate (500*g*, 10 min supernate) of 79A-strain scrapie agent (○) or 22C agent (▲); with (— — —) or without (———) the following high-dose prednisone acetate regime. Three days before the scrapie injection, 0.1 ml of a suspension of PA (250 mg kg^{-1}) in 2% Tween 20 in saline was injected subcutaneously (s.c.) over the shoulder, and then, beginning the day after the scrapie injection, 21 daily injections of PA suspension (15 mg kg^{-1}) were given s.c. as a maintenance dose. The controls received Tween 20 in saline only. The 0.02 ml injections of scrapie in saline contained approximately 1,000 i.p. LD_{50} infectious units.

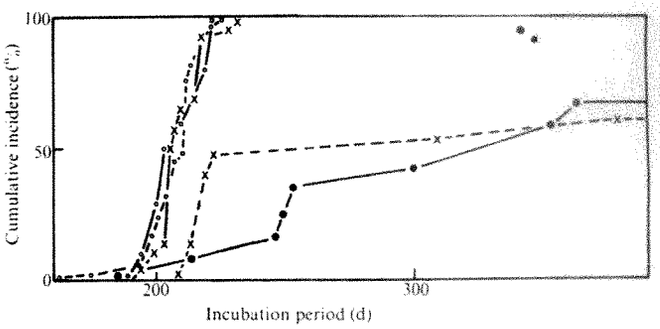

Fig. 2 Cumulative incubation periods for VL mice of different ages injected with 79A scrapie agent, together with (— — —) or without (———) a single moderate dose of PA. A similar 79A brain homogenate to that used in Fig. 1 was injected (i.p.) into mice aged 22–46 d (○), 14–20 d (×) or on the day of birth (●) (using due precautions against leakage). Half of the 22–46 and 14–20 d-old animals received a single s.c. injection of PA (50 mg kg^{-1}) in 2% Tween 20 in saline 3 d before the scrapie injection. No neonates were given PA treatment.

Figure 1 shows the effect on incubation periods of injecting adult VL mice with 79A or 22C scrapie, i.p., with or without a short, intensive course of PA injections at high dose levels during the first 3 weeks of infection. These steroid injections caused prolonged incubation periods, as judged by the onset of clinical disease seven months later, and a proportion (20%) of long term survivors, that is, individuals still alive and healthy more than 200 d after the death of all mice without steroid treatment. (In earlier pilot experiments some of these animals lived more than 700 d without contracting the disease although there were also some very late cases).

Figure 2 shows the effect of age and of a much lower dose of PA on the incubation period of 79A agent in VL mice of different ages between birth and 6 weeks. The single, previous injection of PA had no effect on the pathogenesis of the older animals (22–46 d at the time of scrapie injection), but it prolonged the incubation period of the younger age group (14–20 d) and caused 40% long term survivors. The cumulative incidence curve for this latter group is very similar to that for the neonatal mice which were injected at the same time and with the same dose of agent, but without a PA injection.

In spite of the fact that PA shares a number of immunosuppressive effects with thymectomy[9], and cyclophosphamide[10] and other drugs[20] it seems unlikely that these shared effects, particularly on B and T cells, are the basis of its influence

on scrapie incubation. It is not yet possible, however, to identify the relevant tissues or functions, which may indeed involve some that are not yet understood biologically[21]. Interim results from experiments to identify the relevant effects of PA show that: the kind of PA regime described seemed to have no effect on agent injected intracerebrally; there was no agent in the spleen of PA-treated mice surviving without signs to 340 d after scrapie injection; neonatal injections of PA did not affect scrapie susceptibility permanently (that is, by a developmental effect); and a variety of other PA regimes have been shown to be ineffective in modifying scrapie incubation periods (initial high dose without the maintenance course in adult mice); or high doses of PA either 6 weeks after i.p. injection of agent, or after the onset of clinical signs.

Before attempting to formulate detailed models based on these observations it will be necessary to be more specific about which tissues and cell types are involved. This will entail the use of other steroids and procedures, with different and more selective actions on various cell populations, together with a study of the dynamics of titre rise in those populations. We anticipate that macrophages, reticular cells, capillary sheath cells, polymorphonuclear neutrophils, mast cells, relatively steroid-resistant lymphocytes, various stem cells and sympathetic nerve terminals will yield the cell types involved. Sympathetic nerve terminals are not an obvious choice but they have several attractive features and have been discussed in connection with mink encephalopathy[22]. As a nervous, non-lymphoidal site of replication they would provide an explanation for the moderately high titres of agent found in organs such as the lungs, salivary glands and adrenals, and would permit the hypothesis that replication occurs in only one cell type instead of at least two. This hypothesis is more satisfactory in view of the fact that the onset of replication in both the periphery and the brain is controlled by the same gene[23], furthermore, the metabolism of sympathetic neurones can be modified by high doses of glucocorticosteroids[24]. This possibility would not, of course, exclude a role for lymphoidal elements in the uptake, accumulation and transportation of agent.

These findings carry the important experimental implication that attempts to encourage intraspecific passage of these 'slow viruses' by immunosuppressing the prospective hosts may be self-defeating[25]. As scrapie and other slow encephalopathies must infect by a peripheral route in the natural disease, a knowledge of the details of the early steps in their pathogensis—especially as these include some natural mode of inactivation—could be relevant for devising prophylactic treatments. Further investigation of this steroid effect could help to identify some of these early steps in infection and agent inactivation, and help to explain why the lymphoid system appears to act as a 'Trojan horse' instead of a defence mechanism in these diseases.

Absence of a pilus receptor for filamentous phage IKe

Plasmid-specific filamentous bacteriophages have been known to attach to the tips of certain pili present on the surface of their *Escherichia coli* or *Salmonella typhimurium* hosts; the synthesis of these appendages is determined by specific plasmids which reside in the host cell[1–4]. As well as providing receptor sites for such phages, these pili have been found to be essential for the conjugal transfer of the plasmids[5–7] and some hypotheses of

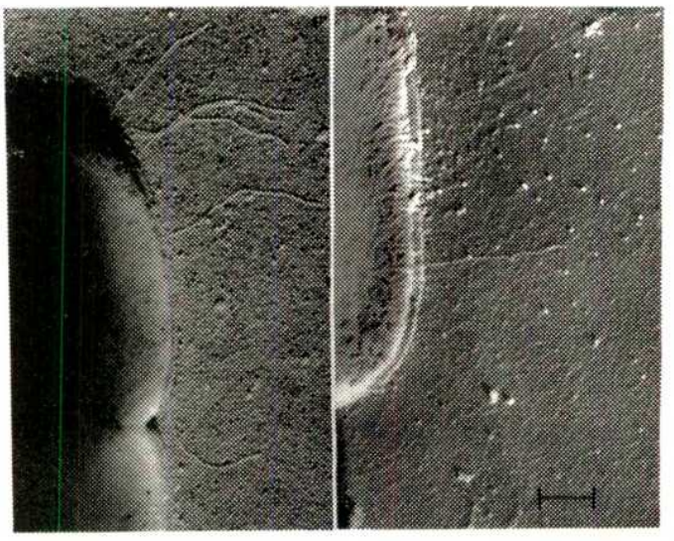

Fig. 1 The attachment of IKe particles to the surface of *E. coli* RM98$^+$ cells (× 81,600). The scale represents 100 nm.

* Phages were labelled with ^{3}H-thymidine. Phage/cell mixtures were layered on L broth containing 10% sucrose and centrifuged at 2,800 r.p.m. at 4° C for 25 min (ref. 12). The pellets were resuspended in L broth and 1 ml aliquots counted after mixing with 10 ml aquasol (New England Nuclear) in a Beckman LS-250 liquid scintillation system.

† The figures in this column have been corrected for background counts (30–40 c.p.m. ml^{-1}) obtained from counting 1 ml of the uninfected plasmid-bearing culture in 10 ml aquasol.

‡ Formalin-killed cells were washed free of formalin on sterile Millipore filters before resuspending in L broth and infecting with phage. Phage/cell mixtures were centrifuged following incubation for 10 min at 37° C and the supernatant assayed for unadsorbed phage on Hfr or RM98$^+$ indicator strains.

conjugal transfer consider that they are directly involved in the transfer process[6,8]. Previously, we have described a filamentous phage IKe, specific for the R factor RM98 and other R factors of the N compatibility group[9]. Here we describe evidence which indicates the direct attachment of IKe to the surface of its host which lacks an observable pilus-like appendage.

An *E. coli* F$^-$ auxotroph, strain JE2571, unable to synthesise common pili or flagella was used as a host for RM98. This host was capable of synthesising F- and I-type pili following the introduction into it of the plasmids F42 and a derepressed mutant of Col I transferred from *S. typhimurium* LT2 ColI drd. Strains bearing F42 or RM98 were grown to logarithmic phase in L broth[10]; the ColI$^+$ strain was cultivated in trypticase soy broth. These conditions yielded cells which always showed maximum adsorption of the respective phages. Drops of these cultures were placed on carbon-coated, formvar-supported 400 mesh copper grids. Dried grids were washed by touching the formvar surface of the grid to four drops of sterile distilled water. Shadowing was done at an angle of 11° with platinum–palladium or platinum–carbon in an Edwards High Vacuum Evaporator. The grids were examined in a Philips 300 electron microscope used at an accelerating voltage of 60 kV, at a main screen magnification of 14,000–35,000. The F42$^+$ and ColI$^+$ cultures showed their respective pili which were either surface attached or free. The RM98$^+$ strain showed neither surface attached nor free pili when we examined 10 grids prepared on three different occasions. We examined 1,300 isolated cells whose surfaces were clearly visible. At the magnification used, linear structures having a diameter of 5 nm or more should have been detected. Neither were any protrusions suggestive of very short pili observed.

In a second and independent approach, we assumed that if pilus-type appendages attached to the surface were present, they would be mechanically removable by agitating the cells. This treatment is known to detach F pili from the surface of F$^+$ cells[7,11].

L broth cultures of F42$^+$ or RM98$^+$ cells grown at 37° C to the logarithmic phase were chilled and treated with formalin (3.7% v/v) for 5 min. No viable cells could be recovered following this treatment which has been used to prevent the outgrowth of F pili following blending[11]. An aliquot of the formalin treated culture (40 ml) was blended at 0° C for 2 min at 10,000 r.p.m. in a 250 ml polypropylene bottle of a Sorvall Omnimixer to yield the 'blended' preparation (Table 1). Each cell preparation was infected with purified phage M13 or IKe; the phages were either labelled with ^{3}H-thymidine or unlabelled. Phage/cell mixtures were incubated at 37° C rather than at 0° C because IKe does not adsorb at the lower temperature.

The results in Table 1 indicate a reduction in the ability of blended F42$^+$ cells to adsorb M13. At high multiplicities of infection this reduction was 23–35% (Table 1, Experiments A and B) and 96% at low multiplicities of infection (Table 1, Experiment E) relative to unblended controls. Blended RM98$^+$ cells showed a two to three-fold increase in IKe adsorption; this was observed at high as well as low multiplicities of infection (Table 1, Experiments C, D and F). High speed blending of hosts bearing R factors of the N compatibility group has been reported to be ineffective in removing IKe receptors[13].

Table 2 Complex formation between IKe and RM98$^+$ cells at 37° C in L broth

Incubation (min)	% cells with attached IKe*	Numbers of IKe particles attached per cell 1	2	3	4 or more
0	0.4	0.2	0.2		
1	5.24	4.5	0.5	0.24	
2	16.9	15.3	1.6		
4	42.2	28.4	10.2	1.6	2.0
7	42.6	26.2	10.4	4.9	1.1
10	43.4	24.1	10.4	6.0	2.9

Phage/cell complexes were permitted to form at 37° C for 0–10 min in L broth and chilled immediately to prevent further adsorption. The complexes were separated from unadsorbed phage as described in the legend to Table 1. Pellets from the sucrose centrifugation were washed with chilled water and used for making grids which were shadowed.

* Three grids were prepared at each incubation time and at least 150 isolated cells examined per grid.

This evidence indicates the absence of a pilus-type receptor for IKe. It was therefore reasonable to expect that the phage would be seen to attach directly to the cell surface on which the receptor was located. This was in fact observed (Fig. 1) when complexes formed after mixing phage and cells were examined either immediately or following incubation of the mixtures at 37° C. The only difference noted was in the numbers of cells which showed attached phage particles (Table 2) but no difference could be seen in the manner of this attachment.

We conclude that a pilus-type receptor is not involved in the attachment of IKe to RM98$^+$ cells when the latter are grown in conditions which give a maximum specific susceptibility to

infection by IKe. We are now attempting to identify the location and nature of this receptor.

We thank Dr G. H. Haggis and Mr S. Itz for the use of electron microscope facilities at the Canada Department of Agriculture, Ottawa and Dr V. N. Iyer for editorial comments. This research was supported by a predoctoral trainee award to P. B. and an operating grant to R. I. from the Medical Research Council of Canada. *E. Coli* strain JE2571 was provided by Y. Nishimura and *S. typhimurium* LT2 Coll drd by G. G. Meynell.

Photophosphorylation of an ADP analogue by spinach chloroplasts

THE mechanism of ATP synthesis during photosynthetic phosphorylation is not yet known. It has been shown, however, that a coupling factor protein is necessary for coupling ATP synthesis to electron transport[1]. An interesting mechanism for photophosphorylation has been proposed[2,3] whereby photosynthetic formation of ATP is brought about by transphosphorylation of two coupling factor-bound ADP molecules to form AMP and ATP. The AMP would then be rephosphorylated in a step dependent on electron transport to form coupling factor-bound ADP which would act as the high energy intermediate (which has been thought to exist) to phosphorylate another ADP molecule to ATP.

We have used α,β-methhylene adenosine 5′-diphosphate (AOPCP), an analogue of ADP, to determine whether ADP undergoes transphosphorylation to AMP and ATP during photosynthetic ATP formation. Since the two phosphates in AOPCP are linked by a non-hydrolysable-methylene group[4], this ADP analogue cannot transfer its β phosphate in a myokinase type of reaction. Any photophosphorylation of AOPCP to α,β-methylene adenosine 5′-triphosphate (AOPCPOP) would therefore mean that photosynthetic formation of ATP is due to direct phosphorylation of ADP. Our results indicate direct phosphorylation of ADP to ATP.

Experiments in which AOPCP was used as substrate for the photophosphorylation reaction are shown in Table 1. Incubation mixtures containing AOPCP incorporated P_i into 'organic phosphate'. This reaction was light-dependent since no incorporation was obtained in the dark (experiment 1). The incorporation was not due to the presence of endogenous nucleotides since very little activity was found when AOPCP was omitted (experiment 2). Photosynthetic phosphorylation of AOPCP to AOPCPOP was catalysed at rates of 30 to 50 μmol AOPCPOP formed per h per mg chlorophyll. This reaction was six to ten times slower than phosphorylation of ADP. One of the reasons for the slower phosphorylation of AOPCP might be the differences in bond angles and distances of the P–CH_2–P and P–O–P groups[8], and so AOPCP may not fit into the active site for photophosphorylation as well as does ADP. The time course of photophosphorylation of AOPCP showed that the reaction was almost linear for 10 min, at which time more than 0.8 μmol of the total of 6 μmol of AOPCP in the incubation mixture was esterified with $^{32}P_i$.

To show conclusively that AOPCP was phosphorylated to AOPCPOP during photophosphorylation, the nucleotides from denatured incubation mixtures were separated by thin layer chromatography (Fig. 1). The reaction mixture incubated in the dark contained only AOPCP (spot 1), while the light incubated sample contained both AOPCP (spot 3) and AOPCPOP (spot 4). Radioactivity was found only in the AOPCPOP spot indicating that $^{32}P_i$ reacted with AOPCP to form AOPCPOP during photophosphorylation.

Table 1 Photophosphorylation of AOPCP by a spinach chloroplast preparation.

Nucleotide added	Illumination	P_i esterfied (μmol per h per mg chlorophyll)
Experiment 1		
AOPCP	No	0
AOPCP	Yes	47
Experiment 2		
None	Yes	0.4
ADP	Yes	299
AOPCP	Yes	31

One hundred grams of deveined spinach leaves were homogenised in 300 ml of 0.4 M sucrose containing 40 mM TES-NaOH and 0.2% fatty acid poor bovine serum albumin (Calbiochem) at *p*H 8 in a Waring blender. The homogenate was filtered through eight layers of cheesecloth and centrifuged for 5 min at 4,000*g*. The chloroplast pellet was resuspended in a solution containing 45 ml of the homogenisation medium and 15 ml of glycerol. Aliquots (1 ml) of the resulting suspension were stored in sealed vials in liquid nitrogen[5] and were thawed at room temperature immediately before use. Photophosphorylation was measured as described previously[6] using 2 mM ADP (Sigma) or AOPCP (Miles Laboratories) and 0.1 ml of chloroplast suspension (117 μg of chlorophyll). Incubation time was 5 min at 40,000 lux of incandescent light, or in the dark, as indicated. Chlorophyll was measured in 80% acetone extracts using the equation of MacKinney[7].

These results indicate that the ADP which serves as substrate in the photophosphorylation reaction is phosphorylated directly to ATP and does not undergo a transphosphorylation to AMP and ATP. Roy and Moudrianakis[2,3], Forti *et al.*[10] and McPhee and Brody[11], however, have obtained evidence for a transphosphorylation reaction. Moreover, both chloroplast[2] and mitochondrial[12,13] coupling factors have been found to bind adenosine nucleotides strongly. It is possible therefore, that the isolated chloroplasts contained coupling factor-bound ADP which underwent transphosphorylation to AMP and ATP and that the resultant coupling factor-bound ATP served as the 'high energy intermediate' for the phosphorylation of AOPCP. If this

were the case, our results would point to the existence of two separate ADP pools involved in photophosphorylation. One would be the substrate ADP (represented by AOPCP in our experiments) which would undergo direct phosphorylation to ATP. The other would be coupling factor-bound ADP which would act as a coenzyme for the coupling factor and which would undergo the transphosphorylation reaction proposed by Roy and Moudrianakis[2,3]. Figure 2 shows the reactions which might occur on the coupling factor; the proposed scheme is in agreement with our results as well as those of Roy and Moudrianakis[2,3]. It assumes that coenzyme ADP which undergoes the myokinase type of reaction stays bound to the coupling factor while the substrate ADP associates with the coupling factor only transitorily to accept the phosphate from coupling factor bound ATP produced by the myokinase-like reaction.

It has been observed[12] that the mitochondrial coupling factor contains two binding sites for nucleotides, one with high and one with low affinity for ADP. The low affinity site was identical with the active site for the ATPase reaction catalysed by the coupling factor. The function of the high affinity site is not known. Since the mitochondrial and chloroplast coupling factors are very similar, it is possible that the high affinity binding site is the site of the myokinase-like reaction involving the coupling factor-bound coenzyme ADP, while the low affinity site is the site of phosphorylation of substrate ADP. Reactions at the high affinity site should therefore have the properties ascribed to the formation of the 'high energy intermediate', while reactions at the low affinity site should be identical to those involving the last step in photosynthetic ATP formation.

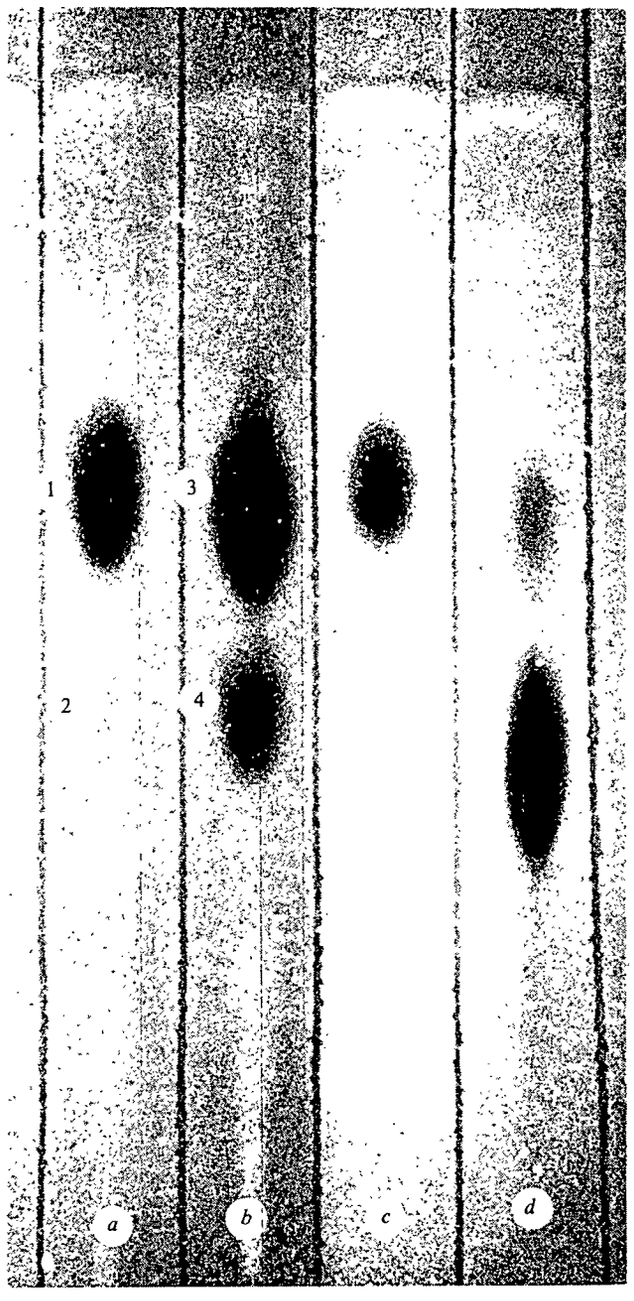

Fig. 1 Thin layer chromatography of nucleotide analogues. Chromatography was on cellulose coated Eastman Chromagram sheets using the solvent system isobutyric acid: concentrated ammonia: water = 66:1:33 (ref. 4). To remove salts which interfered with the separation, nucleotides from deproteinated incubation mixtures (3.2 ml) were adsorbed on 0.2 g of acid washed Norit charcoal. The charcoal was washed three times with 5 ml H_2O and nucleotides were eluted with 5 ml of 1% NH_3 in 60% ethanol[9]. The eluates were concentrated and aliquots used for chromatography. The resulting chromatograms were photographed under ultraviolet light with a Wratten 2A filter. Top and bottom correspond to front and start respectively. Chromatographed samples were: *a*, 10 min dark incubation; *b*, 10 min incubation at 40,000 lux; *c*, AOPCP standard; *d*, AOPCPOP standard. Analogue standards were purchased from Miles Laboratories. Numbered areas were scraped out and radioactivity of the material was counted in the liquid scintillation counter. The activities were: spot 1, 20 c.p.m.; 2, 17 c.p.m.; 3, 28 c.p.m.; 4, 1,278 c.p.m.

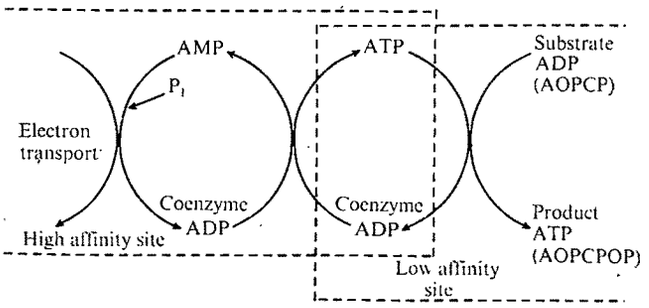

Fig. 2 Hypothetical scheme of reactions occurring on the coupling factor during photophosphorylation. The high affinity site is assumed to contain coupling factor bound nucleotides while the low affinity site is thought to be the site of phosphorylation of substrate ADP.

Sap stain in *Antiaris africana*, an economically important tropical white wood

MANY countries lose thousands of pounds annually through natural staining of valuable wood. Usually the organism which causes staining is the fungus *Botryodiplodia theobromae* Pat[1]. Field and laboratory experiments have shown that *Antiaris africana* becomes stained blue within 4 d of felling[2,3]. The fungus enters the cut surface of the wood through the vessels and within 2 d heavily colonises the surrounding vasicentric parenchyma cells. Infection of ray cells occurs through the vasicentric parenchyma cells[1]. The fungus has two types of hyphae: some are stout and brown in colour, others are thin and hyaline. The brown hyphae are predominantly found in vessels, tracheids and fibres (Fig. 1), whereas the parenchyma cells are heavily infected by the hyaline hyphae.

It is significant that not all fungi to which cut logs of *A. africana* are exposed gain entrance to the wood through vessels. *Phialophora fastigiata*, a sap stainer with a tendency to behave like a soft-rot fungus enters the wood through the ray parenchyma cells from which it ramifies into the vasicentric parenchyma cells. The vessels are infected through parenchyma cells. Within 14 d of infection, the fungus successfully digests the secondary wall of the fibres, creating cavities in oblique, transverse and longitudinal directions. *Rhinocladiella atrovirens*, a sap stainer, and *Chaetomium globosum* infect the wood through the rays and the vasicentric parenchyma cells.

Fig. 1 Brown hyphae in vessels of *Antiaris africana*. × 480.

Shoots of *A. africana* were exposed to $^{14}CO_2$ for 45 min three times a week for 2 weeks and then cut into small logs. The cut surface of each log was sprayed with spores of *B. theobromae* and the fungus was isolated from the logs after 7 d. The fungus was extracted with boiling ethanol and the ethanol-insoluble residue was wet-combusted[4]. Radioactivity was detected especially in the enthanol extract of the isolated fungus, providing direct evidence that *B. theobromae* uses food reserves of the xylem. There is also experimental evidence that there is no correlation between the severity of the blue-stain infection and the concentration of carbohydrate in the xylem[3]. It is, however, essential for carbohydrate to be present in the xylem for successful establishment of the fungus. Experiments on the food reserves of the xylem of *A. africana*[5] show that it is rich in various carbohydrates. Kozlowski and Keller[6] have reported that carbohydrates are stored in the living parenchyma cells of the xylem of trees. It is, therefore, most probable that the hyaline hyphae predominantly found in the living parenchyma cells of the wood of *A. africana* are nutritional in function.

Several methods have been suggested for the control of sap blue stain fungi[2,7,8]. Eight antitranspirants have recently been tried in the laboratory on germination of spores of *B. theobromae*, and in the field on the control of blue stain in *A. africana*, and four have been very effective. Spores were mounted in various concentrations of antitranspirants and incubated at 100% relative humidity. Percentage germination was counted over a period of 24 h. In the field experiments conducted during the rainy season when the incidence of blue-stain in *A. africana* is known to be heaviest[2], cut surfaces of logs were dipped in antitranspirants. Needle Fast, Spruce Seal and Vapor Gard (1–5%) Wilt Pruf (5–25%) prevented spore germination and significantly reduced blue stain infection of wood left in the forest for 4 weeks. Each of the four antitranspirants significantly reduced water loss from the cut surfaces of the logs. There was no infection when the water content of the wood was more than 50%.

These observations indicate that successful control of blue stain of wood should be aimed at either depleting the food reserves in the wood or using chemicals that will prevent rapid water loss from cut surfaces of logs.

I am grateful to Dr J. F. Levy of Imperial College of Science and Technology, London who supplied me with *R. atrovirens*, *C. globosum* and *P. fastigiata*.

matters arising

Spotted centromeres in human chromosomes

SIR,—The demonstration by Eiberg[1] of equal sized Giemsa-stained paired dots in the centromeric regions of human chromosomes, raises the question of whether these dots are equivalent to, or associated with, the paired spheres, or dots, observed in these regions in chromosomes preparations handled in different ways.

Sharply delineated pairs of unstained spheres associated with the centromere are often to be seen in human, mouse and other mammalian chromosome preparations of cells pretreated with colcemid and stained with orcein, or Giemsa, in the conventional way. These spheres stand out more clearly in cells with cytoplasmic staining and they have the appearance of unstained vacuoles (Fig. 1*a*). Dots, perhaps more closely similar to those described by Eiberg[1], are also to be seen in optically shadowed, but unstained, human chromosomes[2] that have been exposed to the alkali and saline pretreatments necessary before Giemsa staining in a technique[3] to give C-banded chromosomes, or to a trypsin schedule[4] to give G banding. These dots appear as raised prominences in the centromere regions of the collapsed chromosomes and are similar in size and position in all members of the chromosome complement (Fig. 1*b* and c). They cannot be simply equated to the densely stained Giemsa C bands, as the size of the centromerically located C bands differs between chromosomes and indeed some C bands are very large (such as those of chromosomes 1, 9 and 16) and are not confined in their location to the centromere regions as, for example, in the Y chromosome. Differences between C bands and a more localised centromeric staining have also been noted by Voiculescu *et al.*[5] in banded preparations of hamster chromosomes. The smaller centromeric C bands in the human complement (Fig. 1*d*), however, cannot be distinguished from the unstained promontories seen in these chromosomes in shadowed, but unstained, preparations.

The regions in which these stained, or unstained, dots appear are known to contain the paired disk-shaped kinetochores that are located in the centromere region on opposite sides of sister chromatids and which are clearly visible using the electron microscope[6]. Such studies have also shown that the paired fibrillar elements of the kinetochore have associated with them a less dense granular matrix which is also fibrillar in nature and which does not completely encircle the centromeric regions of the chromatids[7]. Moreover, although colcemid inhibits the full development of the spindle, the centromerically located spindle tubules are always present so that spindle proteins are concentrated in these regions and attached to the chromosome[8]. It would seem to us therefore that the stained, or unstained, dots which are seen under the light microscope to be specifically located in the centromere regions, may represent the kinetochores and particularly their associated proteins.

It is perhaps worth noting that although in man[9–11] and mouse[12] C band material is confined to the centromere regions in the autosomes, in cultured cell lines these materials are sometimes translocated away from the centromere. Thus, even in these materials, C banding does not provide a reliable method for detecting centromeres. On the other hand, a simple centromere staining method, such as Eiberg's, would, if consistent, provide a good method for locating centromeres and a useful tool in resolving the centromere states of D/D, D/G and G/G chromosome translocations in man and in screening for dicentric chromosomes in irradiated cells.

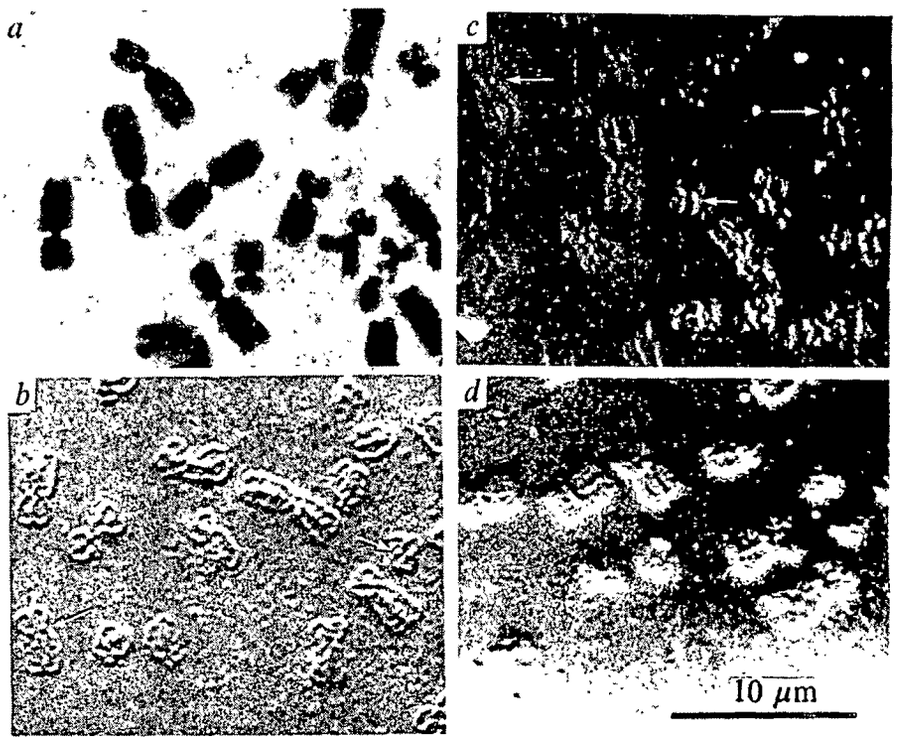

Fig. 1*a*, Human chromosomes stained with lactic-orcein and showing the pairs of unstained dots associated with the centromere. *b*, Unstained optically shadowed human chromosomes treated with trypsin as in Seabright's[4] G banding technique. Note the paired dots at the centromeres. *c*, Unstained and shadowed chromosomes treated with HCl, saline and $Ba(OH)_2$ as for C banding[3]. Note the paired dots at the centromeres. *d*, Shadowed chromosomes that have been stained for C banding. Compare the prominence at the centromere with *b* and *c*.

Random deviations or asynchronous DNA synthesis?

SIR,—In a study concerning the labelling of the X chromosomes of heterozygous Dp(1;f) AM female larvae, Bender, Barr and Ostrowski[1] compared the absolute amount of silver grains distributed over the 1AB region of the paired X chromosomes (compound X) with the absolute amount of labelling over the homologous region of the free duplication (fragment). In all 97 spot-labelled nuclei analysed, the 1AB region of the fragment and the compound X were asynapsed. In 65 of these nuclei a maximum of only two silver grains could be found over each of the two 1AB regions. The authors deemed this amount of labelling as unsignificant. Of the remaining 32 nuclei, 22 showed significant labelling over the compound X but an unsignificant labelling over the fragment. In contrast, only five nuclei indicated significant labelling over the fragment but unsignificant labelling over the compound X. In the remaining five nuclei, significant labelling was found both in the fragment and in compound X as well.

From these results the authors concluded that the fragment does not replicate the DNA in synchrony with the homologous region of the compound X chromosome. This conclusion is based on two assumptions. First, that labelling of less than a tight cluster of three silver grains over a given chromosome region is unsignificant and, second, that a synchronous DNA synthesis must be reflected by a constant ratio in the amount of silver grains of the two homologous chromosome sections without any random deviations.

On the basis of experiences with autoradiographic studies (ref. 2, and our unpublished results), we wish to mention that there is still another interpretation for these data. During the preparation of our manuscript, similar judgements have been published[3].

The data published in Fig. 1 of ref. 1 are repeated here, but are tabulated in a different way (Fig. 1 and Table 1). It is noteworthy that only seven (Fig. 1) of 97 nuclei show relatively strong deviations (more than three silver grains) from the axis of synchrony. In three of these cases the fragment synthesises its DNA earlier and in the remaining four later, than the compound X. Eleven nuclei show only one silver grain in compound X and none in the fragment. The remaining 49 labelled nuclei (including the seven exceptions) are distributed with 23 on each side of the axis of synchrony and three nuclei matching the axis of synchrony directly.

In light of the observation that of 97 nuclei with 194 1AB regions, 113 were unlabelled and the remaining 81 were distributed according to Table 1, it seems to be inconsequential, in our opinion to eliminate 44 cases of less than three silver grains as background labelling: in particular, because the authors claim that background labelling of the autoradiograms analysed was very low. Recent (unpublished) studies have shown that the restriction in the significance of labelling in respect to a tight cluster of three silver grains must be handled with caution, if slides with a very low background are used.

The authors' assumption, that the silver grains in the two corresponding 1AB regions have to indicate a constant 2:1 ratio according to their DNA amounts (or somewhat less than 2:1, because of the greater self absorption in the compound X), is based on the studies by Plaut and Nash[4]. During (an unpublished) reinvestigation of this problem, however, one of us (K. H.) has shown that the labelling in homologous bands of normally structured asynapsed chromosomes showed only a high degree of correspondence and not the absolute correspondence of Plaut and Nash[4]. Random deviations were to be found with common frequencies (Fig. 1). It must also be mentioned that 6.8–28.8% of 'exceptional patterns' are to be found in all phases of the replication cycle of normally structured chromosomes in *Drosophila melanogaster*[5–7]. Therefore, the seven nuclei with strong deviations (Fig. 1) may belong to those exceptional deviations. Also, on the basis of the arguments presented, we believe that the replication of the duplicated chromosomal region should better be interpreted as synchronous DNA synthesis.

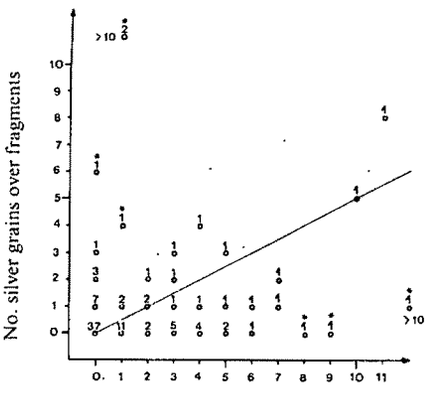

Fig. 1 Deviations of labelling intensity over the two 1AB regions in 97 salivary gland nuclei of Dp(1;f)AM female larvae, according to the data of ref. 1. The position of each circle indicates the absolute number of silver grains over the 1AB regions of the duplication (fragment) observed, as well as over the 1AB region of the two paired X chromosomes (compound X). An axis of synchrony is drawn through those circles which show a 2:1 ratio for the amount of silver grains. Figures on top of each circle indicate the number of cases observed. *Nuclei with strong deviations of labelling.

Table 1 Number and distribution of silver grains observed over each of the two 1AB regions in 97 nuclei of Dp(1;f)AM female larvae (changed after Bender, Barr and Ostrowski[1])

No. of silver grains observed over the 1AB regions	>10	11	10	9	8	7	6	5	4	3	2	1	0
Distribution of 1AB regions observed	3	1	1	1	2	2	3	5	8	11	11	33	113

Magnetic insulation

SIR,—The extravagant claims presented in a recent article by Winterberg[1], led me to look into the background of the idea of 'magnetic insulation'. The purpose of this letter is to point out that the scheme described in that article is unsound and will not work.

The basic idea in Winterberg's article is the prevention of electrical breakdown between conductors at different potentials using the interposition of a combination of a high vacuum and a high magnetic field parallel to the conductor faces. Electrons which could initiate the breakdown are supposed to be returned by the magnetic field to the electrode from which they were emitted. This, however, is essentially the configuration found in any number of magnetron devices. In forty years of experiments in this field it has been shown time and again that complete cutoff is not achieved for any magnetic field. The reason is that collective effects intervene; space charge instabilities always result in some current passing between the electrodes. Under these conditions simple orbit calculations no longer apply.

Winterberg's ideas were presented earlier in a longer article[2]. In that article he suggested that 'magnetic insulation' might make possible a transformer for 10^9 V. A year later the same objections that I have raised were published in some detail by Hirsch[3]. He concluded "The cutoff anomaly therefore renders 'magnetic insulation' impracticable . . . Clearly, the only way in which vacuum breakdown due to field emission from a given surface can be avoided is by reduction of the surface electric field." A reply by Winterberg[4] completely failed to answer Hirsch's objections.

Perhaps claimants for 'magnetic insulation' could be given the same requirement that is presented to inventors of perpetual motion machines. They are usually instructed to accompany their claims with a working model.

Yours faithfully,
JOHN P. BLEWETT

Brookhaven National Laboratory,
Upton, New York

[1] Winterberg, F., *Nature*, **246**, 299 (1973).
[2] Winterberg, F., *Rev. scient. Instrum.*, **41**, 1756 (1970).
[3] Hirsch, E. H., *Rev. scient. Instrum.*, **42**, 1371 (1971).
[4] Winterberg, F., *Rev. scient. Instrum.*, **43**, 814 (1972).

DR WINTERBERG REPLIES: Contrary to Blewett's belief, magnetic insulation has not only been experimentally confirmed[2] since I proposed it several years ago[1], but is already utilised in the coaxial transmission lines of relativistic electron beam generators (for example, the MJ Aurora machine). The magnetic field needed for the insulation effect in this case is generated by the strong azimuthal self-induced field of the current pulse passing through the transmission line. In the Aurora machine for example, the pulse length is 100 ns and the feasibility of magnetic insulation is therefore confirmed, at least for this time scale. The same should therefore be true for the magnetically insulated high voltage transformer[3], at least for an a.c. frequency of the order 10 MHz as it is realised in a Tesla transformer.

Blewett argues that experience with magnetron devices speaks against the feasibility of magnetic insulation and that the device described in my article falls into the same category. This, however, is not quite correct, because the magnetron device is an open ended system. It therefore has quite similar end losses and instabilities as an open ended plasma confinement device. This contrasts with a closed toroidal system, which is proposed in my article. In a magnetron the electrons can drift freely in the axial direction, causing breakdown at the ends, by contrast with the proposed closed toroidal system in which this free motion follows a closed loop parallel to the circular torus axis.

Both the magnetically insulated coaxial transmission line and the high voltage transformer are also open ended systems but with an azimuthal field, rather than an axial field as in the magnetron. The azimuthal field leads to a much smaller axial drift motion than in the magnetron device. Here again, the analogy with the z pinch (azimuthal field) and the θ pinch (axial field) can be drawn. Therefore, for both the magnetically insulated coaxial transmission line and the high voltage transformer, larger time scales than in the magnetron can be expected. This prevents breakdown. A closed toroidal system, as it is proposed in my article should, however, lead to substantially larger breakdown times, quite analogous to the much longer plasma confinement times for closed than for open ended systems. It is also known, from toroidal plasma confinement devices, that even higher stability can be achieved by strong shearing of the magnetic field lines and average minimum B, as in the Stellarator or Tokamak. The same principle could, of course, be used in the proposed machine, a big shear field being produced with the external field coil, with an induced circular current in the central conductor or with a combination of both. In a closed, magnetically insulated system the only important collective instability which then remains is the diocotron instability which is suppressed by making $\omega_p^2 \ll 2\omega_c^2$ where ω_p is the electron plasma frequency and ω_c the electron cyclotron frequency. This is one of the conditions for magnetic insulation.

Bovine thymin

SIR,—Recently, Goldstein[1] reported on the isolation of two polypeptide hormones from bovine thymus. He suggests and extensively uses the terms thymin I and thymin II to designate these hormones.

The choice of these names seems unfortunate because of a possible confusion with thymine (2,4-dihydroxy-5-methyl-pyrimidine), a component of some nucleic acids. In French and German, there would be only one way of writing both thymine and thymin, so that they could not be distinguished from each other. The numbers I and II should also be considered as provisional ones, as the structures of the hormones are still unknown and it could be that II is the precursor of I.

It is to be expected that any new important biochemical compound will ultimately have its name defined on an international basis by a nomenclature commission of such a body as the International Union of Biochemistry (IUB) or the International Union of Pure and Applied Chemistry (IUPAC). As this is likely to take some time, it would be worthwhile if Dr Goldstein could reconsider the question of the names to be used for the new hormones, to make them unambiguous and compatible with existing recommendations.

Yours faithfully,
M. ROTH

Central Laboratory,
Hôpital Cantonal,
Geneva, Switzerland

[1] Goldstein, G., *Nature*, **247**, 11 (1974).

DR GOLDSTEIN REPLIES: The points made by Dr Roth are well taken. The name thymin was originally assigned[1] to designate a hormone of the thymus

by the traditional '-in' suffix (as for insulin and renin). At that time we avoided naming the hormone by its action as we were uncertain whether the neuromuscular effect was physiological; indeed, it now does not seem to be so.

Unfortunately, there is confusion between the polypeptide hormone thymin and the base thymine, which was also named for its original isolation from thymus. Would the name thymopoietin be more acceptable? This would indicate the action of the hormone in inducing stem cell differentiation to, or 'producing', thymocytes (as in erythropoietin and granulopoietin).

I agree that the numbers I and II are provisional and that this will be resolved by structural work, which is in progress.

(Na + K)-ATPase activity in cattle red cells

SIR,—Schatzmann[1] has described a positive correlation between ouabain-sensitive ATPase activity and red cell K levels in cattle, cells with higher K levels giving a greater enzyme activity. These determinations were made with Na=150 mM, K=10mM. If ouabain-sensitive ATPase is determined as a function of K concentration (at K levels >5 mM to saturate the outside pump site) in fragmented red cell ghosts from individual cattle with different erythrocyte K levels, it can be seen that, as in other ruminant red cells[2], the enzyme shows a variable degree of K inhibition (Fig. 1). Thus, membranes derived from cells having an original K level of 26 mmol per 1 cells are 50% inhibited at K=20 mM, whereas membranes from cells originally having 77 mmol K per l cells are not 50% inhibited even at K=100 mM. From the 26 cows so far investigated a continuous spectrum of K sensitivities has been found, with the degree of K inhibition correlating well with the resting K level of the original red cells. It therefore seems likely that the internal affinity for K of the ouabain-sensitive ATPase in cattle red cells may be the dominant determinant of resting cell K levels, and not the amount of enzyme activity measured at relatively low K concentrations.

Yours faithfully,

J. C. ELLORY

ARC Institute of Animal Physiology, Babraham, Cambridge CB2 4AT, UK

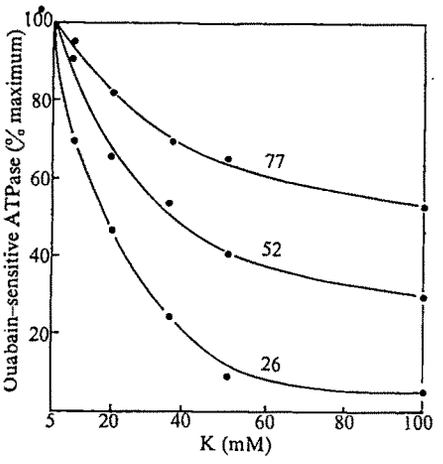

Fig. 1 Ouabain-sensitive ATPase activity in cattle red cell ghosts as a function of K concentration. Ghosts prepared and assayed as previously described[3]. Incubation conditions: NaCl 150 mM, $MgCl_2$ 1.25 mM, Na_4-ATP 1.25 mM, 10 mM Tris *p*H 7.7 at 37° C, (KCl + choline Cl) 100 mM, ouabain, when present, 0.1 mM. Ghost concentration equivalent to 25% haematocrit, original packed cells. All conditions measured in quadruplicate. Curves shown for cells from three individual cattle with red cell K 77, 56, 26 mmol per 1 cells. Data were normalised as % maximum ouabain-sensitive ATPase activity (at 5 mM K). Actual maximum ouabain-sensitive ATPase activities at 5 mM K; upper curve, (77 mmol K per 1 original cells), ATPase 375 nmol P_i per mg protein per h; middle curve, (52 mmol K per 1 original cells), ATPase 660 nmol P_i per mg protein per h; lower curve, (26 mmol K per I original cells), ATPase 260 nmol P_i per mg protein per h.

[3] Fortes, P. A. G., Ellory, J. C., and Lew, V. L., *Biochim. biophys. Acta.*, **318**, 262 (1973).

DR SCHATZMANN REPLIES: The marked variability of the K affinity of the internal Na site found by Dr Ellory renders untenable my tacit assumption that the ATPase activity measured at 10 mM K and 100 mM Na reflects the number of pump sites per cell. But unless our conditions of Na concentration, *p*H and ionic strength considerably enhance the effect due to different affinities it does not seem to account completely for the variability of the Na+K−ATPase which we reported. From the regression in our experiments cells with $[K]_{cells} = 77$ mmol l^{-1} might be expected to have 4.5 times the ATPase activity of those with 26 mmol l^{-1}, whereas the curves shown above only yield a factor of about 1.4 at 10 mM K. Yet I fully agree with the conclusion that the internal K affinity seems more important than the number of pump sites per cell in determining the cellular K concentration.

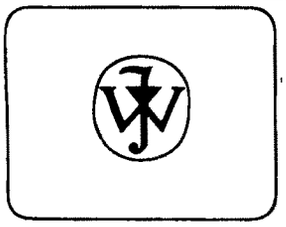
University of Bern, Switzerland

No chromosome 9q+ in Ph¹-negative CML

SIR,—To demonstrate that in Ph¹-positive cells the additional band at the end of the long arms of chromosome 9 (9q+) stems from chromosome 22, Rowley[1] suggested the examination of metaphases derived from bone marrow from patients with Ph¹-negative chronic myelocytic leukaemia (CML). We studied the chromosomes of three such patients, two of whom had symptoms considered to be characteristic for Ph¹-negative CML[2], that is, mild leukocytosis, anaemia, severe thrombocytopenia and discrete splenomegaly.

Case 1 died of a cerebral haemorrhage 3 months after first presentation. Case 2 entered blastic phase and died 20 months after CML had been diagnosed; chromosomes were studied during blastic phase. Case 3 has typical CML and is well 3 yr after the diagnosis has been established.

The chromosome banding pattern was obtained by the trypsin-saline-Giemsa method. The karyotype of case 1 was normal, 46,XY. Case 2 had two clones; the major clone (60%) had the karyotype 47,XY, 20q-,+21 and the minor clone (40%) had 46,XY,20q-. In case 3 the marrow cells revealed a missing Y on several occasions; the karyotype was 45,XO while the PHA-stimulated lymphocytes were chromosomally normal.



Chromosome 9q+ could not be detected in any metaphase of the Ph¹-negative cases. Thus, these findings corroborate Rowley's assumption[1] that the additional material on chromosome 9 comes from chromosome 22. Furthermore, an abnormal banding pattern which would characterise Ph¹-negative CML could not be seen. This may be related to the finding that patients with Ph¹-negative CML represent a rather heterogenous group[3].

WILEY INTERSCIENCE

WATER CIRCULATION IN THE ARCTIC BASIN

by **A. F. Treshnik** and **G. I. Baranov,** *Hydrometeorological Publishing House, Leningrad.*

This new book discusses the general circulation of the world ocean and shows that it is now one of the most important mechanisms of the redistribution of heat that is received by the earth from the sun and given off into space. The movement of water in the Arctic Basin is an inseparable link in this chain. But this is not the only reason why it should be studied. The variable circulation of the surface waters largely determines fluctuation of ice conditions in tributaries of the Arctic Ocean and consequently affects navigation conditions along the Northern Sea Route. To all citizens of this planet

Let's come down to earth

IUCN 1948

Few themes, if any, can be so important to the future of our planet as is
ENVIRONMENTAL CONSERVATION

The problems we are facing today have been coming for fifty years. We did have warnings, nevertheless problems have become crises.
And time is moving on.
Development is necessary to
MAN and NATURE
but so is careful planning, as well as truly international communication and understanding.

It is therefore that the new quarterly journal
ENVIRONMENTAL CONSERVATION
is published by Elsevier Sequoia S.A., Lausanne, for the
Foundation for Environmental Conservation,
with the collaboration of the
International Union for Conservation of Nature and Natural Resources (IUCN),
International Conferences on Environmental Future (ICEF),
World Environment and Resources Council (WERC),
and with the support of
World Wildlife Fund (WWF).

The new journal
ENVIRONMENTAL CONSERVATION
advocates action for the protection and amelioration of the environment of Man and Nature in this ever-changing world.

Topics range from pertinent case-histories of the past and present to rational use of resources, foreseeing ecological consequences, enlightened environmental policy, anti-pollution measures, low-impact development, environmental education and law, and ecologically sound management of all land and fresh water, sea and air, for the lasting future of EARTH's fragile biosphere.
Emphasis is intended to be on the environment of living things – including MAN – and hence on the maintenance of viable ecosystems, whether natural or otherwise, sound ecology being the keynote.
Conferences and meetings, reviews and notices, will establish
ENVIRONMENTAL CONSERVATION
as the much-needed forum for all citizens of this planet who wish to conserve **NATURE**
and make a better world to live in for **MAN.**

Founded and edited by
Prof. Dr NICHOLAS N. POLUNIN
the journal is supported by Conferences & Review Editor M.A. Farid
Editorial Assistant N.V.C. Polunin and thirty-five Advisory Editors covering between them all the main subjects and international agencies involved.

Research and survey articles to be published in Volume 1, 1974 include:

Human Population and Environmental Problems, Prof. Paul R. Ehrlich (USA)

The Expanding Sahara, Prof. J. L. Cloudsley-Thompson (UK)

Hazards of Nuclear Fission Power and the Choice of Alternatives, Prof. John T. Edsall (USA)

Man-made Ecosystems and Nature Conservation, Prof. Erik Kumari (USSR)

Builders of the Universe

The Astronomical Revolution: Copernicus–Kepler–Borelli. By Alexandre Koyré. Translated by R. E. W. Maddison. Pp. 531. (Hermann: Paris; Methuen: London; Cornell University: Ithaca, July 1973.) £6.50.

The Cosmology of Giordano Bruno. By P. H. Michel. Translated by R. E. W. Maddison. Pp. 306. (Hermann: Paris; Methuen: London; Cornell University: Ithaca, July 1973.) £4.50.

THE writings of the late Alexandre Koyré never fail to reveal the intimacy of the union between the history and the philosophy of science. His interpretation of *The Astronomical Revolution*, first published in French in 1961 and now in an English translation is, to quote the author's own expression "the history of the evolution and transformation of the key concepts" (page 9) in astronomy as opposed to a history of astronomy. This distinction arises from the fact that Koyré took no account of advances in observational methods and techniques, since he was of the opinion that these had virtually no influence upon the metaphysical revolution which he is consciously seeking to epitomise through Copernicus, Kepler, and Giovanni Alfonso Borelli. He has, as it were, defined practical astronomy out of existance as being irrelevant to his purpose of exposing both "hidden and acknowledged motives and incentives" (page 18) in the literary legacies of these three men.

The fact that he himself regarded this dichotomy between theory and observation as "rather strange" (page 9) indicates that he might have been prepared to concede the importance of observational astronomy if he had not been bound by his own ontological terms of reference. He cites Rheticus's view that it was Copernicus's success in explaining the lunar theory without equants which encouraged him to carry his explanation further, without stressing that the latter's initial dissatisfaction with Ptolemy's lunar theory was founded upon the observation that the Moon's parallax and angular diameter "differ little, or not at all, from those that are observed at conjunction and opposition" (page 40). Though no one would deny that Copernicus's own observations seem to have been few and their accuracy no better than those of Ptolemy, there are some who are not prepared to accept the inference that observational astronomy had little significance upon the former's belief in the Earth's axial rotation (see J. R. Ravetz, *Scientific American*, **215** 88-98, 1966) Since Koyré placed his entire emphasis upon the heliocentric hypothesis and neglected the question of the Earth's diurnal motion he cannot be challenged on this score, but one might well query the justification of according such an unequal status to these historically inseparable axioms of Copernican astronomy.

The author's interpretation of Kepler's achievements occupy roughly two thirds of this book. Kepler's discovery that the planetary orbits are elliptical with the Sun at one focus—his first law—is attributed to the fact that he was trying to explain discrepancies between theory and observation within the framework of a celestial physics conceived long before he had access to Tycho Brahe's data. On this ground the latter are regarded as having been of little importance to Kepler's rejection of Ptolemy's time-honoured kinematical model of circles and spheres. It is nevertheless true that Kepler derived all three of his laws empirically after years of trial and error in trying to fit Brahe's planetary observations to his physically erroneous model of the solar system. Had the observations of Mars, in particular, been intrinsically less reliable, more dispersed spatially, or more restricted temporally, Kepler—despite his unquestionable genius—would now be featuring much less boldly in the history of science.

The significance attached by Koyré to Borelli is due principally to the latter's recognition that circular motions produce centrifugal forces. Here the thought is considered to be more important than the deed, since Borelli's speculations in his *Theoricae Mediceorum Planetarum* (Florentiae, 1666) were not sufficiently clear to lead to any predictable results. He did not analyse the phenomenon of curvilinear motion into its constituent components and gave no explanation of the origin of the centrifugal tendency, merely seeking to establish the necessity of a constant central force by an appeal to experiment. Koyré sees in him a true disciple of Galileo, who adopts the same methodological approach of using theory to guide experiment "which confirms, or invalidates, the theory, and provides firm data relating to the matter under investigation" (page 469). Stillman Drake has recently cast doubts upon whether this image of Galileo which Koyré himself, in *Études galiléenes*, has done much to propagate, comprehends a true reflection of his epistemology (see *Scientific American*, May, 84-92; 1973) but whether this will affect future assessments of Borelli's work is difficult to say. The latter's deductive approach is here attributed to "the sterility of observation, pure and simple" (page 471), and the telescopic observations which he had been making for years on Jupiter's satellites are supposed merely to have provided an excuse for publishing his theory of their motions. But one cannot escape the fact that this theory was developed from the ellipticity of planetary orbits—a 'fact' derived observationally by Kepler and accepted by Borelli on observational grounds (as an extract from his writings quoted on page 474 clearly reveals). Thus here again it ought to be recognised that Koyré's philosophical distinction, though heuristically convenient, is historically inadequate.

In another of his writings, Koyré once claimed that the greatest achievement of the scientific revolution was the destruction of the cosmos which it had been the greatest achievement of the Greeks to create. The determinative factor in this dramatic ontological transformation was the collapse of the finite bounded Aristotelian Universe and the consequent rejection of a central point. This notion originated not from Copernican astronomy but from an admixture of neoplatonic philosophy and commentaries such as that of Nicolas of Cusa upon the Aristotelian vision of the heavens. *The Cosmology of Giordano Bruno* is concerned with this metaphysical revolution which precedes yet transcends the astronomical revolution of Copernicus, Kepler and Borelli. Even the Sun loses its privileged position in an infinite Universe, but the Copernican (and Pythagorean) postulate of the Earth's diurnal rotation can be seen as a logical corollary to the observed fact that all the stars seem to be carried round the heavens at the same uniform speed in a westerly direction. Thus a belief in Bruno's cosmology, with its emphasis on the infinity of the Universe might have acted as a stimulus to the acceptance of the new astronomy, and *vice versa*. Here, however, the late Paul-Henri Michel is not interested in exploring possible connections between the seventeenth

Chapman & Hall,

London EC4P 4EE.

Journal of Neurocytology

EDITORS: E. G. GRAY and A. R. LIEBERMAN, both in the Department of Anatomy, University College London.

The policy of the *Journal* is to publish, with minimum editorial and production delay, high-quality research papers, analytical reviews, and occasional letters. In order to achieve this aim more completely the journal will be published as a bi-monthly rather than a quarterly journal from the beginning of 1974. Papers deal with fine structural studies and associated cytochemical, biochemical, physiological and pharmacological studies of neurons, receptors, synapses, neuro-effector junctions, glia and other elements of the peripheral and central nervous system. Studies of both vertebrate and invertebrate nervous systems under normal, experimental, and pathological conditions are all suitable for the *Journal*.

Important features are the editorial emphasis on adequate illustration of papers and the publisher's concern for high-quality reproduction of plates.

Annual Subscription 1974 (6 issues): U.S.A., Canada and Mexico $49.50 U.K. and all other territories £18.75. Full details and a specimen copy are available on request.

Topology and Normed Spaces

G. J. O. JAMESON,

Chapman & Hall Mathematics Series

Hardback: June 1974: 424 pages: £5.80 Limp cover: £3.80

Based on courses given at the Universities of Warwick and Innsbruck, this book provides a general introduction to topology and then uses topology to introduce normed spaces. Normed spaces provide the most natural examples of topological spaces and also set the scene for many of the best applications of the theorems of general topology. This approach should be invaluable for students who have done some elementary analysis and linear algebra.

Further details of mathematical books and a list of stockists is available from the publishers on request.

century reaction against Bruno's heresies and the slow initial reception of Copernican astronomy, but rather with examining the internal consistency of the cosmological ideas in Bruno's writings; it being the central thesis of his book that the latter embody a systematic philosophy of nature. The work is consequently likely to have a greater appeal to philosophers of science than to historians of science specialising in Copernican studies.

Though drawing upon statements from all Bruno's extant cosmological and moral writings—these date from 1582 to 1592—the author is concerned principally with the contents of the three vernacular dialogues *La cena de le ceneri, De la causa, principis et uno, De l'infinito immenso et mondi* of 1584, and the trilogy of Latin poems *De minimo, De monade, and De immenso* composed seven years later. These, in his opinion, "have in common a scholarly, careful and almost meticulous method of utterance" (page 50). Yet his attempts to justify his belief in the compatibility of Bruno's statements require all his powers of exigesis and are at times less than convincing. For example, he dismisses an inconsistency between Bruno's views in *De la causa* and the moral treatise *Eroica furori* regarding the possibility of attaining supreme metaphysical knowledge, as resulting from "two complementary aspects of a single consistent thought, rather than two different modes" (page 58). He confesses that Bruno's ideas concerning the indivisibility of the soul are "scattered, and sometimes contradictory" (page 116); admits that Bruno's answer to the question of continuity in the material Universe "was not vigorously asserted" (page 132); and tells us that "we must resign ourselves" to the fact that Bruno's conception of an aether "retains its ambiguous and mysterious character" (page 140). Moreover, he remarks upon Bruno's "unfitness for certain kinds of mathematic reasoning" (page 145); and so on. It would seem much less difficult to defend the opposing thesis that Bruno was not quite up to the task of producing a consistent poetic, polemic, and aphoristic description of the Universe; and that his philosophical utterances on its infinity and homogeneity, the plurality of worlds, and animism in nature, were little more than a regurgitation of ill-digested ideas from Albertus Magnus's and St Thomas Aquinas's discussions of the doctrines of David of Dinant, and from works by Nicolas of Cusa and Marsilio Ficino.

Dr Maddison's translations of both Koyré's and Michel's books are excellent, and misprints are few. In the former, the year of Tiedemann Giese's letter to the magistrates of Nuremberg complaining of Osiander's breach of faith to Copernicus is wrongly printed on page 37 as 1523 (instead of 1543). In the latter (page 36), the twentieth century French scholar Etienne Gilson is said to have been writing in 1628, and a rather odd mistake on the book jacket is the statement that Bruno was burnt as a heretic in Rome in 1589 (rather than 1600). But these are but minor errors. English-speaking historians and philosophers of science will undoubtedly be pleased to have these well documented studies of sixteenth and seventeenth century thought accessible in their native language, at relatively modest prices.

ERIC G. FORBES

Rockefeller Research

The Arthropod-Borne Viruses of Vertebrates: An Account of the Rockefeller Foundation Virus Program, 1951–70. By M. Theiler and W. G. Downs. Pp. xxviii+578. (Yale University: New Haven and London, June 1973.) $25; £10.50.

THE agent causing yellow fever was shown to be a virus only in 1927. By 1950 about 20 other arthropod viruses, or arboviruses, had been discovered, mostly as a result of work primarily on yellow fever, but now more than 300 such viruses are known. This great increase in the numbers of known arboviruses is largely due to the Division of Medicine of the Rockefeller Foundation. Workers from here first studied yellow fever in 1914 and played a major part in the isolation of the virus, in elucidating the epidemiology of the disease, and in devising control measures, recognised by the award of a Nobel Prize in 1951 to the late Dr Theiler for work on the development of an effective vaccine.

Because of a lack of knowledge about the significance of arboviruses other than yellow fever in causing morbidity and mortality in man or his domestic animals, the foundation decided in 1950 to start a major research programme to investigate them, particularly in tropical countries where they are prevalent. In addition to the existing yellow fever laboratories supported by it in Entebbe, Lagos and Rio de Janeiro, the foundation, over several years, established new field laboratories in Poona, Cairo, Johannesburg, Ibadan, Port of Spain, Belem and Cali. Although staff members were assigned to these laboratories, the subprofessional staff were recruited almost entirely from local people, and an integral part of the programme was the training of workers from the coun-

tries themselves so that they could eventually take over the laboratories. As well as financial support, travel grants and fellowships were given to laboratories working on arboviruses in many other countries.

The Rockefeller Foundation Virus Laboratory, New York, which moved to Yale in 1964 as the Yale Arbovirus Research Unit, acted as a coordinating laboratory, as a centre for training and for the evolution of new techniques, and as a reference laboratory for identification and classification of the spate of new arboviruses which were isolated. This intensive research continued for a period of some 20 years but, with a change of emphasis in the activities of the foundation, has recently been curtailed, some would think prematurely.

The purpose of this book is chiefly to give an account of the activities of the central and, to a lesser extent, of the field laboratories. Part 1, consisting of four chapters, deals with the development, application, and interpretation of the classical techniques of neutralisation, haemagglutination-inhibition, and complement fixation tests as applied to the diagnosis of arbovirus infection in man and animals and the identification of isolates. Previously unpublished material is used to illustrate some points but scant reference is made here, or elsewhere, to the development of new techniques such as the use of mammalian or insect cell cultures for arboviruses.

In the second and largest part, comprising ten chapters, the principles of the method of classification of arboviruses into antigenic groups, evolved at the Rockefeller Foundation Laboratories, is explained. This is followed by a systematic description of most of the arboviruses known at the time of writing, from Group A to the ungrouped viruses. Details are given of the isolation, of the classification and of the epidemiology of the viruses in man and animals, as far as this is known, and of their importance as pathogens. Many are still in search of a human disease with which they can be identified. In the third part, of seven chapters, there are general discussions about the world distribution of arboviruses, and of their vectors and vertebrate hosts, which give useful summaries. These are followed by brief discussions of their significance for man and clinical manifestations. Finally, the specific problems of dengue and yellow fever in the Caribbean are described.

As a monument to the notable work of the Rockefeller Foundation in the field of arboviruses this book fulfils its primary objective. As a reference book for the serious worker it is less satisfactory. Much is omitted about fundamental work, some of the epidemiology is dealt with perfunctorily, and there is little reference to recent manifestations such as the dengue shock syndrome. The most useful sections of the book are the second part and some of the third which, with the extensive bibliography, are ready sources of knowledge.

C. C. DRAPER

Pituitary

The Pituitary Gland: A Comparative Account. By R. L. Holmes and J. N. Ball. Pp. x+397. (Biological Structure and Function.) (Cambridge University London, February 1974.) £10; $28.50.

THE first chapter of this book deals briefly, but adequately, with a general appraisal of the embryology, morphology and physiology of the pituitary gland. The next few chapters deal with morphology and cytology of the various parts of the gland in mammals beginning with the pars distalis. Perhaps the most confusing aspect of pars distalis cytology lies in the nomenclature used to describe different cell types. Although a functional name is to be preferred, for example thyrotroph for TSH cells, in many cases this is not possible, and the use of other systems of nomenclature, though no fault of the authors, makes this a difficult chapter to read.

A major fault in this chapter, which also deals with staining techniques, and the ultrastructure of the pars distalis, lies in the omission of any reference to the use of the peroxidase-labelled antibody method for identifying cell types. This technique has been widely used in both light and electron microscope studies in the last few years.

The beauty of the opening colour plate whets the appetite for the subsequent micrographs; the identification of cell types in electron micrographs is certainly adequately described, but nearly all of the electron micrographs are of poor quality.

Chapter 4 deals with the pars tuberalis and pars intermedia, serving to point out the lack of knowledge of these two subdivisions of the pituitary. A general outline of the neurohypophysis, which includes the median eminence, follows in chapter 5, with chapter 6 covering the basis for a neural control of the pars distalis. There is a certain amount of repetition of chapter 1 here, but the objective approach of the authors makes this chapter very useful for anyone looking for a brief appraisal of the historical and comparative evidence, for and against, a neurovascular control of pars distalis function.

The next eight chapters are concerned with a comparative account of pituitary structure and function, with a greater emphasis on structure, and it is in these chapters that the book becomes an invaluable information source for both research workers and teachers. The importance of the portal vessels is not diminished, but to be able quickly to refer to those members of the animal kingdom which have an anterior pituitary gland, but no portal vessels, demonstrates that our dogmas sometimes need deflating.

In each of these eight chapters, information is divided under subheadings; for example in the chapter on teleosts a general paragraph is followed by sections covering the overall structure in several teleost species. This is followed by a description of the histophysiology of the pars distalis, with very useful sections devoted to different cell types from both a morphological and a physiological viewpoint. Hypothalamic control of the teleost pars distalis is then considered from the physiological viewpoint, with several subsequent pages devoted to the pars intermedia. A consideration of neural lobe and hypothalamus follows, and anatomical aspects of hypothalamic control of the anterior pituitary end the chapter. I feel that if these subdivisions had been tabulated, either in the list of contents, or at the beginning of each chapter, the use of this book as a reference source would have increased further.

But any book which goes into such detail in describing the pituitary gland in vertebrate groups from fish to man will be a useful addition to libraries.

H. M. CHARLTON

Not only frog and rabbit

Comparative Vertebrate Morphology. By Douglas and Molly Webster. Pp. xiv+517. (Academic: New York and London, January 1974.) $32. £15.35.

THIS is an interesting new book on vertebrate morphology, set in clear, readable type and well illustrated. The adjective "comparative" in the title is fully justified, each organ system being illustrated for an example of each extant class or order, as appropriate, and the text similarly trying to cover each extant group. The book certainly does not follow the usual 'dogfish–frog–rabbit' format. Moreover, the text is heavily slanted towards a functional morphological approach, which will undoubtedly make more interesting reading for students than several of the rival texts. The book concentrates on extant vertebrates, though the phylogenetic relationships expressed by current palaeontological opinion are fully appreciated, and used frequently in diagrams. There are a

NEW FROM LONGMAN

Companion to Biochemistry
A T Bull, J R Lagnado, J O Thomas and K F Tipton
This book is designed to fill the gap between basic texts and specialist reviews by providing a collection of about twenty articles on various important aspects of biochemistry. Suitable for advanced undergraduate teaching in biochemistry.
£7.00 net

Theory of Linear & Non-Linear Programming
S Vajda
This book gives a logical and consistent exposition of the theory of the subject assuming only a knowledge of linear algebra and of elementary differential calculus. It concentrates on theory rather than on algorithms, and will be found to be an appropriate text for courses on the mathematical theory of decision sciences in both operational research and industrial engineering. Pure mathematicians will also find much interest in this book offering, as it does, many opportunities for the derivation of further results. £2.95 net

Tropical Forest and its Environment
K A Longman and J Jenik
This is the first book in over 70 years to give a full and dynamic picture of the world's tropical forests from the standpoint of plant ecology and physiology of tree growth. This book analyses the fundamental reasons for the dwindling areas of natural forest. The authors draw attention to the need to study and understand the functioning of these great natural plant communities before they are lost. £1.95 net

Longman 1724-1974

few minor errors, for example the ball-and-socket joint is a characteristic of many placoderms, not just *Dinichthys* (page 22), and the description of the mole's digging musculature (page 146) is decidedly misleading. But errors seem to be reassuringly few in number, and the book can at least be commended as an informative text.

The preface says that the book has been written for students attending a one semester course on vertebrates, and before one can recommend it as such, it must be considered in relation to its rivals, especially Romer's *Vertebrate Body* which I recommend to my students. In this comparison, the Webster's book scores heavily on its functional approach—Romer is by contrast rather dry reading. Romer's book is, not surprisingly, better grounded in palaeontology, and gives a better account of the skeletal systems. The Websters on the other hand, give a better account of the nervous system. In value, however Romer's book is so superior that the comparison is hardly worth making—it contains about 35% more figures, 16% more pages, a much better biblography, yet costs only 30% of the Websters' book. It is difficult to know quite why this new text should be so expensive, but the 45 mm margins to the text are wasteful and the insert of six unhelpful colour plates seems an extravagance. Romer's use of colour on ordinary text figures is far more satisfactory.

In summary, then, this text is sufficiently different from its rivals to warrant a place in university libraries. On simple economic arguments, it cannot possibly be commended to students.

D. W. YALDEN

Snake bite

Toxicology and Pharmacology of Venoms from Poisonous Snakes. by John H. Brown. Pp. xiv+184. (Thomas: Springfield, September 1973.) $13.75 cloth; $9.95 paper.

I FIND little merit in this book. For one thing the production is poor. The reproduction of most of the 84 colour plates is bad, of some very bad and of two upside down. It is claimed to be encyclopaedic but the widespread and dangerous viper, *Echis carinatus*, receives scant mention and none in the chapter on symptomatology and treatment. Snakebite in England is mentioned but not in the subcontinent of India!

I cannot make out to whom the book is addressed. The chapter on pharmacology is in technical language and contains information likely to interest only research workers. The factors which make the distinctions between those known to be dangerous, those only potentially dangerous and harmless snakes are only vaguely indicated. There is a full list of poisonous snakes around the world but not a hint on how to go about identifying a specimen. Those who do not already know snakes will learn little.

The best parts deal with yields and preparation of venom and assessment of toxicity. These seem, however, unlikely to justify the purchase price to many readers.

GARTH UNDERWOOD

Above the atmosphere

Radio Wave Propagation. By Armel Picquenard. Pp. vi+343. (Macmillan: London and Basingstoke, April 1974.) £10.

THIS year is the fiftieth anniversary of the experimental proof of the existence of the ionosphere, so that there is a special interest in the subject of Professor Picquenard's new book. It is refreshing to be able to welcome such a book from a Brazilian author, when there have been so many books on related subjects from more northerly parts of the American continent.

The whole range of subjects in radio propagation is reviewed. The early chapters are concerned with the troposphere, including both stratified media and scatter propagation, and with the Earth's surface, including both smooth and irregular terrain and diffraction by obstacles. The chapter on the ionosphere deals with its formation and temporal variation and discusses propagation mainly for an isotropic plasma.

The object is to show how to assess a given radio communication link. More than one third of the book is devoted to the last chapter entitled "Practical Calculation of Radio Links", but much of this space is occupied by charts and diagrams, for example a series of 24 maps of the world showing how the intensity level of atmospherics varies with frequency and with time of day, through the year.

This book is for the practical communications engineer who wants to know the answers and is prepared to take the theory on trust. It is not for the more serious scientist who wants to understand the theory and apply it to new situations. There are errors in some of the formulae although many of them are only minor. On the whole it is a useful book.

Announcements

Awards

H. H. Lamb has been given the **Murchison Award** of the Royal Geographical Society for his work in the field of climatic change.

Graham Highman has been awarded the **De Morgan Medal** and **Paul M. Cohen** the **Senior Berwick Prize** of the **London Mathematical Society.**

Errata

In the article "Effects of bicuculline on functions of inhibition in visual cortex" by D. Rose and C. Blakemore (*Nature*, **249**, 375; 1974) the following corrections should be made: the last sentence of para 1 on page 376 should read 'The erratic mechanical stability of the preparation for topical application used in some experiments, has meant that few cells have been fully analysed so far.'; line 12, para. 6 should read '. . . best orientation. This suggests the presence . . .'; and in Table 1, in the column "cortical layer" the first entry should be VI, the third V and the fourth IV.

In the article "Do D-glucosamine and D-galactosamine form a part of the specific receptor sites for the competence substance on the cell wall of *Pneumococcus*?" by M. Kohoutova and J. Kocourek (*Nature*, **247**, 277; 1974) the first sentence of the paragraph under Fig. 4 should read 'The presence of a 2-N-acetamido-4-amino-2,4,6-trideoxyhexose was also reported in the C substance[13]', and not as printed.

In the article "Behavioural and physiological bases of drinking inhibition in water deprived rats" by E. B. Blass and W. G. Hall (*Nature*, **249**, 485; 1974) the first word of the fourth column of Table 1 should be drink and not pre-load.

APPOINTMENTS VACANT

MARINE PHYSIOLOGIST

The Rosenstiel School of Marine and Atmospheric Science has an opening for a whole animal physiologist with at least a secondary interest in environmental physiology, beginning as early as January, 1975. Responsibilities will include teaching a graduate level course on the physiology of marine animals. Appointment will be at a rank and salary commensurate with experience and qualifications. Applicants must have completed the Ph.D. degree. Send curriculum vitae and names of five referees to Dr Barrie F. Taylor, Chairman of Search Committee, University of Miami, R.S.M.A.S., 4600 Rickenbacker Causeway, Miami, Florida 33149. Applications close on August 31, 1974. (2509)

DIRECTOR

The Jackson Laboratory invites applications for the position of Director of the Laboratory, which will become open on October 1, 1975. Qualified applicants are invited to submit a curriculum vitae and summary of experience to one of the following:

Dr James D. Ebert, Chairman, Search Committee, Marine Biological Laboratory, Woods Hole, Massachusetts 02543;
Dr James F. Crow, Member, Search Committee, Department of Medical Genetics, University of Wisconsin, Madison, Wisconsin 53706;
Dr Douglas L. Coleman, Secretary, Search Committee, The Jackson Laboratory, Bar Harbor, Maine 04609.

AN EQUAL OPPORTUNITY EMPLOYER. (2508)

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF BOTANY
LECTURER IN APPLIED ECOLOGY

Applications are invited for the post of Lecturer in applied ecology commencing on October 1, 1974. Applicants should possess a good honours degree and postgraduate experience in plant ecology, soil science or agronomy. An interest or experience in applying ecological principles to solving practical problems of the environment such as land reclamation or pollution would be an advantage.

There will be excellent opportunities for collaborating with a very active research group in environmental rehabilitation which has strong links with industry and local government.

Initial salary within the range £2,118 to £2,412 on a scale rising to £4,896 per annum.

Applications together with the names of three referees should be received not later than July 19, 1974 by the Registrar, The University P.O. Box 147, Liverpool L69 3BX from whom further particulars may be obtained. Quote ref. RV/N/276073. (2495)

UNIVERSITY OF MANCHESTER
DEPARTMENT OF MEDICAL BIOCHEMISTRY

Applications are invited for a Postdoctoral RESEARCH ASSOCIATESHIP financed by the British Heart Foundation. The project involves the isolation of endothelial cells from major blood vessels, their establishment in culture and studies of the synthesis of the collagen and glycoprotein components of the endothelial basement membrane. Experience in cell culture and/or protein synthesis would be advantageous. The appointment from October 1, 1974 is tenable for two years. Salary range p.a.: £2,118 to £2,412 plus F.S.S.U. Applications giving the names of two referees should reach the Secretary, Department of Medical Biochemistry, University of Manchester Medical School, Manchester M13 9PT, as soon as possible. (2481)

Ministry of Agriculture, Fisheries and Food
Food Science Division, Norwich

Chemist

■ **Join Unit studying reactions of additives and storage effects on food** ■ **Initially work involves investigating changes in baking quality of flour during storage** ■ **Help identify basis for variability in storage stability.**

□ Degree, HNC or equivalent in chemistry-based subject □ At least 2 years' post-graduate experience □ Some biochemical, food or natural product orientation □ Age under 30 □ Appointment as Higher Scientific Officer (£2221–£2854, under review, plus threshold payments) □ Ref: SB/10/AE.
□ Application forms (for return by 18 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Ministry of Agriculture, Fisheries and Food
Food Science Division, London

Food Scientist/ Technologist

■ **In Information Unit** ■ **Collect, distribute and use scientific and technical information on various aspects of food science and technology, nutrition and toxicology.**

□ Degree, HND in Food Science/Technology □ Experience of information work or work in food industry an advantage □ Age under 27 □ Appointment as Scientific Officer (£1663–£2557, under review, plus threshold payments) □ Ref: SB/9/AE.
□ Application forms (for return by 18 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

British Museum (Natural History)

Assistant Cytotaxonomist

■ **Routine organisation of laboratory and cultural facilities at Chelsea Physic Garden** ■ **Undertake cytological and other biosystematic investigation in support of research projects.**

□ Degree, HNC or equivalent in Botany □ Practical experience in relevant fields desirable □ Age under 27 □ Appointment as Scientific Officer (£1662–£2557, under review, plus threshold payments) □ Ref: SB/28/DK.
□ Application forms (for return by 22 July 1974) from Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, telephone Basingstoke 29222 ext. 500 or London 01-839 1992 (24 hour answering service).

Science group
CIVIL SERVICE

(2668)

PROFESSOR OF BIOMETRY OR BIOSTATISTICS

Applicants are invited to apply for a new senior faculty position in the Statistical Science Division, Department of Computer Science, SUNYAB, starting in September 1975. Applicants should have an outstanding record of research, training and collaboration in the Health and Statistical Sciences. Responsibilities include teaching, developing curriculum for undergraduate and graduate courses in Biometry and Statistical Science for specialists and non-specialists, and active participation in the collaborative activities within the Statistical Laboratory. Applications from women and minority candidates will be especially welcome. Please send curriculum vitae to:

Professor Marvin Zelen, Chairman
Search Committee
Statistical Laboratory
SUNY at Buffalo
4230 Ridge Lea Road
Amherst, New York 14226 (2569)

PORTSMOUTH POLYTECHNIC
DEPARTMENT OF CHEMISTRY

Application are invited for a

TEMPORARY LECTURESHIP IN MATERIALS TECHNOLOGY

from graduates with a specialised knowledge of the chemistry and application of PLASTICS/PAINTS and other PROTECTIVE COATINGS.

The appointment will be made either at Lecturer Grade I or Lecturer Grade II level according to qualifications and experience.

Salary scales: Lecturer Grade I: £1,800 to £3,045 per annum; Lecturer Grade II: £2,700 to £3,474 per annum.

Application forms and further particulars may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth, PO1 2QQ, to whom completed applications should be returned by July 15, 1974. Please quote reference D50. (2577)

HARWELL

Physics of Materials

The Physics Divisions at Harwell covera broad range of activities reflecting the Laboratory's breadth of interests and knowledge, with particular expertise and responsibilities in the application of new techniques to nuclear and non-nuclear materials problems, in neutron beam research and in laser applications.

Applications areas of particular interest and under development are:

Liquid Physics
Image Analysis
Laser Applications

Our LIQUIDS experience is in the study of liquid movement, and flow-induced vibration using optical techniques including lasers.

The IMAGE ANALYSIS studies are developing new electronic techniques of image processing and analysis.

In LASER APPLICATIONS our interests cover the use of both low and high power lasers for the study of the physics of materials.

We are looking for people with post-graduate experience in related areas with interest in physics application, and the energy to pursue and develop them. We will appoint either to our permanent staff or to three year Fellowships in a salary or stipend range of £2000-£3500 p.a.

Applications should be sent to:
Appointments Section 'A',
AERE, Harwell, Oxfordshire OX11 0RA.

(2605)

RESEARCH POST AT THE OXFORD HAEMOPHILIA CENTRE

Applications are invited from medically qualified graduate scientists with some experience of research in some aspect of haemostasis for appointment as a member of a small team of Medical Research Council staff working at the Oxford Haemophilia Centre, under the direction of Dr Rosemary Biggs. The successful candidate will be expected to co-operate with other members of staff on projects already progressing at the Centre and to initiate a research project or projects in the general field of interest of the work at the Centre. The work of the M.R.C. staff is integrated with that of the N.H.S. Clinical Unit, many projects being undertaken jointly, and an Honorary Clinical contract with the United Oxford Hospitals may be sought at a level appropriate for the successful candidate. The M.R.C. and N.H.S. staff also work in close co-operation with the staff of the Lister Institute Plasma Fractionation Laboratory and joint research projects may be planned. The appointment will be to the M.R.C. staff on the appropriate scientific grade and will initially be for a period of five years with the possibility of renewal at the end of this period. Superannuation provision.

Applications should be addressed to Dr Rosemary Biggs, Director, Oxford Haemophilia Centre, Churchill Hospital, Headington, Oxford OX3 7LJ. (2477)

ASSISTANT PROFESSOR OF HUMAN GENETICS

Applications are invited from qualified Ph.D. and/or M.D. with educational research background in genetics, biochemistry, and cell biology. Candidate must have significant research accomplishments and teaching capabilities in all of the above areas. Preference will be given to those whose research focus is either in mammalian chromosome structure and function, or biochemistry of genetic variation in eukaryotic (preferably human) organisms.

Please send complete curriculum vitae and three references to: Chairman, Department of Human Genetics, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania 19174, U.S.A.

An equal opportunity—affirmative action employer. (2573)

RESEARCH ON TRANSFERABLE DRUG RESISTANCE ENTERIC REFERENCE LABORATORY

Applications are invited for two posts in the Enteric Reference Laboratory, Public Health Laboratory Service, Colindale, directed by Professor E. S. Anderson. Successful candidates will join a team investigating transferable drug resistance.

(1) A microbial geneticist to study epidemiological and ecological aspects of transferable drug resistance in enterobacteria.

(2) A microbial or molecular geneticist for research on the genetic and molecular characterisation of plasmid transfer systems.

Candidates with a 1st or 2nd class honours degree or a Ph.D. will be considered. Starting salary in accordance with age and experience.

Application with full curriculum vitae and names of 2 referees to Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (2517)

UNIVERSITY OF NOTTINGHAM
SCHOOL OF AGRICULTURE
DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL STUDIES
EXPERIMENTAL OFFICER

Applications are invited for the post of Experimental Officer within the Plant Physiology Section. The duties involve carrying out research on the structure and properties of tobacco. The post would be suitable for a recent graduate in Biology or Biochemistry, who has expertise in preparation of sections for light microscopy and electron microscopy. Determination of nicotine content is also part of the work, and thus experience or at least interest in gas chromatography would be an added advantage. The post is for an initial period of one year, with possible extension to a total period of 2 years, 10 months. Starting salary within the range £1,569; £1,647; £1,725, under review. Application forms from the Staff Appointments Officer, The University, Nottingham, quoting reference 379. Closing date July 7, 1974. (2580)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF CANCER STUDIES

Research Technician, Grade III, is required to work on a project involving a study of the mechanism of carcinogenesis by chemical compounds. Biochemical work, tissue culture work and some animal experimentation will be involved. Preference will be given to candidates with experience in either biochemistry or tissue culture techniques. Applicants must have an ONC in an appropriate subject and several years laboratory experience. Salary will be on the scale £1,650-£1,920. Applications should be sent with a curriculum vitae and the names of two referees to the Personnel Department, University of Birmingham, Birmingham, B15 2TT. Ref. 450/B/264. (2546)

PORTSMOUTH POLYTECHNIC
SCHOOL OF PHARMACY
RESEARCH ASSISTANTSHIP

Applications are invited from graduates with a good honours degree in Pharmacy or a subject which includes bacteriology. Applicants about to graduate will be considered. The successful applicant, who will be expected to register for a higher degree, will work in the general area of competitive growth in mixed cultures of interest to medical microbiology.

Salary scale: £1,320 to £1,420 per annum.

Application forms and further particulars may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth, PO1 2QQ, to whom completed applications should be returned by July 15, 1974. Please quote reference R73. (2576)

THE UNIVERSITY OF NEWCASTLE UPON TYNE
CHAIR OF PHYSICS

Applications are invited from experimental physicists for the Chair which was held until his death by Professor W. R. Hindmarsh. This is the third Chair in the School of Physics (the others being Geo- and Planetary Physics, and Theoretical Physics). Salary in accordance with the Professorial Scale (£5,625 by £96 to £5,721 by £195 to £6,501) with membership of F.S.S.U.

Further particulars may be obtained from the Registrar, the University of Newcastle upon Tyne, 6 Kensington Terrace, NE1 7RU, with whom applications (15 copies), giving the names of not more than three referees, must be lodged not later than August 31, 1974. (Applicants from outside the British Isles may submit one copy only.) (2584)

UNIVERSITY OF DURHAM
DEPARTMENT OF GEOLOGICAL SCIENCES
SENIOR DEMONSTRATOR IN GEOPHYSICS

Applications are invited for the post of Senior Demonstrator in Geophysics in the above Department from October 1, 1974 for two years in the first instance with possible renewal for a third and final year. Preference will be given to candidates with a good single or joint Honours degree in either Geology or Physics and with post-graduate research training in solid-earth geophysics.

Salary will be at an appropriate point on the scale £1,908 to £2,820 with F.S.S.U.

Applications (3 copies) naming three referees, should be sent by July 15, 1974 to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (2582)

UNIVERSITY OF NOTTINGHAM
SCHOOL OF AGRICULTURE
Department of Applied Biochemistry and Nutrition

Applications are invited for a post of Lecturer in Plant Biochemistry within the Department of Applied Biochemistry and Nutrition of the University of Nottingham. Preference will be given to graduates with initial degrees in Biochemistry or Chemistry and with postgraduate experience in Plant Biochemistry. Facilities for research can be provided in several areas of Plant Biochemistry. The salary will be within the range of £2,118 to £4,896 per annum, but the appointment will initially be made within the first three points of the scale. Application forms and further details can be obtained from the Staff Appointments Officer, The University, Nottingham, quoting Reference 378. Closing date July 7, 1974. (2581)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND
FACULTY OF MEDICINE

A new medical school in Canada is expanding its faculty and will make post-doctoral and faculty appointments in the field of Human Biochemical Genetics. Candidates must be prepared to work on human biochemical variation in the context of collaborative population studies though this does not preclude the pursuit of other research interests. Interested individuals should submit applications accompanied by a detailed curriculum vitae to Dr K. B. Roberts, Associate Dean for Basic Medical Sciences, Memorial University of Newfoundland, St. John's, Newfoundland, A1C 5S7, CANADA. (2570)

UNIVERSITY OF RHODESIA
ENGINEERING

A Faculty of Engineering has been established by the University of Rhodesia in Salisbury, to provide four-year Honours degrees in Civil, Electrical, Mechanical, or Inter-disciplinary Engineering, with G.C.E. "A" level entry. Faculty buildings are in process of erection. Professors have already been appointed in the fields of Electrical and Civil Engineering, and applications are now invited for the following:

CHAIR in the field of MECHANICAL ENGINEERING.

LECTURERS/SENIOR LECTURERS with experience in one or more of the following areas (the symbols c, e, or m, imply primary application in the fields of Civil, Electrical or Mechanical Engineering respectively): Building Science (c); Control Systems (e, m); Dynamics (m); Electronic Circuit and System Design (e); Electrical Machines and Power (e); Electromagnetics (e); Fluid Mechanics (c, m); Geotechnology (c); Materials Science (m, e); Mechanical Design (m); Public Health and Water Utilisation (c); Solid Mechanics (m); Structures (c); Telecommunications (e); Thermodynamics (m); Transportation Intrastructures (c).

Minimum qualifications: university degree plus substantial postgraduation experience. (Corporate membership of a Professional Engineering Institution desirable).

Salary Scales (Approx. stg. equiv.): Professor: £7,430 by £277 to £8,812; Senior Lecturer: £5,400 by £216 to £7,128; Lecturer I: £4,905 by £181 to £5,633; Lecturer II: £3,024 by £156 to £3,491 by £173 to £3,836 by £181 to £4,562 by £173 to £4,735. Commencing salary according to qualifications and experience.

Family passages and allowances for transport of effects; installation loan; travel allowance for Sabbatical and Biennial (Professor) or Triennial (Lecturers) visits; superannuation and medical aid schemes. For persons recruited outside Rhodesia, unfurnished accommodation on or near the Campus, and within easy reach of good Junior and Senior Schools, is guaranteed for up to three years.

The University is prepared to consider a Secondment/Contract appointment.

Applications: Six copies, giving personal particulars (including full names, place, and date of birth), qualifications, experience, and publications, and naming three referees, should be sent by August 31, 1974 to the Assistant Registrar (Science), University of Rhodesia, P.O. Box MP. 167, Mount Pleasant, Salisbury, Rhodesia. Applicants from outside Southern Africa should send an additional copy to the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further particulars may be obtained. Some appointments are envisaged for 1974, others for 1975; applicants should state the earliest date available for duty, and also the preferred date. (2587)

UNIVERSITY OF GLASGOW

Applications are invited for the post of Project Engineer to the Kelvin Laboratory. The Engineer is responsible for the maintenance and operation of the 130 MeV electron linear accelerator which is used for research in nuclear structure physics. The techniques involved include high power s-band microwave generation, ultra high vacuum, electromagnetic beam analysis and control systems for electrical and fluid supplies.

The duties involve direction of the highly experienced technical staff in these activities, diagnosis and elimination of faults, and development leading to improved performance of the accelerator in experiments.

The post is remunerated on the new University Lecturer's scale between £3,462 and £4,896 per annum, which will be effective from October 1, 1974, the appointment depending on experience and age.

Further details will be supplied on request. Applications, with the names of three referees, should be sent to Professor G. R. Bishop, Kelvin Laboratory, N.E.L., East Kilbride, not later than July 15, 1974.

In reply please quote Ref. No. 3486M (2597)

BRITISH MUSEUM Natural History

Educational Technologist

To join a team of scientists and designers engaged in the development and production of a comprehensive new exhibition scheme for natural history including biology and geology.

The successful candidate will assist the team to conceptualize and organize the subject matter in order to define objectives, and will be expected to devise methods of presenting complex information and to evaluate exhibits and related publications.

Appointment will probably be as Senior Scientific Officer, requiring a good honours degree in a scientific subject and at least 4 years postgraduate experience. Graduates with a minimum of 2 years experience will, however, be considered for appointment as Higher Scientific Officer. Preference will be given to those with a broad knowledge of biological sciences and experience as an educational technologist.

SALARY: SSO, £3026-£4123; HSO, £2449-£3082.

For further details and an application form (to be returned by 12 July 1974) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke 29222 ext. 500 or 01-839 1992 (24 hour answering service). Please quote SB/29/DK. (2686)

POWER STATION CHEMIST

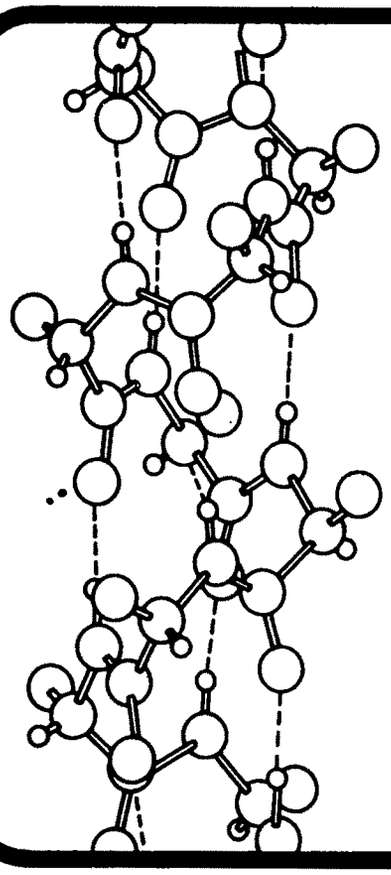
(salary: HK$6,415 to HK$7,010 per month. Sterling £6,350 to £6,950 a year)

required by

HONG KONG GOVERNMENT

Office of the Water Authority

Applications are invited from suitably qualified and experienced Power Station Chemists for appointment as Senior Waterworks Chemist (Desalting) to take charge of all chemical services at the Lok On Pai Desalting Plant. The plant is the largest and most modern of its kind in the world operating on a multistage flash distillation process, producing 40 MGD of fresh water from the sea. The plant will comprise power station equipment, in addition to the evaporators.



Duties will include the setting up of laboratory services, analyses of boiler water, fuel, lubricating oils, sea water etc., corrosion monitoring and pollution surveys. The Senior Chemist will head a team of assistants who will carry out this work and other duties associated with water treatment works.

In addition to the salary quoted, there are extra benefits, including free family passages, children's school passages, paid leave, children's educational allowances, subsidised accommodation, free medical attention, income tax at low local rates and a terminal gratuity of 25 per cent. Appointment will be on agreement for 2½ years.

For further particulars you should apply, giving brief details of experience to:

crown agents

M Division, 4 Millbank, London SW1P 3JD, quoting reference number M/3B/731207/NE. (2594)

Research opportunities for graduates

The Laboratory. Our Research Laboratory of 1,350 needs to keep pace with the requirements of the Unilever world-wide food business. We require three first degree graduates, with or without additional experience, to work at Welwyn in our Dairy Division, which has a staff of about 70 people and services the needs of the Chilled Products and Ice Cream businesses.

Relevant scientific disciplines: Chemistry, Biochemistry, Physics, Food or Dairy Science.

Vacancy CWA 198. One vacancy occurs in product development to assist in devising and processing frozen or chill concepts to pilot plant scale. This work will require the successful candidate to acquire an understanding of the scientific principles of the products, since an important objective in the totality of our work is to relate product development with the background work also being undertaken.

Vacancy CWA 203. It is in the background area where the other two vacancies occur. One involves assisting in a study of the role and function of proteins, whereas the other is assisting with studies of the interactions of the various components in product systems through processing and in the final product. No previous experience in any of these areas is necessarily required, since suitable training will be given on the job. A good scientific approach and clarity and accuracy in communications are, however, required.

Location. Welwyn, Hertfordshire, is approximately twenty miles north of London.

Applicants. should write for an application form and further details to: The Personnel Officer, Unilever Research, Colworth/Welwyn Laboratory, The Frythe, Welwyn, Herts.

Unilever Research
Colworth/Welwyn Laboratory

(2692)

UNIVERSITY OF WARWICK

RESEARCH TECHNICIANS—GRADE 3

The Department of Biological Sciences has vacancies for research technicians in the Virus Research Laboratory. The work involves the tissue culture of animal cells and the isolation and characterisation of nucleic acids. A knowledge of biochemical techniques will be a definite advantage. The posts are for contract periods of one to three years. Salary on the scale £1,650 by £54 to £1,920 p.a. Applications in writing as soon as possible, to the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 46/2T/74. (2575)

MASSEY UNIVERSITY

PALMERSTON NORTH, NEW ZEALAND

LECTURER/SENIOR LECTURER IN VETERINARY SURGERY

Applications from graduates in Veterinary Science are invited for a teaching position in Veterinary Surgery in the Department of Veterinary Clinical Sciences to commence as soon as possible. Applicants should have had postgraduate experience in veterinary surgery and, preferably, should hold a postgraduate qualification. Preference will be given to candidates who have been working in the field of anaesthesiology.

The successful applicant will be required to teach veterinary anaesthesiology to students in the third, fourth and fifth years of the course and will be responsible to the Head of the Department of Veterinary Clinical Sciences. The appointee will be expected to participate in other aspects of the course in veterinary surgery and will have some clinical responsibilities in the general servicing of the veterinary clinics and hospitals. Opportunities for research in the surgical field are available and the appointee may be required to supervise postgraduate students and conduct postgraduate courses in the area of his speciality.

Salary: Lecturer NZ$6,753 to NZ$8,568, Senior Lecturer NZ$8,718 to NZ$10,232. Reader/Associate Professor NZ$8,718 to $10,232.

Conditions of appointment and further details may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on August 16, 1974 (2589)

WITWATERSRAND

JOHANNESBURG, SOUTH AFRICA

LECTURER IN SEDIMENTOLOGY

Applications are invited for appointment to the above post. Duties are to be assumed on October 1, 1974.

Duties attached to the post will include teaching of sedimentology and aspects of oceanography. Research experience in advanced techniques of sedimentology will be a recommendation for appointment.

Salary will be in the range: R5,520 to R7,935, the initial salary will be determined according to qualifications and experience. Benefits include an annual bonus, pension and medical aid facilities, and a housing subsidy, if eligible.

Intending applicants should obtain the information sheet relating to this post from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, with whom applications should be lodged not later than July 31, 1974. Applicants in the U.K. may obtain the information sheet from the London representative, University of the Witwatersrand, 278 High Holborn, London WC1 to whom a copy of the application should be sent. (2613)

UNIVERSITY OF SYDNEY

LECTURESHIP IN VETERINARY PHYSIOLOGY

Preference may be given to an applicant interested in Endocrinology and Reproduction in the Female. Teaching duties, however, will cover any part of the undergraduate physiology course.

The appointment will be from January 1, 1975 or shortly thereafter. It is a permanent position but may be filled for three years in the first instance, with the possibility of permanency after that time, or in certain cases return fares.

Salary range, $A9,002 to A$12,352 p.a.

Applications including curriculum vitae, list of publications and names of referees to the Registrar, University of Sydney, NSW 2006, Australia, by July 31, 1974, from whom further information is available. Information also available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (2593)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London)

DEPARTMENT OF PHYSICS AS APPLIED TO MEDICINE

A Research Assistant is required for a period of one year to work with group investigating solid state (Xeroradiography and Ionography) X-ray imaging methods. After completion of one year the position may be transferred to that of Lecturer in the Department with special responsibilities for development work in the field of diagnostic radiology and teaching trainee radiologists, radiographers and M.Sc. students. Applications stating age, qualifications and experience together with curriculum vitae and the names and addresses of two referees to Professor J. F. Tait, Department of Physics as Applied to Medicine, (N) The Middlesex Hospital Medical School, Cleveland Street, London W1P 6DB. (2591)

MASSEY UNIVERSITY

PALMERSTON NORTH, NEW ZEALAND

LECTURER IN BIOPHYSICS OR PHYSICS

Applications are invited for appointment to a Lectureship in Biophysics of Physics.

The appointee will be required to assist with teaching and research in Physics or Biophysics within the Department of Chemistry, Biochemistry and Biophysics. The Department offers Science degree units in Physics, Honours Science degree units in Biophysics, and appropriate Physics courses for the applied faculties of Agricultural and Horticultural Science, Food Science and Biotechnology, and Veterinary Science.

Preference could be given to applicants with research experience in the field of molecular biophysics.

Salary: NZ$6,753 to NZ$8,568.

Conditions of appointment and details concerning the University may be obtained from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close in New Zealand on August 10, 1974. (2588)

JAMES COOK UNIVERSITY OF NORTH QUEENSLAND

Applications are invited for the following appointments:

LECTURER IN ENGINEERING (SYSTEMS)

Applicants should have a higher degree, preferably a Ph.D., with industrial and/or research experience in some fields of systems engineering. Some preference will be given to applicants with expertise in one of the following: Industrial Engineering, Process Engineering, and Environmental Engineering. The appointee will assist with undergraduate and postgraduate courses in Systems Engineering and undertake research in an appropriate field of study.

Applications close July 19, 1974.

LECTURER IN BOTANY

Candidates should have a special interest and research experience in some aspect of Plant Genetics, including Cytogenetics, Plant Breeding, Population Studies or some related field. The appointee will conduct undergraduate courses in the area of his specialisation and assist in the general teaching of the Department.

Applications close July 26, 1974.

Salary range: $A9,002 to A$2,352 p.a. plus locality allowance of $A142 p.a. for a married male, or $A71 p.a. for a single appointee. Conditions of appointment include F.S.S.U. superannuation, invalid pension scheme, housing assistance, study leave and allowance for travel and removal expenses on appointment.

Further details and application forms obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (2592)

ROYAL POSTGRADUATE MEDICAL SCHOOL

SENIOR TECHNICIAN

required in research laboratory of the Diagnostic Radiology Department, in collaboration with the Respiratory and Cardiovascular Research Laboratories. The research carried out in this department is largely of a physiological and radiological nature and there will be opportunity for further study, including work for a higher degree. Qualifications H.N.C. in physiological measurement/BSc. or equivalent; radiographic experience not essential. Salary in range £1,578 to £2,448 according to qualifications and experience.

Applications to the Secretary, R.P.M.S., Hammersmith Hospital, Du Cane Road, London W12 0HS, quoting ref. no. 12/102/N. (2590)

LIVERPOOL POLYTECHNIC

SCHOOL OF PHARMACY

SENIOR LECTURER OR LECTURER II IN PHARMACOLOGY

Application are invited from graduates in Pharmacy, Pharmacology or Toxicology for the post of Senior Lecturer or Lecturer II in Pharmacology. A higher degree is essential and relevant postdoctoral experience would be an advantage.

The person appointed will be expected to teach pharmacology to honours degree students and to engage actively in research, for which excellent facilities are available.

Salary: Senior Lecturer £3,525 to £4,212 p.a.; Lecturer Grade II £2,700 to £3,474 p.a.

Details available from Staff Office, Dept. N, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool, L3 9RH. (2599)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF MEDICINE

RESEARCH ASSOCIATE

Applications are invited for a postdoctoral post as Research Associate to assist in research into thyroid and pituitary physiology to be carried out in the Department of Medicine. Candidates should have experience in organ and tissue culture. Previous endoctrine experience would be an advantage. The appointment will be for a period of up to three years. Salary on the scale £2,118 by £129 to £2,247 by £165 to £2,412 per annum.

Further information may be obtained from Dr D. C. Evered, Department of Medicine, University of Newcastle upon Tyne, Royal Victoria Infirmary, Newcastle upon Tyne NE1 4LP, to whom applications providing the names of two referees should be submitted within three weeks of this advertisement. (2601)

Reckitt & Colman

Nutritionist

To join the Medical Department of a well established and expanding Pharmaceutical Division of this major British Company.

The successful applicant will join a highly qualified team of experienced professionals and will provide his or her professional contribution on all subjects relating to nutrition. Initial work will be in the field of infant nutrition, particularly premature infants an enonates, and will involve liaison with clinical research workers in centres throughout the U.K.

The demands of this job will require the successful applicant to be well qualified and experienced, preferably with a research orientated career background which will enable him or her to function effectively in an atmosphere of new ideas and creative work.

The appointment is located in Hull and the salary will be attractive.

Please write quoting Ref. U.83 for an application form to:

R. A. Sandow,
Divisional Personnel Manager,
Reckitt & Colman,
Pharmaceutical Division,
Dansom Lane, Hull HU8 7DS (2669)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF BIOCHEMISTRY

Applications, are invited for the post of Demonstrator or Senior Demonstrator in the Department of Biochemistry. The post is tenable from October 1, 1974, for one year in the first instance, renewable yearly though not normally more than twice. Salary scale £1,761 to £2,367 per annum with F.S.S.U. benefits.

Applications, together with the names of three referees, should be received not later than July 12, 1974 by the Registrar, The University, P.O. Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote ref RV/N/276097. (2598)

UNIVERSITY OF SOUTHAMPTON FACULTY OF MEDICINE MICROBIOLOGY

Senior Chief Technician

to establish a Research and Teaching Laboratory. The appointee will be aged between 25-40 and have had experience in one or several of the following fields; Immunochemistry, Virology, Chemical Microbiology or Clinical Microbiology. Whitley Council Conditions of Service and salary will apply. Further information from: Professor P. J. Watt, Faculty of Medicine-Microbiology, University of Southampton Medical & Biological Sciences Building, Bassett Crescent East, Southampton SO9 3TU. Telephone Southampton 559122, Ext. 8411.

Application forms and job description from the Personnel Officer, Southampton Health District, Tremona Road, Southampton SO1 6HU. Telephone 777222, Ext. 3651. Closing date: July 20, 1974. (2596)

ST. BARTHOLOMEW'S HOSPITAL, LONDON EC1A 7BE

SENIOR GRADE PHYSICIST

Applications are invited for the post of Senior Grade Physicist in the Department of Radiation Physics. The successful applicant will be deeply involved in the clinical work of the Radiotherapy Department, which employs a wide range of irradiation facilities (10kV to 15MeV X-rays and electrons). An interest in the advancement of treatment planning and the use of simulators is essential. A considerable portion of time will be spent on relevant research and development work. Lecturing to students is involved. Some experience of computers would be advantageous.

Salary will be in the range £2,964 to £3,843 per annum plus London Weighting.

Application (to be returned by July 12) to Personnel Department, (quoting ref PT/4564/N). (2603)

THE UNIVERSITY OF ADELAIDE

invites applications for appointment as a

READER IN THE FIELD OF ENVIRONMENTAL STUDIES

The University proposes to offer a postgraduate inter-disciplinary course leading to a Master's degree in Environmental Studies. The Reader will be Director of the course in Environmental Studies, and will have the responsibility of co-ordinating the teaching and research programmes of students taking the course.

Applicants should have academic attainments at a level that would fit them for appointment as a Reader in a relevant field in the sciences, (including the applied sciences) social sciences or the humanities. An interest and some experience in multi-disciplinary studies is essential.

Salary scale: $A16,389, wth superannuation on the F.S.S.U. basis.

Further information, including list of particulars required in an application, is available from the Registrar of the University or from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications should reach the Registrar, G.P.O. Box 498, Adelaide, South Australia 5001 not later than **July 26, 1974.** (2615)

Experimental Officer

Biochemistry

Pharmaceuticals Division have a vacancy for an Experimental Officer to work with a senior biochemist on rheumatoid arthritis.

We are seeking a candidate with a university degree or similar qualification, preferably with wide experience in biochemical and/or immunological techniques.

Pharmaceuticals Division is attractively situated in rural North Cheshire, within easy reach of main road and rail routes. Assistance given to married men in moving to this area is designed to attract and retain staff of high calibre.

Applications in writing, requesting an application form should be sent to:

Mr. M. F. Losse, Personnel Officer,
ICI Pharmaceuticals Division, Mereside,
Alderley Park, Macclesfield, Cheshire.

ICI Pharmaceuticals Division

(2694)

FOOD HYGIENE LABORATORY

A.I.M.D.T. with experience in Bacteriology. The laboratory is concerned with the routine surveillance of foodstuffs and the investigation of problems associated with food hygiene and food poisoning. The successful applicant will be encouraged to take part in research projects which include work on the many types or organisms now associated with food poisoning.

The laboratory offers good facilities for study towards the special examination in bacteriology.

Further information or arrangements to visit the laboratory can be made by telephoning the Head Technician, 205 7041, Extension 38. Application forms can be obtained from the Personnel Officer, Central Public Health Laboratory, Colindale Avenue, London NW9 5HT. (2600)

CHELSEA COLLEGE
UNIVERSITY OF LONDON
DEPARTMENT OF PHYSIOLOGY

We are looking for two GRADE 4 TECHNICIANS to take part in research and teaching activities. The main responbilities will be in the field of human physiology and in the organisation and running of the teaching laboratories. We would particularly welcome applications from persons with experience in human or animal physiology and from those who have an understanding of electronic apparatus and an ability to design and make both electronic and mechanical apparatus. Salary Scale: £2,023 to £2,338 per annum (including £175 London Allowance). Application forms from the Personnel Officer, (N) Chelsea College, Manresa Road, London SW3 6LX. (2602)

UNIVERSITY OF BATH
SCHOOL OF BIOLOGICAL SCIENCES
ASSISTANT EXPERIMENTAL OFFICER
ECOLOGY TEACHING PROJECT

An Assistant Experimental Officer is required for one year to assist in the development of materials and teaching methods for an introductory ecology course at University level. Applicant must have a degree in a Biological subject.

Salary in the range £1,524 to £1,794 per annum

Application forms, available from The Registrar(S), University of Bath, Bath BA2 7AY, quoting reference 74/105, should be returned as soon as possible. (2618)

THE UNIVERSITY OF ADELAIDE

Invites applications for appointment as a

SENIOR LECTURER IN SOCIAL BIOLOGY (HUMANITIES OR SCIENCES)

The appointment will be in a department appropriate to the interests of the successful applicant who will initially be required to teach a third-year part subject to students interested in both the biological and the humanities.

Salary scale: $A12,643 to $417 (1) to $416 (4) to $14,724; with superannuation on the F.S.S.U. basis. Initial salary will be fixed within the scale in accordance with qualifications and previous experience.

Further information, including list of particulars required in an application, is available from the Registrar of the University or from the Secretary-General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications, should reach the Registrar, G.P.O. Box 498, Adelaide, South Australia 5001, not later than **July 26, 1974.** (2617)

SUFFOLK AREA HEALTH AUTHORITY
IPSWICH HEALTH DISTRICT
THE IPSWICH HOSPITAL
PHYSICS DEPARTMENT
PHYSICIST

at the Ipswich Hospital, Anglesea Road Wing. Duties will be principally concerned with radiotherapy and nuclear medicine. Salary £1,497 to £2,694 p.a. Further details may be obtained from the Principal Physicist, telephone Ipswich 51021. Application forms are available from the Hospital Secretary, Ipswich Hospital, Anglesea Road Wing, Ipswich, Suffolk. Reference ARW/P/16 Nature. (2626)

UNIVERSITY OF GLASGOW
DEPARTMENT OF PATHOLOGICAL
RESEARCH ASSISTANT

Applications are invited for a research assistantship (3 years appointment) in the above department at a salary of £1,395 per annum. The sucessful candidate will be involved in an investigation of the metabolism of human plasma lipoproteins in health and disease, and should have a good honours degree in biochemistry or chemistry. The applicant may be enrolled for a Ph.D. in the University of Glasgow.

Applications, including a brief curriculum vitae and the names of two referees, should be sent to:
Professor H. G. Morgan,
Department of Pathological Biochemistry,
Royal Infirmary,
Glasgow G4 0SF. (2614)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL
(UNIVERSITY OF LONDON)

Department of Physics as Applied to Medicine

Applications are invited from good honours graduates or those expecting to graduate this year in Biophysics or related sciences, to study receptor mechanisms in single mammalian cells. An M.R.C. training scholarship is available and the successful applicant may register for a postgraduate degree. Applications including curriculum vitae and the names and addresses of two referees, to Professor J. F. Tait, (N) Department of Physics as Applied to Medicine, The Middlesex Hospital Medical School, Cleveland Street, London W1P 6DB by July 9, 1974. (2623)

WESTFIELD COLLEGE
(UNIVERSITY OF LONDON)
CHEMISTRY DEPARTMENT

Experimental Officers (two) are required for varied and interesting work, including steroid synthesis, on the Medical Research Council's Steroid Reference Collection. New graduates, holders of G.R.I.C. or H.N.C., or school-leavers (A-level) with qualifications including chemistry are invited to apply. Salaries: scales £1,679 to £1,939 (graduate) or £1,211 to £1,679 (junior). Applications, including names of two referees, or requests for further information, should be addressed to Dr. D. N. Kirk, Chemistry Department, Westfield College, (N), Kidderpore Avenue, Hampstead, London NW3 7ST. (2622)

Senior Pharmacologist

Our client is a major British Research Organisation with extensive expertise in the field of biomedical sciences. Its function is to employ the latest skills, facilities and equipment to carry out research projects under contract for industry, government agencies and international bodies.

The laboratories are already well established, and are committed to a substantial growth and development programme over the next few years. In this connection we seek an experienced pharmacologist to spearhead the existing pharmacology projects, and also to identify and exploit new business opportunities in the UK and overseas.

Much importance is attached to publicising the specialised techniques developed in the unit, which currently include facilities for advanced psychopharmacological studies in primates, sensitive test systems for assessing the abuse-potential of new drugs and cardiovascular pharmacology. The successful candidate will be encouraged to develop interrelationships with other specialist research units, both within the organisation and outside it.

Applicants should be graduates in pharmacology or a closely related subject, ideally with a Ph.D. and several years' post-graduate experience in industrial pharmacology. A specific knowledge of behavioural pharmacology would be of particular interest to our client. In addition, candidates should have an adaptable and outgoing personality, with the ability to sell their ideas and services.

Salary is negotiable within wide limits and will reflect the importance of this position. Benefits include a progressive contributory pension scheme with free life insurance, four weeks holiday and generous assistance with relocation expenses.

The laboratories are situated in pleasant countryside near a major University city.

Please write in complete confidence for an application form and further literature, or 'phone if you would like to discuss the position:

Mr. R. A. Forbes-Leith, Talentmark Limited,
King House, 5/11 Westbourne Grove,
London W2 4UA. Tel: 01-229 2266.

Talentmark
Biomedical and Scientific Consultants

(2685)

LONDON BOROUGH OF BROMLEY
ORPINGTON COLLEGE OF FURTHER EDUCATION

Required for September 1, 1974.

(1) Technician for BIOLOGY laboratory and to assist in the Chemistry laboratory.

(2) Technician for PHYSICS laboratory and to assist in the college workshop.

Salary: Technician Grade III scale, £1,416 to £1,644 by £105 London Weighting (under review). 36 hours per week Monday to Friday including one evening per week.

Further details and application forms from The Principal, Orpington College of Further Education, The Walnuts, High Street, Orpington, Kent. Telephone Orpington 39336. (2606)

SIR GEORGE WILLIAMS UNIVERSITY
MONTREAL, QUEBEC, CANADA
DEPT. OF BIOLOGICAL SCIENCES
THREE FACULTY POSITIONS.

Three faculty positions avalable, July 1, 1974; 1 Associate Professor ($15,400 to $17,000), 2 Assistant Professors ($12,000 to $15,00) depending upon experience and qualifications. Research oriented persons qualified to teach in one or more of the following areas will be considered: Embryology Plant Ecology, Biostatistics, Introductory Biology, Ph.D. required. Send resume and names of three references to: **Dr. H. Enesco, Chairman, Dept. of Biological Sciences, Sir George Williams University, Montreal, Que. H3G 1M8.** (2647)

TECHNICIAN (Qualified)

required for work in immunology in relation to renal disease. Experience in this field is not essential. Apply in writing stating age and giving details of education and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. R.U.3. (2646)

LA TROBE UNIVERSITY
MELBOURNE, AUSTRALIA
LECTURER/SENIOR LECTURER IN BIOCHEMISTRY

The Department is interested in making an appointment in one of the following areas: Biochemistry of Hormone Action, Biochemistry of Development or Differentiation.

Salary: Senior Lecturer — $A12,643 to 1 by $A417 to 4 by $A416 to $A14,724; Lecturer $A9,002 to 4 by $479 to 3 by $A478 to $A12,352.

Professor B. A. Stone, the Chairman of the Department of Biochemistry, will be in the United Kingdom from July 15, to July 26 and may be contacted through the Association of Commonwealth Universities.

Further information and application forms are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, La Trobe University, Bundoora, Victoria, Australia, 3083.

Applications, close on **July 27, 1974** (2659)

THE EDINBURGH SCHOOL OF AGRICULTURE
RESEARCH ASSISTANT

Applications are invited from Honours graduates in Microbiology or a related discipline for a research assistantship to work in the microbiology and biochemistry departments on silage deterioration studies financed by the A.R.C. The assistant will be expected to register for a higher degree.

Salary £830 by £40 to £910 plus F.S.S.U. and fees.

Further particulars from The Secretary, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG. (2636)

ROYAL HOLLOWAY COLLEGE
(UNIVERSITY OF LONDON)
EGHAM HILL, EGHAM, SURREY.
RESEARCH TECHNICIAN— CHEMISTRY DEPARTMENT

The following Research post supported by the F.R.C. and supervised by Dr. Paul Powell is available from October 1, 1974.

Technician Grade 3 with experience in the routine synthesis of organic compounds to work on mechanisms of reactions of nucleophiles with organic ligands co-ordinated to transition elements. Salary £1,650 by £54 to £1,758 plus superannuation. Applications together with names and addresses of referees should be sent to the Personnel Officer (N) as soon as possible from whom further details may be obtained. (2616)

UNIVERSITY OF GLASGOW
DEPARTMENT OF NATURAL PHILOSOPHY
DATA ANALYSIS UNIT RESEARCH TECHNOLOGIST

The unit has an IBM 370/145, and IBM 7040 and four Data General computers. To these are attached various devices to assist in the analysis of data from high energy physics experiments (bubble chambers, spark chambers, etc.)

A vacancy exists for a responsible post as deputy to the physicist in charge of the unit, to assist him in the design of such equipment, its implementaion and testing, and to help supervise the construction of the hardware. It is anticipated that the successful candidate will have a degree or similar qualification in electronics and several years experience designing computer hardware. Alternatively the position might attract a physicist with experience of similar work. Salary will be within the range £2,637 to £3,174 per annum of the Research Technologist scale of £2,637 to £3,921.

Applications, giving relevant particulars and the names of two referees, should be sent to Professor I. S. Hughes, Department of Natural Philosophy, The University, Glasgow G12 8QQ, before July 15, 1974.

In reply please quote Ref. No. 3494 M. (2662)

Experienced histopathologist in research

Join a team conducting histopathological research and safety evaluation tests on our new ethical and proprietary drugs – a critical factor in their development.

You will have considerable involvement in the planning of safety evaluation studies as well as contact with other departments covering a wide range of biological research. In your own field advanced techniques such as histochemistry and electron microscopy are available.

The products of our research have an international reputation; we also have a reputation for advanced thinking in professional development. We can therefore promise that your experience and abilities will be fully recognised, and that further training where appropriate in pathology and other aspects of safety evaluation, with opportunities to attend international meetings, will be available to broaden and progress your career.

Salary will be attractive, and benefits are excellent: contributory pension, welfare schemes, and expenses toward relocation with the choice of reasonably priced houses in town – Nottingham, Loughborough, Leicester – or in pleasant surrounding countryside.

Please write with details or telephone: John Mills, Fisons Limited, Pharmaceutical Division, Bakewell Road, Loughborough, Leicestershire. Loughborough 66361.

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH

BIOCHEMIST

Postdoctoral Position in Division of Molecular Pharmacology

A post-doctoral biochemist is required to participate in a study of the mechanism of action of dihydrofolate reductase and its inhibition by folate analogues. Applicants should have experience in techniques of protein chemistry. The appointment, which is for up to three years, is available from October 1, 1974 in the salary range £2,223 to £3,378 per annum plus £162 p.a. London Allowance. Superannuation provision under F.S.S.U.

Applications giving details of qualifications, research experience and the names of two professional referees should be sent to The Director, National Institute for Medical Research, Mill Hill, London NW7 1AA. (2638)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF ELECTRONICS

RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to work for a project on Computer Modelling Techniques. The research will involve development of computer models and optimisation studies of electro-chemical systems.

Applicants should possess or be about to complete, a good honours degree or equivalent in engineering, physics or chemistry. Salary will depend upon qualifications and experience, and could be up to £1,500. The successful applicant will be expected to register for a higher degree.

Applications, citing two referees, should be addressed to the Deputy Secretary's Section, The University of Southampton, Southampton SO9 5NH. Closing date July 12, 1974. Please quote ref. 247/R/Na. (2640)

ROYAL HOSPITAL FOR SICK CHILDREN
and
QUEEN MOTHER'S HOSPITAL
GLASGOW.

ASSISTANT CYTOGENETICIST, science graduate, required for Glasgow and West of Scotland Genetic Advisory Service, to work on the diagnosis of human chromosome aberrations. Experience in cytogenetics and cell culture desirable but not essential.

Further details may be obtained from the University Department of Medical Genetics (041-339 8888, Ext. 7117).

Applications, with full details of qualifications and experience, and names of two referees to Medical Administration Office, Royal Hospital for Sick Children, Yorkhill, Glasgow G3 8SJ. (2666)

THE UNIVERSITY OF SHEFFIELD
C.A.S.E. AWARD IN PHYSICAL CHEMISTRY OF MICELLES

Applications are invited from good honours graduates in chemistry or chemical physics, or those about to graduate in these subjects, for a C.A.S.E. award under the joint supervision of Dr. I. A. McLure (University of Sheffield) and Dr. D. G. Hall (Unilever Research, Port Sunlight).

The project will involve initially study of distribution of suitable solutes between an aqueous solution of a surfactant and an immiscible and unsolubilized solvent with the object of gaining an improved understanding of the nature of the interior of micelles. Applications, consisting of curriculum vitae and names of two referees, should be sent to Dr. I. A. McLure, Department of Chemistry, The University, Sheffield S3 7HF, from whom further details can be obtained. Please quote reference R101/G. (2632)

UNIVERSITY OF EDINBURGH
ROYAL (DICK) SCHOOL OF VETERINARY STUDIES
DEPARTMENT OF VETERINARY PHARMACOLOGY

LECTURER

Applications are invited from holders of registerable veterinary degrees for the post of LECTURER in the Department of Veterinary Pharmacology.

Salary will be on the scale £2,118 to £4,896 with placement according to qualifications and teaching experience, and with superannuation benefits.

This post involves teaching pharmacology and chemotherapy to under- and postgraduate veterinary students. Appropriate clinical and/or research experience is desirable. The successful candidate may if necessary, register for a higher degree.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL with whom applications (three copies) giving the names of two referees, should be lodged not later than July 27, 1974. Please quote reference number 1028. (2635)

UNIVERSITY OF YORK
DEPARTMENT OF BIOLOGY

TRIALS OFFICER

Applications are invited for the post of Trials Officer, vacant from October, 1974 for a period of three years, from graduates in agriculture, biology or forestry. The successful applicant will join a team concerned with various aspects of colliery spoil reclamation. The research will be supported by the Department of the Environment and will be directed by Dr. M. J. Chadwick.

The work involves the establishment and maintenance of field trials on colliery spoil sites throughout England and Wales and the main responsibility of the Trials Officer will be supervision of these.

Salary within the range £1,761 to £1,995, with F.S.S.U.

Three copies of applications, naming two referees, should be sent as soon as possible to the Registrar, University of York, Heslington, York YO1 5DD, from whom further particulars may be obtained. Please quote reference number 11/7053.

TWO POST DOCTORAL RESEARCH FELLOWSHIPS

Applications are invited for two post-doctoral Research Fellowships from those with previous research interests in ecological aspects of soil-plant relationships. The successful applicants will work as members of a team concerned with various aspects of colliery spoil reclamation.

The research will be supported by the Department of the Environment for a period of three years from October 1974 and will be directed by Dr. M. J. Chadwick.

Salary within the range £1,878 to £2,580, with F.S.S.U.

Three copies of applications, containing a curriculum vitae and the names of two academic referees should be sent as soon as possible to the Registrar, University of York, Heslington, York YO1 5DD. Please quote reference number 11/6021. (2627)

LIVERPOOL POLYTECHNIC
DEPARTMENT OF BIOLOGY

RESEARCH ASSISTANT

To investigate the invertebrate fauna of industrial waste heaps under the supervision of Dr. M. Luxton.

The successful applicant will be expected to register for a higher degree.

Salary scale: £1,353 to £1,644 per annum.

Application forms available from Staff Office, Dept. N, Liverpool Polytechnic, Richmond House, 1 Rumford Place, Liverpool, L3 9RH to be returned within 10 days of the appearance of this advertisement. (2667)

UNIVERSITY OF SUSSEX

RESEARCH FELLOWSHIP IN OBSERVATIONAL EXTRA-GALACTIC ASTRONOMY

Applications are invited for one post of POSTDOCTORAL RESEARCH FELLOW in OBSERVATIONAL EXTRAGALACTIC ASTRONOMY

from October 1, 1974, tenable for a period of one to three years.

The Research Fellow will be expected to collaborate with visiting faculty members based at the Royal Greenwich Observatory in carrying out spectrometric and photometric observations of extragalactic radio and X-ray sources in the Southern Hemisphere.

Commencing salary will be in the range £2,247 to £2,931, with F.S.S.U. benefits.

Further information can be obtained from Professor L. Mestel, Astronomy Centre, Physics Building, University of Sussex, Falmer, Brighton BN1 9QH, U.K., to whom applications, with the names of two or three referees, should be sent by July 19, 1974.

(2631)

UNIVERSITY OF LONDON

READERSHIP IN VETERINARY PHARMACOLOGY

at the Royal Veterinary College

The Senate invite applications for the above Readership. Salary scale £4,707 to £5,844 a year, plus £162 London Allowance. Applications (10 copies) should be received not later than August 23, 1974, by the Academic Registrar (N), University of London, Senate House, London WC1E 7HU, from whom further particulars may be obtained. (2672)

UNIVERSITY OF EDINBURGH

MARY DICK CHAIR OF VETERINARY ANATOMY

The University Court invites applications for the above Chair. The Department, of which the Professor is the Head, is in the Faculty of Veterinary Medicine and is one of eight Departments in the Royal (Dick) School of Veterinary Studies.

Applicants must have a full range of knowledge of Veterinary Anatomy including Veterinary Histology and Embryology and would also be expected to have specialised knowledge in one or more sections of this wide field.

The salary will be within the professorial range. Superannuation under F.S.S.U.

Terms and conditions of appointment together with further particulars may be obtained from the undersigned, with whom applications (twelve copies) giving the names of three referees, should be lodged not later than August 15, 1974. A candidate from overseas may submit one copy of his application.

Applications should be sent to The Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL. Please quote reference number 2/74. (2637)

Senior Toxicologist

The Toxicology area of the Research Department is expanding and an experienced Toxicologist is required to take charge of a new section. This will entail the planning, conduct and assessment of acute and chronic tests in rodents and some general pharmacological investigations. The person appointed will be expected to maintain close liaison with other staff concerned in the safety evaluation of new Medical, Animal Health and Crop Protection products, and to contribute towards technical documents for registration of such products in the U.K. and overseas. Publication of results and attendance at scientific meetings are encouraged.

The modern, well-equipped research laboratories and associated facilities are located in Nottingham.

Applicants must have a good honours degree in pharmacology or relevant biological science and, preferably, a postgraduate qualification. Experience of working in Toxicology and a high standard of scientific report writing are essential.

Starting salary is negotiable and will reflect qualifications and experience. Conditions of employment are attractive and include good profit sharing and contributory pension schemes. Assistance with relocation expenses will be granted where appropriate.

THE MACMILLAN COMPANY OF INDIA

Managing Editor

We are looking for a man to take over the direction of our rapidly expanding publishing programme in English and Hindi. We expect that the right candidate will have an Indian background, good university qualifications, some publishing experience and a knowledge of Hindi. Drive, organising ability, entrepreneurial flair and sound judgement are the most important qualifications. The post is based in Delhi.

Please apply in confidence to:—

Adrian Soar,
Macmillan Publishers Ltd.,
Little Essex Street,
London WC2R 3LF.

Sharad Wasani,
Macmillan Company of India Ltd.,
2/10A Ansari Road,
Daryaganj, Delhi 6.

(2671)

AARHUS UNIVERSITY
(DENMARK)

At the Department of Chemistry (in the newly formed Division of Biostructural Chemistry) an adjunkt/lektor position will be vacant on August 1st, 1974.

A molecular biologist/biochemist is wanted for the position to complement work in the biostructural group in cooperation with a.o. professor B.F.C. Clark. Applicants with research experience in the field of protein biosynthesis, and/or in enzymology would be preferred.

The successful applicant must, on equal terms with the other members of the group, share the teaching obligations—from first-year level to supervision of graduate students.

The appointment is on a scale equivalent to assistant/associate professor with a salary range 65.000–115.000 Dkr.

Applications containing curriculum vitae, information on scientific and educational activities, a list of publications plus wherever possible 3 copies of published material, and any additional information relevant for the evaluation of the applicant's scientific and educational qualifications should be sent to the Faculty of Science, Aarhus University, Ndr. Ringgad 1, 8000 Aarhus C., Denmark, before August 1, 1974.

UNIVERSITY OF WESTERN AUSTRALIA
PERTH

PHYSICAL SCIENCES LIBRARIAN

A person with suitable qualifications and experience is required towards the end of 1974 for the above position which is rendered vacant by the present holder proceeding overseas. The Physical Sciences Librarian is responsible, under the direction of the University Librarian, for the Mathematics and Physical Sciences Library and the Science Reading Room. The Mathematics and Physical Sciences Library contains the bulk of the University's holdings in those subjects and is designed primarily for the needs of senior students and staff. The Reading Room holds the undergraduate collection.

Ideally, candidates should possess a degree in science or engineering, professional library qualifications and experience in a university or science library, but consideration will be given to graduates in other fields who possess considerable experience in scientific libraries or to science graduates without library experience who have a genuine interest in scientific information services. As the appointee will be expected to keep in touch with new developments in scientific information, experience or interest in the application of computers to libraries will be an advantage. Further details of duties and responsibilities can be obtained from the University Librarian.

The appointment will be made according to qualifications and experience either in the Librarian's salary range (based on that of a Lecturer), at present $A9,002 to $A11,396 pa. but currently under review, or in the Assistant Librarian's range of $A7,247 to $A9,578 p.a. Benefits include superannuation similar to F.S.S.U. fares to Perth for appointee and dependent family, removal allowance, annual and long service leave plus, in special circumstances for a Librarian, study leave.

Applications in duplicate stating full personal particulars, qualifications and experience should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australian, 6009, by **July 13, 1974.** Candidates should request three referees to write immediately to the Staffing Officer.

Conditions of appointment may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (2657)

Hormones and Liver Glycogen Project

Assistant Research Officer required to join in study of Hormonal Control of Liver Meabolism. Post would suit graduate with interest in biochemistry. Initial salary £1,296 p.a. (scale under review). Written applications to Departmental Superintendent, Biochemistry Department, Imperial College, London SE7 2AZ. (2642)

THE UNIVERSITY OF OXFORD POST-DOCTORAL ASSISTANTSHIP IN ORGANIC CHEMISTRY

Applications are invited for an S.R.C. supported postdoctoral post concerned with the synthesis of functional surfactants for selective catalysis of organic reactions. A background in organic synthesis or mechanism is desirable. Appointment would be for one year in the first instance, commencing around October 1, 1974, on the salary scale £1,821 to £2,058 (according to age) (under review) plus F.S.S.U. Applicants should forward a curriculum vitae together with the names of two referees to Dr. J. M. Brown, The Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, as soon as possible, and before August 15, 1974. (2689)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for two posts of

RESEARCH ASSISTANTS

to work on Nutrient Cycling in Freshwater Ecosystems.

Starting date October 1, 1974. Salary around £1,500 but applicants registering as full-time students for a higher degree will be paid at the studentship equivalent rate.

Further particulars are available from The Secretary, The University, Dundee DD1 4HN, to whom applications (quoting Ref. Est/43/74J and naming 2 referees) should be sent as soon as possible. Informal enquiries may be made to Professor W. D. P. Stewart at the Department of Biological Sciences. (2678)

PORTSMOUTH POLYTECHNIC
SCHOOL OF PHARMACY

LECTURER II IN PHARMACOLOGY

Applications are invited from pharmacists or pharmacologists to participate mainly in the teaching of Pharmacology to students of the Pharmacy degrees and the Honours degree in Pharmacology, and to assist with the teaching of other courses in the School of Pharmacy. A higher degree together with teaching or research experience is desirable. Excellent research facilities are available.

Salary scale: £2,700 to £3,474 per annum.

Application forms and further particulars may be obtained from the Staff Officer, Portsmouth Polytechnic, Alexandra House, Museum Road, Portsmouth PO1 2QQ, to whom completed applications should be returned by July 8, 1974. Please quote reference R76. (2663)

PRODUCTIVE DEVELOPMENT SCIENTIST

Required by Manufacturers producing mainly beverages with malt extract and also new instant meals.

Successful applicant will be responsible for reviewing and improving recipes of these products. Salary £3,000 up. Location: Herts.

Please apply to:
TUDOR APPOINTMENTS
11 Muswell Hill, N10 3TH
Tel: 01-444 9121 (24 hrs)
(2664)

PAPUA NEW GUINEA UNIVERSITY OF TECHNOLOGY
DEPARTMENT OF CHEMICAL TECHNOLOGY

SENIOR LECTURER

The Department of Chemical Technology offers a first degree course in Chemical Technology with specialisation in food technology, mineral processing and industrial chemistry. It is also responsible for the teaching of Chemistry to engineering students and for the operation of the University's Analysis Laboratory, which offers a wide range of analytical services on a commercial basis.

In 1975 the Department will be housed in a new biulding and associated with the Department of Forestry in a School of Natural Resources and with the Faculty of Agriculture of the University of Papua New Guinea.

Applications are now invited for the position of senior Lecturer, which is available immediately. Applicants should have a good degree in either Chemical Engineering or Applied/Industrial Chemistry as well as considerable industrial experience.

The successful candidate will be expected to play a major role in the development of the Chemical Technology degree course and in the setting up of various pilot plant operations. The Department already operates a small tannery and food and mineral processing programmes are being drawn up. In-service training of students is stressed in the degree course and staff are encouraged to form close working links with those organisations and companies involved in the training programme.

Research work in the Department is mainly concerned with environmental impact studies or the development of original processing techniques. The Department is also interested in Community Development and Small Business Development work.

Salary range: $A9,967 to $A11,589 per annum. Allowances totalling a further $A860 per annum are payable in certain circumstances. Modern furnished housing is provided at a nominal rental. Superannuation may be provided.

Applications in duplicate should include particulars of age, nationality, maritl status, family if any, qualifications, experience, present post and the names and addresses of three referees from whom confidential enquiries may be made, and are required by **July 26, 1974.** They should be sent to The Registrar, The Papua New Guinea University of Technology, P.O. Box 793, LAE, Papua New Guineaa. An additional copy should be sent to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom further information may be obtained. (2658)

LECTURER IN EXPLORATION GEOCHEMISTRY

Imperial College of Science and Technology wishes to appoint a Lecturer in Exploration Geochemistry with effect from October 1, 1974. Practical and/or research experience in this field is essential and preference will be given to candidates who have gained this experience Post-Doctorally.

Commencing salary, according to age, qualifications and experience in the scale £2,118 to £4,896 p.a. plus £162 London Allowance and FSSU.

Applications, including curriculum vitae and the names of two referees should be made by July 31, to Professor J. S. Webb, Applied Geochemistry Research Group, Geology Department, Imperial College, London SW7 2BP. (2639)

UNIVERSITY OF BRISTOL

Postdoctoral Protein Crystallographer

Applications are invited for an S.R.C. post to work in the crystal structure of pyruvate kinase or phospho glucose isomerase. The research will involve the development of computer programs to handle data collected by an oscillation camera. The appointment is for a period of two years with an initial salary of up to £2,058 per annum depending on experience. Previous research experience in crystallography is essential.

Applications, including a brief curriculum vitae and names and addresses of two referees, should be sent to Dr. H. Muirhead, Department of Biochemistry, University Walk, Bristol BS8 1TD. (2651)

PLYMOUTH POLYTECHNIC

SCHOOL OF ENVIRONMENTAL SCIENCES

SENIOR LECTURER/LECTURER II IN POLLUTION ECOLOGY

LECTURER II IN ANIMAL PSYCHOLOGY

LECTURER II IN GEOLOGY

(1 year temporary appointment)

Preference will be given to candidates with teaching and research interests in air pollution.

Salary: £2,700 to £3,474 p.a. Lecturer II £3,535 to £3,915 to (3 by 90) to £4,212 p.a. Senior Lecturer.

Further details and application forms from:

The Establishment Officer
Plymouth Polytechnic
Plymouth PL4 8AA.

to be returned by July 9, 1974. (3661)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PURE AND APPLIED CHEMISTRY

C.A.S.E. AWARD

Applications are invited from candidates wishing to study for a Ph.D. with Professor N. B. Graham in Applied Chemistry on a programme in co-operation with the I.C.I. Corporate Research Laboratory at Runcorn. The Science Research Council have agreed to sponsor a candidate under their programme of Co-operative Awards in Science and Engineering to study "The utra-violet treatment of fabricated polyethylene".

The successful candidate, who must have a first or second class honours degree, will receive training and pursue researchIs in photochemistry and polymer fabrication and characterisation at the University of Strathclyde and at I.C.I.

Applications to Professor N. B. Graham, Department of Pure and Applied Chemistry, Thomas Graham Building, University of Strathclyde, 295 Cathedral Street, Glasgow G1 1XL. (2654)

Unique opportunities in Ireland

SCIENTIFIC AND TECHNOLOGICAL ANALYSTS

The National Science Council of Ireland invites applications from suitably qualified persons for employment as Scientific and Technological Analysts within its Secretariat.

Successful candidates will carry out detailed techno-economic analyses and prospective studies on the scientific and technological infrastructure in Ireland, aids and incentives for the development of science and technology-based industry and science and technology policies necessary to develop important areas of the economy.

Successful applicants will be 27-35 years of age with a University degree or equivalent in an appropriate discipline and at least five years relevant working experience.

Appointments will be on a contract of up to two years duration and remuneration will be in the range of £4,000-£5,500 per annum. These positions will be particularly attractive to Irish citizens interested in returning to a job in Ireland offering a high level development perspective. Opportunities exist for working closely with Industry, Research Institutes, Universities and other agencies concerned with scientific and technological development in Ireland, and with relevant organisations in Europe. Applicants who can and wish to make a contribution within the Secretariat before moving to another position within Ireland will be afforded every facility and encouragement to do so.

Interested applicants should write for further information to:—

THE SECRETARY GENERAL,
NATIONAL SCIENCE COUNCIL,
ST. MARTIN'S HOUSE,
WATERLOO ROAD,
DUBLIN, 4, IRELAND

All applicants and enquiries will be treated confidentially.

Closing date for receipt of applications: 1st September 1974. (2652)

OXFORD UNIVERSITY

DEPARTMENT OF EXPERIMENTAL PSYCHOLOGY

Applications are invited for the post of

RESEARCH ASSISTANT

to work on the relation between brain activity and behaviour. The post offers wide opportunities for a person interested in neurophysiology, pharmacology and behaviour. The salary will be on the D.R.A. II scale and the starting point will depend on qualifications and experience.

Applications and requests for further details should be sent in writing to Dr. E. T. Rolls, Department of Experimental Psychology, South Park Road, Oxford OX1 3PS. (2676)

DEPARTMENT OF BIOLOGY

AMERICAN UNIVERSITY OF BEIRUT

is recruiting teaching research faculty for Fall (1974) in the following areas: general ecology, marine microbiology, plant physiology, and animal physiology (vertebrate and invertebrate). More than one opening is anticipated at Assistant or Associate Professor rank. Ph.D. required, post doctoral and teaching experience preferred. Travel, relocation and fringe benefits included. Applications with letters of reference should be addressed to Dr. Philip Basson, Chairman, Department of Biology, American University of Beirut, Beirut, Lebanon, with application copies to Personnel Services, American University of Beirut, 380 Madison Avenue, 22nd Floor, New York, N.Y. 10017. (2688)

Scientific Officers (Biometrics)

Applications are invited for two permanent and pensionable posts in the Biometrics Division of the Department of Agriculture.

Candidates must be under 27 years of age on 31 December, 1974, and have (i) a Degree, HNC or equivalent qualification in Computing, Mathematics or Statistics; or (ii) Part II of the Examination leading to Associateship of the Institute of Statisticians.

The Biometrics Division supplies a consultative service to research workers of the Department on the design and analysis of experiments and surveys. The posts in question will be concerned with (a) the programming of work in connection with computer-based sampling schemes to aid the study and control of Mastitis and Brucellosis; and (b) the application of computers to solve analytical problems and with documentation of computer packages.

Salary Scale (under review): £1,435 — £2,329.

Commencing salary will be related to qualifications and experience.

There are prospects of promotion to Higher Scientific Officer (£2,221 — £2,854), Senior Scientific Officer (£2,798 — £3,895) and Principal Scientific Officer (£3,715—£4,895).

Please write or telephone for an application form, quoting Ref. SB 175/74/N to Civil Service Commission, Clarendon House, Adelaide Street, Belfast BT2 8ND (telephone 44300, ext. 26). Completed forms should be returned to arrive not later than 16 July, 1974.

(2644)

NORTHERN IRELAND CIVIL SERVICE

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF APPLIED PHYSICS

LECTURESHIP

Application is invited for this appointment from physicists, preferably with a background in Solid State Physics or in Instrumentation.

The successful candidate will be expected to take part in the setting up of a research group in one of these fields. This group is to complement the present main research work of the Department, which is in the application of physics to problems of the natural environment and of (macro) biology. Some Industrial experience would be desirable.

Salary scale: £2,118 to £4,896 with placing according to qualifications and experience. F.S.S.U. benefits.

Application forms and further particuars (quoting 31/74) may be obtained from the Registrar, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW with whom applications should be lodged by July 8, 1974. (Applications from overseas candidates will be accepted up to July 16, 1974). (2655)

ROSKILDE UNIVERSITY CENTRE

DIVISION OF NATURAL SCIENCES

CHAIR OF BIOLOGY

Applications are invited for the chair of Biology from zoo-physiologists with experience in general physiology and human physiology.

Applicants with experience in physically oriented physiology will be preferred.

For further information, please write:

Division of Natural Sciences,
Roskilde University Centre,
P.O. Box 260,
4000 Roskilde/Denmark,

Deadline of applications August 2, 1974.

(2650)

CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, MANCHESTER M20 9BX PATERSON LABORATORIES

(Director: Professor L. G. Lajtha, M.D., D.Phil., F.R.C. Path.)

A vacancy exists for a person with a good honours degree in the biological sciences to investigate the nature of the target cells in experimental murine leukaemogenesis using a variety of techniques including surgery, transplantation and immunological procedures. The person appointed would work in collaboration with the divisions of Carcinogenesis, Haematology and Immunology. There will be an opportunity to register for a higher degree and the salary will be according to current MRC scale for research studentships.

Applications in writing, together with the names of two referees, should be sent forthwith to the Director. Ref. 74/26.

(51704) (2681)

ULSTER: THE NEW UNIVERSITY

EXPERIMENTAL OFFICERS

Applications are invited for two posts:

SCHOOL OF BIOLOGICAL AND ENVIRONMENTAL STUDIES
Ref: 74/93

The Experimental Officer will manage the School's scanning and transmission electron microscope facilities and will be expected to maintain the equipment, instruct users and assist in research programmes.

Applicants should be graduates (or equivalently qualified) and postgraduate experience in biological electron microscopy would be an advantage.

SCHOOL OF PHYSICAL SCIENCES (CHEMISTRY)
Ref: 74/94

The Experimental Officer in Chemistry will participate in a programme of biosynthetic research in collaboration with Professor M. F. Grundon and Dr D. M. Harrison.

Applicants should have a Ph.D. in organic chemistry or equivalent research experience.

Salary scale (under review with F.S.S.U.): £1,929 to £2,718 per annum.

Further particulars and application forms (quoting appropriate reference number) should be obtained from The Registrar, The New University of Ulster, Coleraine, Northern Ireland to whom completed applications, including the names and addresses of three referees, should be returned not later than July 31, 1974. (2653)

N.M.R. SPECTROSCOPIST

The role of the Analytical Chemistry Department within our Central Research Division is to devise and develop new techniques to control potential new drugs from discovery to marketing. A principal aim is the generation of technical data in support of submissions to world-wide regulatory agencies.

To maintain the high standard of supporting data required, we need an additional postgraduate Chemist, whose main responsibility will be the supervision of two 60 MHz Spectrometers in the NMR laboratory. Planned expansion includes 100 MHz proton and fourier transform facilities for carbon—13 work. The job involves working with a large number of research and development staff on a variety of problems arising from synthetic organic chemistry programmes.

The successful applicant will have a Ph.D. in Organic/Physical Chemistry; most probably with a heavy emphasis on NMR Spectroscopy, and a keen interest in the application of NMR Spectroscopy to the structural elucidation of complex organic molecules. A reasonable knowledge of other modern analytic techniques is desirable.

Our laboratories are situated in a pleasant rural/coastal area at Sandwich, Kent.

Our conditions of employment include a free pension and death benefit scheme, assistance with removal costs (where appropriate), bonus and flexible working hours.

Pfizer

Applications are invited from Chemists with not more than two years post-doctoral experience, and should be addressed to:
D. W. Sells, Personnel Manager, Central Research,
PFIZER LIMITED, Sandwich, Kent CT13 9NJ.

(2695)

AUSTRALIA
PUBLIC SERVICE OF VICTORIA
DEPARTMENT OF CROWN LANDS AND SURVEY
ROYAL BOTANIC GARDENS

SENIOR BOTANIST

REF. NO. (S/O1)

Yearly Salary: $A10,449 minimum; $A11,017 maximum.

Duties: To identify, classify and survey plants and to assist in the preservation and care of herbarium specimens. To conduct research and other duties as directed.

Qualifications: An approved degree in Science with a major in Botany and research experience in biosystematics and taxonomy is preferable.

Applications, quoting reference number (S/O1), should be addressed to the Secretary, Public Service Board of Victoria, State Public Offices, No. 1 Treasury Place, Melbourne, 3002, Australia, by not later than 9.30 a.m. on Wednesday, 7 August 1974, together with statements of experience and qualifications and date and place of birth. (2648)

INSTITUTE OF NEUROLOGY

requires TECHNICIAN to assist in Muscular Dystrophy Dept. in Biochemical Studies of Muscle.

Qualifications: H.N.C. preferable but not essential. Salary: University scale from £1,440 to £1,845 plus £126 L.A. Applications in writing giving qualifications, experience and names of two referees to: Dr. R. Yasin, Muscular Dystrophy Research Laboratories, National Hospital, Queen Square, London WC1N 5BG. (2673)

JUNIOR TECHNICIAN

required for Department of Histopathology to assist in research on multiple sclerosis and immunity in relation to the nervous system. O.N.C. or Science A levels an advantage. Apply in writing to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, giving details of age, qualifications and experience, if any, and quoting Ref. H.P.I. (2687)

THE INTERNATIONAL LABORATORY OF MARINE RADIOACTIVITY OF THE INTERNATIONAL ATOMIC ENERGY AGENCY IN MONACO HAS AN OPENING AT THE P-1 LEVEL.

The successful candidate should have a knowledge of and some experience in Marine Radioecological Research. Familiarity with radiochemical techniques employed in the determination of transuranic radio-nuclides is desirable. Ph.D. or equivalent in chemistry or chemical oceanography necessary.

Emoluments in the region of U.S. $10,994. Allowances for dependent spouse and children. Travel and removal expenses paid. Fixed term appointment two years. Send curriculum vitae to Division of Personnel, International Atomic Energy Agency, P.O. Box 590, A-1011 Vienna, Austria, not later than thirty days from today. (2677)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PURE AND APPLIED CHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the position of Postdoctoral Research Assistant in the Chemical Technology Section. The successful candidate will work with Professor N. B. Graham on a research programme involving synthetic and morphological studies of novel polymeric systems.

The position will appeal to candidates with both enquiring minds and experimental skills who like to pursue basic research which is clearly relevant to industrial or biomedical applications.

The position is initially tenable for two years with a salary of £2,247 during the first year. F.S.S.U. benefits.

Applications (quoting R19/74) with names of three referees to Professor N. B. Graham, Department of Pure and Applied Chemistry, Thomas Graham Building, 295 Cathedral Street, Glasgow G1 1XL. (2656)

UNIVERSITY OF READING

RESEARCH ASSISTANT

required for two years in Department of Botany to work under the direction of Dr. M. W. Dick, on the ecology of Mucorales in aquatic ecosystems. Applicants should have a good honours degree in Botany or Microbiology. Salary approximately £1,300 p.a. depending upon age and experience. Apply as soon as possible with curriculum vitae and names of two referees and quoting ref.: MN 27, to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH, from whom further particulars may be obtained. (2683)

Queensland Agricultural College

(A Multi-discipline College of Advanced Education)

APPLICATIONS: are invited for appointment to the following positions in the Department of Plant Industries:—

LECTURER IN ORNAMENTAL HORTICULTURE

LECTURER IN HORTICULTURAL AGRONOMY

SALARY RANGE: Min. $8,698—Max $11,982 per annum.

(A commencing salary above the minimum of the range may be paid depending on qualifications and experience of the successful applicant)

QUALIFICATIONS: For both positions, the possession of an appropriate degree is essential, with major studies in Horticultural Science and/or allied subjects. Applicants should have had professional experience in ornamental or environmental horticulture in the one case and horticultural agronomy, preferably with vegetable crops, in the other.

Preference may be given to an applicant who holds a higher degree and who has completed a relevant and recognised course of training as apart from studies within a basic degree course. General personal suitability and ability in teaching are also required.

GENERAL: The College is located 90 km west of Brisbane in the rich sub-tropical Lockyer Valley. Tropical and temperate, arid and humid, environments are within easy access. There is extensive vegetable production for processing and the fresh market in the Lockyer Valley and adjacent areas.

The College will pay fares and assist with removal expenses for the succcessful applicant and family, and may assist in providing temporary accommodation.

APPLICATIONS: Containing full particulars of name, address, date of birth, marital status, qualifications, experience, present employment and furnishing the names of two refereees should be forwarded to the Registrar, Queensland Agricultural College, Lawes, Q'ld, 4345 by August 10, 1974.

The successful applicant will be required to take up duties prior to the commencement of the 1975 academic year in February. (2670)

THE ROYAL VETERINARY COLLEGE

(University of London)

Division of Paraclinical Studies

DEPARTMENT OF PATHOLOGY

LECTURER IN VIROLOGY

Applications are invited from veterinary and science graduates for the newly-created post of Lecturer in Virology which is available from October 1, 1974.

Candidates should have considerable postgraduate experience in animal virology and possess a Ph.D. or equivalent degree. The appointee will be required to participate in teaching virology and virus diseases at the undergraduate and postgraduate levels. Strong research interests are essential; good facilities available, including supply of gnotobiotic animals. Prospective applicants are invited to contact Professor W. Plowright for further information.

Salary scale: 2,118 to 4,896 plus London Allowance (under review) at present £162 per annum, plus threshold supplement. Initial salary according to qualifications and experience. Superannuation under F.S.S.U.

Application form and further details available from Assistant Secretary (Personnel) (N). The Royal Veterinary College, Royal College Street, London NW1 0TU. **Closing date for applications:** August 19, 1974. (2674)

FELLOWSHIPS AND STUDENTSHIPS

UNIVERSITY OF BIRMINGHAM FACULTY OF MEDICINE AND DENTISTRY

DEPARTMENT OF PHYSIOLOGY

Applications are invited for a POSTDOCTORAL RESEARCH FELLOWSHIP to collaborate in a study of the physiological and pharmacological regulation of renin release under the supervision of Dr B. Singer.

Starting salary up to £2,553 p.a. plus F.S.S.U., depending on age and experience.

Applications, with curriculum vitae, naming two referees, should be sent to Professor S. M. Hilton, Head of the Department of Physiology, The Medical School, Birmingham L15 2TJ. (2476)

RESEARCH STUDENTSHIPS

Applications are invited for two three-year Research Studentships, tenable from October 1, 1974, at the M.R.C. Dunn Nutritional Laboratory, Cambridge, in the following areas:

(1) The relationship between protein metabolism and hormonal status in animals subjected to protein-energy malnutrition.

(2) The biochemical effects of riboflavin deficiency in an experimental animal, to relate the known parameters of subclinical riboflavin deficiency with biochemical lesions which may have pathological consequences. These studies will form part of a new programme, the aim of which is to examine various aspects of human nutritional status in relation to the water-soluble vitamins.

Applicants should have, or be expecting this summer, a first or upper second class honours degree, preferably in Biochemistry or Nutritional Science, and should send their curriculum vitae and names of two referees for (1) to Dr P. G. Lunn and (2) to Dr C. J. Bates, at the Dunn Nutritional Laboratory, Milton Road, Cambridge CB4 1XJ, not later than June 30, 1974. (2556)

UNIVERSITY OF EXETER

DEPARTMENT OF ENGINEERING SCIENCE

RESEARCH STUDENTSHIP

The Science Research Council has allocated a C.A.S.E. (Co-operative Award in Science & Engineering) studentship for three years (starting October 1974) to suitably qualified graduates interested in carrying out at the University of Exeter a "Study of deformation and failure of surface coatings on metals".

The co-operating body is the British Railways Board, Research & Development Division, Derby.

The value of the award is not less than £695 or £540 (for students living in parental home).

Applicants should possess, or expect to obtain in the Summer of 1974, a first or upper second class honours degree in Materials, Metallurgy, Physics or Engineering.

Further details and application forms can be obtained from:

Dr C. A. Brookes,
Department of Engineering Science,
University of Exeter,
North Park Road,
Exeter EX4 4QF.

Applications should be sent in as soon as possible. (2583)

North East London Polytechnic

Department of Biological Science

SRC Research Studentship in Plant Tissue Culture

Applications are invited for a **Science Research Council Studentship tenable from October 1, 1974.**

Applicants should be interested in working with plant tissue cultures. Areas in which work is in progress include the effect of cytokinin on protein synthesis and ultrastructure in soybean callus tissue; and on organogenesis and the isolation of variant cell clones in legumes and cereals. The successful candidate would be expected to work on one of the above projects under the supervision of Dr K. C. Short.

Further details may be obtained from the **Head of Biological Science Department, Ref. S/CF130, North East London Polytechnic, Romford Road, London, E15 4LZ.** (01-555 0811), to whom applications (curriculum vitae and names of 2 referees) should be made as soon as possible. (2607)

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL FELLOWSHIP IN SYNTHETIC ORGANIC CHEMISTRY

A fellowship is available now for a one-year period, although a starting date in October or later could be arranged. The appointment will be renewable for a second year. Salary in the usual range, £1,929 to £2,223 (under review) plus F.S.S.U.

Applications including the names of two referees should be sent as soon as possible to Professor R. C. Cookson, F.R.S., Department of Chemistry, The University, Southampton SO9 5NH, from whom further particulars may be obtained. (2579)

UNIVERSITY OF WARWICK

POSTDOCTORAL FELLOWSHIP IN BIOLOGICAL SCIENCES

Applications are invited for the above post to work on the isolation of messenger RNA for the small sub-unit of Fraction I protein. The work will be carried out in the Chloroplast Research Group under Dr R. J. Ellis. The appointment is for two years commencing October, 1974.
Salary in the range £2,118 by £129 to £2,412 p.a. with FSSU. Further details and application forms may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL, to whom completed applications should be returned by July 12, 1974. Please quote Ref. No. 46/2Q/74. (2611)

UNIVERSITY OF ST. ANDREWS

RESEARCH STUDENTSHIP

GATTY MARINE LABORATORY

Applications are invited for an S.R.C. studentship (£695) in the Laboratory from intending graduates interested in the study of invertebrate nervous systems; non-nervous conduction; sense organs; innervation of fish heart; pharmacology of small neurones. Application not later than July 5, 1974 to Professor M. S. Laverack, Gatty Marine Laboratory, St. Andrews. (2604)

Dunstaffnage Marine Research Laboratory

Applications are invited for a three year studentship to work on the role of meiofauna, particularly protozoa, in processes originating from the breakdown of cellulose fibre in marine sediments. The studentship carries with it a substantial equipment allowance. The successful applicant would be expected to read for a Ph.D. and would be required to satisfy University regulations for a higher degree. Application forms and further information can be obtained from the Director, Dunstaffnage Marine Research Laboratory, P.O. Box 3, Oban, Argyll PA34 4AD. (2568)

UNIVERSITY OF SOUTHAMPTON

FACULTY OF MEDICINE
CHEMICAL PATHOLOGY

RESEARCH STUDENTSHIP

Application are invited from biochemistry or physiology graduates, or from those who expect to graduate this summer for a Research Studentship leading to a higher degree. Applicants should have or expect to gain a good Honours degree. The successful candidate will work under the supervision of Professor K. G. M. M. Alberti in the area of intermediary metabolism in experimental diabetes or experimental liver disease. The post gives an excellent opportunity to gain experience in medical biochemistry.

The value of the award is £695 per annum plus approved fees but this is currently under review.

Applications and enquiries to Professor K. G. M. M. Alberti, Chemical Pathology, Southampton General Hospital, Tremona Road, Southampton SO9 4XY. (2578)

UNIVERSITY COLLEGE, CARDIFF

DEPARTMENT OF APPLIED MATHEMATICS AND ASTRONOMY

S.R.C. POSTDOCTORAL FELLOWSHIP IN ASTROPHYSICS

Applications are invited for an S.R.C. financed post-doctoral fellowship. The work is in collaboration with an experimental group at U.W.I.S.T. and is on the theoretical investigation of the optical properties of likely constituents of intersteller dust. The salary is commensurate with the lectureship scale and the post is for three years.

Applications including the names of two referees, to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Closing date two weeks from date of this advertisement. Please quote ref. 0597. (2630)

HERIOT-WATT UNIVERSITY

Applications are invited for a

CASE STUDENTSHIP

in the Department of Chemistry. The successful applicant will work in collaboration with Organon Laboratories Ltd. on new amino steroids in a series already established as possessing interesting pharmacological and clinical properties. The project will involve working both in the University and the industrial laboratories.

The University is situated in a parkland campus just outside Edinburgh.

The student, who should have a good Honours degree, will register for the degree of Ph.D. Enquiries should be sent to Dr M. M. Campbell, Department of Chemistry, Heriot-Watt University, Riccarton, Midlothian EH14 4AS. (2585)

SCIENCE RESEARCH COUNCIL

UK 48″ Schmidt telescope unit

vacancies for two Research Fellows

The Unit operates a 48-inch Schmidt telescope at Siding Spring, Australia. The primary purpose of the telescope, which has been in operation since July, 1973 is to survey the Southern sky to very faint limits in a blue waveband but time in conditions not suitable for survey work is used for other approved programmes.

POST I—SENIOR RESEARCH FELLOW/ JUNIOR RESEARCH FELLOW

An astronomer with research experience is required to join the group operating the Telescope at Siding Spring Observatory. The appointment will be at Senior Research Fellow or Junior Research Fellow level.

The primary duty of the person appointed will be to share in the demanding task of carrying out the survey to high standards of quality, including operation of the telescope and daytime photographic work. Ample opportunity exists, however, to make use of the survey material and non-survey telescope time for research purposes, and the Anglo-Australian 150-inch telescope nearby is expected to become available during 1975.

Return fares and removal expenses to Australia paid. Cost of living allowances are payable in Australia.

POST II—SENIOR RESEARCH FELLOW

An experienced astronomer is required at Edinburgh to be responsible to the Head of the Unit for the organisation and pursuit of research programmes and for some administration.

Survey plates are copied for world-wide distribution in an Atlas to be published jointly with the European Observatory who are carrying out a complementary survey in a red waveband. A limited number of glass and film copies of both surveys and of a quick ESO blue survey to less faint limits are also being distributed quickly to ESO and UK Observatories and Universities.

Copies of survey plates and original non-survey plates are returned to Edinburgh where they are available on application for loan to UK astronomers for research purposes. Some twenty research programmes are under way, many of them involving the Unit on a cooperative basis.

The duties of the astronomer appointed will be to ensure that existing research programmes are pursued with vigour, to initiate new research preferably in cooperation with University groups, and to administer the receipt, recording and distribution of plate material. A plate librarian is to be appointed to assist with the latter task together with routine photographic work.

Qualifications: Candidates for either post should possess a good honours degree in astronomy, together with research experience.

Salary: The fellowships will be for three years and will attract a fixed salary, determined according to age, qualifications, and experience on the appropriate scale: SRF £2,794 to £3,408
JRF £1,914 to £2,498

Provision can be made for F.S.S.U.

Application forms, which should be returned by July 5, 1974, are obtainable from: Mr A. Carter, Science Research Council, c/o British Rail Engineering Ltd., Swindon Works, Swindon SN1 5BW.
Tel: Swindon 26222 Ext. 22. (2624)

UNIVERSITY OF WARWICK

POSTDOCTORAL FELLOWSHIP IN BIOLOGICAL SCIENCES

Applications are invited for the above post to work on the mechanism of interferon induction by polynucleotides. The appointment is for three years commencing on October 1, 1974. Salary in the range £2,118 by £129, £2,247 by £165 to £2,412 p.a. with FSSU. Further details and application forms may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL, to whom completed applications should be returned by July 19, 1974. Please quote Ref. No. 46/Q/74. (2612)

UNIVERSITY COLLEGE, CARDIFF

DEPARTMENT OF APPLIED MATHEMATICS AND ASTRONOMY

Applications are invited for an S.R.C. financed post-doctoral fellowship on the theory of disordered semiconductors. The post is for three years and the salary will be commensurate with the lectureship scale.

Applications, including the names of two referees, to The Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Please quote ref. 0596. (2629)

UNIVERSITY OF STRATHCLYDE

Department of Pharmaceutical Chemistry

S.R.C. RESEARCH STUDENTSHIP ENZYME CHEMISTRY AND TECHNOLOGY

Applications are invited from candidates who have or expect to attain first or upper second class Honours degrees in Chemistry, Biochemistry or related disciplines. The research will be in one of the following areas: adsorption and micro-encapsulation of enzymes; membrane-dependence of intracellular enzymes; applications of circular dichroism; genetically determined enzyme polymorphism.

Applications and enquiries to Professor J. B. Stenlake, Department of Pharmaceutical Chemistry, Royal College, University of Strathclyde, 204 George Street, Glasgow, G1 1XW. (2610)

THE MICHAEL SOBELL CANCER RESEARCH FELLOWSHIPS OF THE CANCER RESEARCH CAMPAIGN

IN ASSOCIATION WITH THE ROYAL COLLEGE OF PATHOLOGISTS

Applications are invited for the above two Fellowships, endowed through the generosity of Sir Michael Sobell and intended for young graduate research workers to undertake laboratory research into some aspect of cancer. The Fellowships would normally be held for a period of from three to five years, and could include a period of work abroad. The salary would be appropriate to the age, qualifications and experience of the successful candidates, and funds would be made available for the running expenses of the work undertaken, and also, if applicable, for a limited amount of travel.

Applicants should submit their curriculum vitae and full details of their proposed project, and name both the Institute at which the work will be carried out and the Director who would supervise it. These details, with the names of three referees, should be sent to:

The Secretary General
Cancer Research Campaign
2 Carlton House Terrace
London SW1Y 5AR

and must reach him not later than July 29, 1974.

(2620)

POST DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a post-doctoral fellowship, tenable for one year, starting October 1974.

The project, directed by Dr. C. Descoins and Dr. P. Carle, involves an investigation on aggregating pheromones of European bark beetles. Candidates with a training in biochemistry or organic chemistry and a general interest in entomology preferred. Salary 30,000 French Francs per annum, plus 5,000 F.F. travel allowance.

The work will be carried out at Ecole Normale Supérieure (Paris) for 10 months and at Station de Recherches Forestières (Avignon) for 2 months.

Application, with curriculum vitae citing two referees, should be sent to Dr. Descoins, Chemistry Department, Ecole Normale Supérieure, 24 rue Lhomond, 75231-Paris, cedex 05, France. (2675)

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSICAL CHEMISTRY

S.R.C./C.A.S.E. RESEARCH STUDENTSHIPS

Applications are invited for two Ph.D. Research Studentships available from October 1, 1974.

1 Non-destructive characterisation of equilibrated alloy surfaces as a function of their bulk composition. This project involves Auger and photoelectron spectra of alloy surfaces and a new method in which the alloy surface is titrated using physical adsorption of gas. Supervisor—Dr. D. F. Klemperer
Co-operating Body—AERE, Harwell.

2 An investigation of the physical chemistry of moisture movement in porous media, with particular reference to the slip-casting process. Supervisor—Dr. J. M. Haynes
Co-operating Body—English China Clays, St. Austell, Cornwall.

Candidates must have a First or Upper Second Class Honours degree (or its equivalent) in chemistry or physics.

Write to the Secretary,
Department of Physical Chemistry,
University of Bristol,
Cantock's Close,
Bristol BS8 1TS (2619)

UNIVERSITY OF GLASGOW

Applications are invited for a research studentship to work on aspects of bacterial electron transport or nitrogen fixation. Candidates should have, or expect to obtain this year, a first or upper second class Honours degree in an appropriate subject, and the successful applicant will be expected to register for a Ph.D.

Applications stating age, qualifications, experience, and the names of two academic referees, should be sent as soon as possible to Dr. R. M. Daniel, Department of Cell Biology, University of Glasgow, Glasgow G11 6NU.

In reply please quote Ref. No. 3491M. (2634)

UNIVERSITY OF GLASGOW

DEPARTMENT OF NEUROLOGY

Institute of Neurological Sciences, Southern General Hospital, Glasgow.

RESEARCH STUDENTSHIPS

Applications are invited for two Research Studentships in the University Department of Neurology. The award is for one year initially with the possibility of renewal, at Research Council rates (increase pending). It is intended that the holder shall work for a higher degree of the University of Glasgow, (M.Sc. or Ph.D) and fees will be paid.

The holder will work upon biochemical and physiological changes associated with neurological diseases. Current projects include studies of anticonvulsants in epilepsy, and exercise. Applicants should have relevant qualifications. Candidates who have graduated in 1973 or are due to graduate in 1971 will be considered.

Applications, with curriculum vitae and the names of two referees, should be addressed to Dr. R. H. Johnson, Senior Lecturer, University Department of Neurology, Institute of Neurological Sciences, Southern General Hospital, Glasgow, G51 4TF.

In reply please quote Ref. No. 3492M. (2633)

A POSTDOCTORAL FELLOWSHIP (M.R.C.)

is available on a grant held jointly by the Departments of Physiology and Chemistry, to study mechanisms of sugar transport through biological membranes, and related phenomena. The major technique to be used will be N.M.R. Spectroscopy. Candidates with a chemical or bio-chemical background, preferably with N.M.R. experience, will be preferred. Please address enquiries to Professor M. C. R. Symons, Department of Chemistry, The University, Leicester LE1 7RH. (2628)

MEDICAL RESEARCH COUNCIL MINERAL METABOLISM UNIT, LEEDS

Applications are invited for an M.R.C. research studentship from graduates with a first or upper second class honours degree in physiology, biochemistry or pharmacology who wish to work for a Ph.D. The post will be tenable for three years from October 1, 1974 and will involve a study of calcium transport in muscle and bone.

Applications, giving details of age and curriculum vitae and quoting the names of two referees, should be made to Dr. W. G. Robertson, M.R.C. Mineral Metabolism Unit, The General Infirmary, Leeds LS1 3EX, before July 16, 1974. (2665)

STUDENTSHIPS

WYE COLLEGE
(UNIVERSITY OF LONDON)

Applications are invited from U.K. graduates or from those due to graduate in the summer of 1974 for Science Research Council postgraduate studentships tenable from October 1, 1974. A First or Upper 2nd Class Honours degree will be expected. The fields of research are as follows:

Department of Horticulture

Mechanisms controlling the inhibition of flowering or Studies on the role of leaves in photoperiodic reactions.

Department of Physical Sciences

A graduate in Chemistry to work on the synthesis of biologically active compounds.

Department of Biological Sciences

Detection of plant viruses in whole plants and protoplasts by fluorescence and immunology.

Department of Poultry Research

A graduate in physiology or zoology to work on the role of central transmitter substances in avian thermoregulation.

Value award: £695 per annum plus appropriate allowances and expenses.

Application to the Registrar, Wye College, Wye, Ashford, Kent TN25 5AH as soon as possible, and in any case not later than July 10, 1974. (2660)

IMPERIAL COLLEGE

DEPT. OF ZOOLOGY AND APPLIED ENTOMOLOGY

RESEARCH STUDENTSHIPS

(PH.D./M.PHIL)

Applications are invited from persons interested in postgraduate studentships (M.R.C. or S.R.C. funded) tenable in the department as from October 1, next. These studentships will be in the following broad fields and application should be made to the member of staff concerned at Dept. of Zoology, Imperial College, London SW7.

Protozoology, apply to Dr E. U. Canning

Insect behaviour, apply to Professor J. S. Kennedy

Helminthology, apply to Professor J. D. Smyth

Biology of leafhopper, apply to Dr N. Waloff

Applications by July 10.

(2643)

FRESHWATER BIOLOGICAL ASSOCIATION RIVER LABORATORY

N.E.R.C. RESEARCH STUDENTSHIP

A studentship is available from October 1, 1974, for research into the ecology of periphytic bacteria and yeasts in rivers under the supervision of Dr. J. H. Baker. Applicants must have or expect to obtain a good honours degree or the equivalent in an appropriate subject. Applications with curriculum vitae and names of referees, as soon as possible to the Secretary, Freshwater Biological Association, The River Laboratory, East Stoke, Wareham, Dorset BH20 6BB. (2679)

UNIVERSITY OF READING

DEPARTMENT OF PHYSILOGY AND BIOCHEMISTRY

The Ministry of Agriculture, Fisheries and Food is prepared this year to offer to a suitable candidate a Studentship tenable in the Department of Physiology and Biochemistry in the University of Reading. The value of the MAFF award in 1974 will normally be £695 per annum. The subject for research leading to a Higher Degree will be either: protein and amino acids in the growing rabbit or citrate and malate metabolism in the pregnant ewe. Work should start in October 1974 and applicants should hold at least an Upper Second Class degree in a suitable subject or hope to qualify this Summer. Further particulars may be obtained from: Professor C. Tyler, Department of Physiology and Biochemistry, The University Whiteknights, Reading RG6 2AJ. Ref. M.N.18. (2682)

UNIVERSITY COLLEGE CORK

Applications are invited for the following research appointment in Physical Chemistry, supported by external funds and tenable for one year from August 1974.

POST-DOCTORAL FELLOWSHIP IN DYNAMIC MASS SPECTROMETRY

Qualifications: Ph.D. in physical science, and additional research experience, preferably in the application of Rapid Scanning Mass Spectrometry or in interfacing mass spectrometers with a computer.

Duties: Full time research in the development of dynamic mass spectrometry and the application of mass spectrometry to study heterogeneously catalysed reaction.

Stipend: Within the range £1,800 to £2,250.

Applications with Curriculum Vitae and names of two referees to:

Professor of Physical Chemistry, University College Cork, Ireland.

Closing date July 15, 1974. (2690)

KING'S COLLEGE, CAMBRIDGE

FELLOWSHIP IN APPLIED PROBABILITY THEORY IN RELATION TO POPULATION BIOLOGY

Applications are invited for Fellowships in the above field, including population and human genetics, ecology, evolutionary theory, demography and stochastic diffusion processes to be held (from October 1975 or by arrangement) in the King's College Research Centre where computing facilities are available. Senior (age limit of 32) and Junior (age limit of 28 years and not more than about 3 years research experience) fellowships are available, together with an unrestricted fellowship which could be held by a senior worker on sabbatical leave. Maximum tenure, 4 years. Closing dates: **October 1, 1974,** for seniors and open; **November 15, 1974,** for juniors.

Salary: This is based on age and linked to the University lecturer scale. For an unmarried Fellow who is provided with free-accommodation in the College it ranges at present from about £1,500 at age 24 or below to £3,450 at age 36. Married Fellows receive £500 more, £625 if they have a dependent child or children.

Details of accommodation, research facilities, etc., from: The Convener, King's College Research Centre, King's College, Cambridge CB2 1ST, England. (2680)

MISCELLANEOUS

WEDDING

Bullard, Edward Crisp to Curnow, Ursula at Braintree Registry Office, June 17, 1974. (2693)

LECTURES AND COURSES

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF BIOCHEMISTRY

M.Sc. in BIOCHEMISTRY OF REPRODUCTION

A 12 months' course in Biochemistry and Physiology of Reproduction in the female mammal commencing October 1974.

The Course is designed for graduates in a Life Science, including Medicine and Veterinary Medicine, and consists of lectures, seminars and practical work in biochemistry and endocrinology as applied to the Study of Reproduction.

M.R.C. Scholarships available for suitably qualified applicants.

Applications should be made to Professor P. J. Heald, Department of Biochemistry, University of Strathclyde, 204 George Street, Glasgow, G1 1XW, from whom further information can be obtained. (2609)

FEBS Advanced Course No. 28

Rapid Reaction in Biochemistry

Rome, October 21—26, 1974

This Advanced Course, for 20-25 participants, will consist of lectures and practical demonstrations on methods for studying rapid reactions, application to biochemical systems, and analysis of kinetic data.

The Course fee of about DM 300 will include accommodation and meals.

Applications should be sent as soon as possible to: FEBS Advanced Course, c/o Prof. E. Antonini, Istituto di Chimica Biologica, Città Universitaria, 00185 Roma, Italy, with a copy to Prof. M. Gruber, Biochemisch Laboratorium, Zernikelaan, Groningen, The Netherlands. (2608)

PROTEIN SEQUENCING

EMBO and the Max-Planck-Gesellschaft sponsor jointly a course in protein sequencing to be held at the Max-Planck-Institut für Biochemie in Munich during November 10-16, 1974.

A purpose of the course is to assist laboratories wanting to take up sequencing, particularly automatic sequencing with sequenators. The course will consist of lectures and laboratory exercises and should impart a working knowledge of commonly used techniques.

Qualified to participate in the course are those who intend to do protein sequencing in the near future and who possess academic qualifications equivalent to or higher than a Master of Science degree.

Because of the intensive nature of the course the number of participants has been restricted to 12.

Board and lodging will be provided free of charge at the guest house of the Institute. Funds are available to cover substantially the travelling costs from and to the home country.

Applicants should give a brief curriculum vitae including academic qualifications, and should state the reason for wishing to participate in the course.

Enquiries and applications should be directed to the Course Director, Dr Agnes Henschen, Max-Planck-Institut für Biochemie, 8033 Martinsried bei München, West Germany.

Deadline for applications is September 1, 1974. (2672)

UNIVERSITY OF BRADFORD

Postgraduate School of Studies in Pharmacology

M.Sc. COURSE IN EXPERIMENTAL PHARMACOLOGY

Applications are invited from graduates in pharmacology, pharmacy or other appropriate subjects, for admission to the course starting in October, 1974. The course is of one year in duration and consists of four parts concerned with quantitative pharmacology, toxicology, psychopharmacology and a research project. The aim is to provide instruction and experience of research methodology as appropriate to the investigation of mechanisms of action of drugs. M.R.C. advanced course studentships are available for suitably qualified applicants. Further information and application forms are obtainable from the Secretary of the School of Studies in Pharmacology, University of Bradford, Yorkshire BD7 1DP. (2645)

GRANTS & SCHOLARSHIPS

THE WEST OF SCOTLAND AGRICULTURAL COLLEGE RESEARCH SCHOLARSHIPS

Applications are invited from graduates with a 1st or 2nd class Honours degree in an appropriate subject for a Research Scholarship leading to a University higher degree. Suitable projects are available in Agronomy, Animal Husbandry, Agricultural Economics and Marketing, Agricultural Botany, and Agricultural Zoology. The current value of the awards, which will be tenable for 2 or 3 years, is £750 p.a. plus fees and approved travel expenses.

Applications, stating age, qualifications and experience, together with the names of two academic referees, should be sent as soon as possible to the Secretary, the West of Scotland Agricultural College, Auchincruive, Ayr, KA6 5HW. (2574)

UNIVERSITY OF ABERDEEN MILNER SCHOLARSHIPS

Applications are invited from men only for two MILNER SCHOLARSHIPS tenable at the University of Aberdeen for research in:

(1) BACTERIOLOGY.

(2) PATHOLOGY (to join one of the research groups investigating "control of the mitotic cycle", "degradation of immunoglobulins" or "serum globulins and malignant cells".)

Applicants for the Bacteriology Scholarship must hold a good Honours Degree in Biochemistry or Microbiology; those for the Pathology Scholarship in Biochemistry or Zoology/Biology.

The Scholarships, each of £1,000 per annum, are tenable for one year from October 1974 in the first instance, but are renewable; any fees due from the holder will also be paid.

Applications (2 copies) to the Secretary, The University, Aberdeen, by July 12, 1974, stating qualifications and giving names of two referees. (2586)

MEDICAL RESEARCH COUNCIL

BLOOD PRESSURE UNIT

(GLASGOW)

Applications are invited for a Medical Research Council Training Scholarship in the above Unit. The award is for up to £695 per annum and the work caried out eligible for a Ph.D. The research envisaged is the biochemical investigation of peptide hormones (in particular antidiuretic hormone) produced by malignant neoplasms.

Applications, with curriculum vitae, to Dr. J. J. Morton, Medical Research Council Blood Pressure Unit, Western Infirmary, Glasgow G11 6NT. (2625)

MEETINGS

NUDE MICE—THEIR HUSBANDRY AND USE

An informal one-day meeting on the husbandry and use of the Nude mouse will be held at the Medical Research Council, Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, SM5 4EF (Tel: 01-643 8000) on Tuesday, July 16, 1974. Applications to attend this meeting (for which there will be no charge) are invited from interested research workers. Numbers will be restricted to a total of 40 people. Copies of the programme are available from Dr. M. Festing at the above address. (2691)

The THIRD INTERNATIONAL SYMPOSIUM

will be held at

University of Sussex, Brighton, England

JULY 6–12, 1975

Glycoconjugates: Functions in Animals

The programme will include symposia on the control of synthesis, glycoconjugate production by cultured animal cells, pathology of glycoconjugate metabolism, glycoconjugates in the neoplastic transformation.

In addition Workshops will include the chemistry and biology of transplantation antigens, glycoconjugates of viruses, nervous tissue and cell receptors.

Information is available from:

Dr R. C. Hughes
National Institute for Medical Research
Mill Hill, London NW7 1AA

Dr R. D. Marshall
Department of Chemical Pathology
St Mary's Hospital Medical School
Praed Street, London W2

Studies in History and Philosophy of Science

Studies in History and Philosophy of Science is a quarterly journal which analyses the genesis, evolution and logic of scientific thought. It attempts to unite historical and philosophical approaches to science.

Recent papers include:
Maxwell's Methodology and his application of it to Electromagnetism, A. P. Chalmers. **The Astronomy of Eudoxus: Geometry or Physics?,** Larry Wright. **Conceptual Structures and Scientific Change,** Garry Gutting. **Whewell's Theory of Scientific Language,** Morton L. Schagrin. **Speculation in Physics:** The theory and practice of **Naturphilosophie,** Barry Gower. **Feyerabend and Galileo: the interaction of theories, and the reinterpretation of experience,** Peter K. Machamer. Edited by Gerd Buchdahl, Reader in History and Philosophy of Science, University of Cambridge and Professor L. L. Laudan, Chairman, History and Philosophy of Science, University of Pittsburgh. Published by Macmillan Journals Limited.

Annual Subscription £8.50 (£9.50 U.S.A. and Canada). Prices applicable only to orders starting before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

A SHARP IMAGE FREE OF DISTORTION

Zeiss pocket magnifiers come in three sizes:

Single lens × 6	£9.13
Single lens × 10	£9.13
Double lens × 3 × 6 (and thus × 9)	£11.99

Made by Carl Zeiss of West Germany, these invaluable magnifiers are used in science, industry, medicine, map-reading, philately, electronics, geology, nature study etc etc all over the world. Beautifully made and remarkable value.

Prices include VAT and postage.

Send cheque or PO, or ask for a leaflet, to Carl Zeiss (Oberkochen) Ltd Degenhardt House 31-36 Foley Street, London W1P 8AP 01-636 8050 (15 lines)

ZEISS POCKET MAGNIFIERS

CHARLES C THOMAS • PUBLISHER

FISH CHROMOSOME METHODOLOGY *by* **Thomas E. Denton,** *Samford Univ., Birmingham, Alabama.* Divided into four general parts, the book includes an introduction to the classification and maintenance of fishes, how to obtain and present chromosome data, a check list of chromosomes containing the numbers and karyotypes from over 500 fishes, and a current analysis of the fish karyotype. *'73, 176 pp., 10 il., 1 table, $11.50*

METHODS OF MEDIA PREPARATION FOR THE BIOLOGICAL SCIENCES *by* **Joyce A. Stewart,** *Univ. of Tennessee, Knoxville.* This reference brings together in one book all of the so-called standard formulas for buffers, stains, reagents and indicators plus the in-between-the lines knowledge learned from trial and error experience. *'74, 108 pp., 5 il., $7.50*

RHEOLOGY OF BIOLOGICAL SYSTEMS. *Edited by* **Henry L. Gabelnick,** *National Institutes of Health, Bethesda, Maryland, and* **Mitchell Litt,** *Univ. of Pennsylvania, Philadelphia. (31 Contributors)* The rheological properties of blood, mucus, sputum, saliva and synovial fluid are discussed. The volume presents the proceedings from an interdisciplinary symposium on biorheology held in November, 1971, in San Francisco. *'73, 319 pp., 230 il., 25 tables, $16.95*

THE BOTANY AND CHEMISTRY OF HALLUCINOGENS *by* **Richard Evans Schultes,** *Botanical Museum of Harvard Univ., Cambridge, Massachusetts, and* **Albert Hofmann** *Sandoz Ltd., Basel, Switzerland. Foreword by* **Heinrich Kluver.** Directed primarily toward the botany and chemistry of hallucinogens, the book also considers ethnobotanical, historical, pharmacological and psychological aspects. *'73, 292 pp., 85 il., 5 tables, $14.75*

THE PRENATAL DIAGNOSIS OF HEREDITARY DISORDERS *by* **Aubrey Milunsky,** *Harvard Univ., Boston, Massachusetts. Foreword by* **John W. Littlefield.** Hereditary biochemical disorders, chromosomal abnormalities, sex-linked disorders and congenital malformations that can now be diagnosed *in utero* are discussed. Carrier detection in genetic disease is emphasized. *'73, 276 pp., 18 il. (2 in full color), 26 tables, $11.75*

HUMAN AND ECOLOGIC EFFECTS OF NUCLEAR POWER PLANTS *by* **Leonard A. Sagan,** *Palo Alto Medical Clinic, Palo Alto, California. Introduction by* **Rolf Eliassen.** *(15 Contributors)* The social factors surrounding nuclear power are discussed—damage to the environment, contamination of air and water, and the desire for wider participation in the decision-making in the use and controls put on nuclear power. *'74, about 540 pp. (7 x 10), 138 il., 86 tables*

ECOLOGY AND THE QUALITY OF LIFE. *Edited by* **Sylvan J. Kaplan,** *Chevy Chase, Maryland, and* **Evelyn Kivy-Rosenberg,** *Jersey City State College, Jersey City, New Jersey. (24 Contributors)* The contributors, representatives of a variety of professional disciplines, define the problem of ecology and the quality of life. They offer changes and improvements for a better future. *'73, 308 pp., 23 il., 11 tables. $17.50*

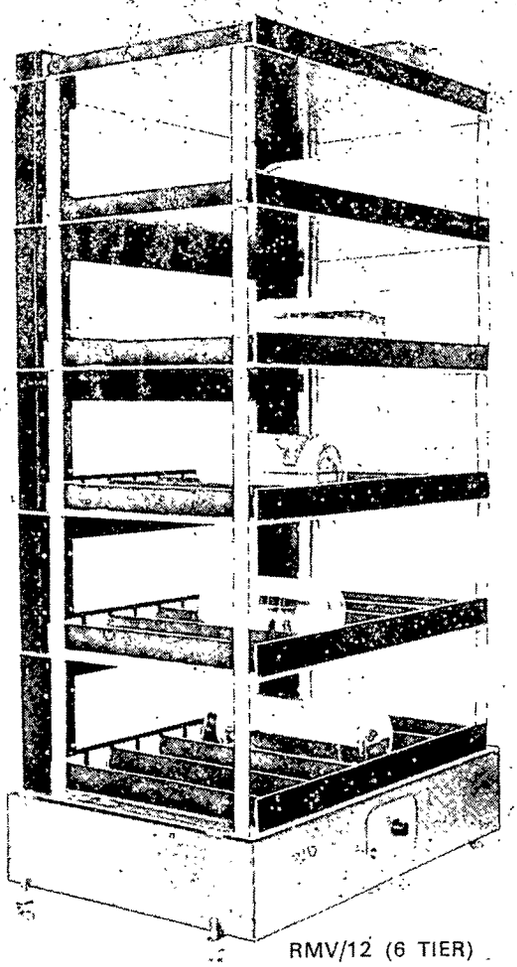
SPRINGFIELD • ILLINOIS • 62717

up to a six tier universal roller



Designed to meet the demands for the production of large quantities of cells for use in biochemical, microbiological and other relevant techniques.

The Luckham Universal roller has been manufactured so that the basic two tier model can have further tiers added to a maximum of six. This feature reduces to a minimum the space taken in the "hot" room or incubator.

The Universal roller is a slow variable speed machine for rolling bottles of 95mm to 100mm diameter or the Sterilin plastic vessels. Other sizes to special order. There is a choice of two motors:

The RMV/12/06 giving roller speeds of 0.146–0.6 rpm

The RMV/12/10 giving roller speeds of 2.47–10.0 rpm

RMV/12 (6 TIER)
